Poverty of Philosophy, Marx attempted for the first time positively to unfold the reproduction in thought of the real movement of capitalist economic forms. Albeit in a rudimentary form, this represents Marx's first attempt at a dialectical critique of political economy. In turn, the latter is revealed as the necessary scientific form of the proletarian consciousness that gives course to the practical critique of capital. Thirdly, as a necessary corollary of this, science ceases to be an abstractly contemplative enterprise. Marx's critique of political economy is not meant to provide another economic theory of bourgeois society, albeit from the perspective of the working class. From that very moment, Marx's scientific endeavour constituted an attempt at the positive investigation of the social determinations – and hence necessity – of the different forms of the political action of the workers aiming at the radical transformation of the capitalist mode of production. In brief, we shall see that interest in the question of the 'scientifically correct method' turns out to be not abstractly epistemological, but directly political in nature. Let us now turn to the discussion of each of these aspects of Marx's polemic against Proudhon.

The Dialectical Method as Logic in Proudhon

The first two sections of Marx's *The Poverty of Philosophy* comprise a reconstruction of Proudhon's arguments about the basic economic categories such as use value, exchange value and money. The gist of Marx's critique comes down to the following two aspects. In the first place, he demonstrates a lack of originality in Proudhon's ideas. In order to counter the latter's self-proclaimed originality, Marx resorts to some quotes from the classical political economists, particularly Ricardo, and demonstrates that the assertion that economists failed to deal properly with the 'opposition' between use value and exchange value is plainly false. In all this there is nothing particularly original in Marx's development itself and, fundamentally, he bases his economic analysis on the theories of the Ricardian school.

In the second place, Marx criticises Proudhon's absurdities about the opposition between an allegedly ethically ideal determination of value in labour time and its empirical determination through the contending wills of buyer and seller, which would lead to the deviation from the former due to the social power of direct exchangeability monopolised by money. According to Proudhon, it is not the exchange of commodities as such which lies at the basis of the capitalist exploitation of labour, but only its distorted concrete form of operation leading to unequal exchange. Therefore, Marx points out, Proudhon's deficient critical engagement with political economy actually justifies his ideological view of socialism as the realisation of the ideas of justice and equality springing from the determinations of the commodity form itself. Again, in order to refute Proudhon's assertions Marx does not offer any original analysis and limits himself to the claim that, far from being the law regulating the negation of present-day society, the 'law of value' actually is the adequate expression of the movement of social labour in its capitalist form.

> Ricardo shows us the real movement of bourgeois production, which constitutes value. M. Proudhon, leaving the real movement out of account, 'fumes and frets' in order to invent new processes and to achieve the reorganization of the world on a would-be new formula, which formula is no more than the theoretical expression of the real movement which exists and which is so well described by Ricardo … Ricardo's theory of value is the scientific interpretation of actual economic life; M. Proudhon's theory of values is the utopian interpretation of Ricardo's theory.[3]

In this judgement, Marx basically cites approvingly the political economists, only adding the critical insight that these social forms do not represent the absolute realisation of human individuality but its enslavement in alienated forms. In this sense, the realisation of the determinations of the 'law of value' can hardly be the basis of the emancipation of the workers.

> Thus relative value, measured by labor time, is inevitably the formula of the present enslavement of the worker, instead of being, as M. Proudhon would have it, the 'revolutionary theory' of the emancipation of the proletariat.[4]

In brief, in these first pages there is nothing significantly novel about Marx's critique of Proudhon. The interesting insights emerge when Marx turns to the discussion of the scientific source of the limitations suffered by Proudhon's critical approach to political economy. This source, Marx argues, is to be found in the defective way in which Proudhon tried to appropriate Hegel's dialectic in order to deal with the subject matter of political economy. The gist of Marx's attack against Proudhon is that far from developing a dialectical critique of political economy, the latter offers merely an idealist reconsideration of economic categories by subjecting them to an extrinsic application of the categories of Hegel's *Science of Logic*. According to Marx, then, the source of Proudhon's idealism lies in his reduction of the dialectic to another *logical method*, a ready-made set of formal rules of thinking to be applied to the object of cognition at stake or, more precisely, to the theoretical representations of it. Marx characterises Proudhon's account in the following way:

---

[3] Marx 1976b, pp. 123–4.

[4] Marx 1976b, p. 125.

> Economists explain how production takes place in the above-mentioned relations, but what they do not explain is how these relations themselves are produced, that is, the historical movement which gave them birth. M. Proudhon, taking these relations for principles, categories, abstract thoughts, has merely to put into *order* these thoughts, which are to be found alphabetically arranged at the end of every treatise on political economy. The economists' material is the active, energetic life of man; M. Proudhon's material is the dogmas of the economists.[5]

Note how Marx emphasises the importance of reproducing in thought the real movement of production relations, instead of dealing with the 'categories' of political economy in an allegedly 'dialectical' fashion. According to Marx, the economists at least take as their starting point the confrontation of the real movement of economic forms, that is, they face the 'active, energetic life of man'. Yet they do so not to ideally reproduce the real movement, but to construct a *theoretical representation* of it. In other words, what the political economists lack is a grasp of the 'inner connections' between the different forms of social relations. This is because they lack the 'genetic' approach of the dialectical method that is needed to account for the movement through which 'these [social] relations themselves are produced'.

It is precisely this genetic approach that Proudhon claimed to be developing regarding the subject matter of political economy. But Marx's point is that that was far from being the case. The reason for this is that Proudhon did not take the necessary starting point of any dialectical investigation, namely, the confrontation of the concrete forms of social reality themselves. Instead, Proudhon's 'dialectical' critique took as its starting point the 'dogmas of the economists'. And what he then did was simply to reorder those 'categories' according to allegedly dialectical criteria and relations, giving the *appearance* of a dialectical presentation. In other words, Proudhon uncritically took the economic categories, 'which are to be found alphabetically arranged at the end of every treatise on political economy', and reorganised them according to a 'dialectical logic'.[6] What in Hegel was developed with the profundity characteristic of great thinkers making real discoveries (namely, the general form of motion of the dialectical method), in Proudhon led to an unhappy marriage of 'bad philosophy' and 'bad political economy'.[7] Moreover, what in Hegel was justified in its own terms (that is, his engagement with pure thought forms or categories) and given an explicit idealism which saw logical forms as the essentialities of things, led Proudhon to antinomies and absurd conclusions. In other words, the problem with Proudhon was not the construction of an idealist speculative dialectic, but the fact that he did not offer even that. He just provided a reformulation of theses already formulated by the political economists in a dialectical jargon, utilising logical categories and forms of argument taken from Hegel's *Logic*. Marx's point is that, instead of a critique of political economy, Proudhon develops just another form of 'applied metaphysics', in which the specific movement of economic relations is seen as an immediate expression of the abstract form of the logical movement.

---

[5] Marx 1976b, p. 162.

It is important at this point to highlight that Marx did not object to the emphasis on the self-movement of real forms as the lesson to be drawn from Hegel. As evidenced by the following passage, Marx accepted that the most general determination of all reality is that it *self-moves*, in the specific sense that each form of the real carries the necessity to become another.

> All that exists, all that lives on land and under water, exists and lives only by some kind of movement. Thus, the movement of history produces social relations; industrial movement gives us industrial products, etc.[8]

In other words, Marx took on board Hegel's insight on the 'mediacy of all immediateness', albeit without the idealist mystical shell. In fact, the passage just cited is but a 'materialist' paraphrasing of Hegel's remark on the inner connection between immediacy and mediation in the introductory section dealing with the question of science's systematic point of departure in his *Logic*.

> Here we need only quote from it this, there is nothing, nothing in heaven, or in nature or in mind or anywhere else which does not equally con-

---

[6] Ibid.

[7] Marx 1976b, p. 109.

[8] Marx 1976b, p. 163.

> tain both immediacy and mediation, so that these two determinations reveal themselves to be *unseparated* and inseparable and the opposition between them to be a nullity.[9]

Understood dialectically, this can only mean that reality is contradictory, the movement of contradiction. In turn, I would like to argue that, for Marx, this can only mean, in its simplest form, the affirming through self-negation of real forms. Still, it is true that in the above passage Marx just argues that real forms exist through some kind of movement but does not explicitly tell us the general form that that movement takes. However, in another text of the same year Marx reiterated that insight about all real forms realising their determination through movement (or what he in this case called 'development'), but now specified its general form, namely, the affirming through self-negation. Hence he states in *Moralising Criticism and Critical Morality*:

> Any development, whatever its substance may be, can be represented as a series of different stages of development that are connected in such a way that one forms the *negation* of the other. If, for example, a people develops from absolute monarchy to constitutional monarchy, it *negates* its former political being. In no sphere can one undergo a development without negating one's previous mode of existence.[10]

But if the movement of contradiction is the 'rational kernel' that Hegel had discovered, what is wrong with the 'application' of this insight to the 'categories' of political economy? Precisely the idea that we are before an absolute *logical principle* that needs to be *applied* to *theoretical categories*, instead of the general form of motion of the real which we ideally grasp in the *specificity* of the particular different forms of 'all that exists'. In other words, what Marx criticises is the conversion of that simple truth regarding the general form of motion of reality into a logical category, in order to then account for every specific movement by recourse to an unmediated application of this most abstract determination. Self-mediation or self-movement is realised or exists in specific mediating forms. None of those more concrete mediations can be skipped over when facing a real form in order to cognise it and transform it. This means that there are no basic or general principles of thought (the unity of opposites, the negation of the negation, the transformation of quantity into quality, and so on) to be followed in order to *represent* reality more accurately than through formal logic. Contradiction simply means that every real form (whether natural or social) realises its qualitative determination by transforming itself into a more concrete form, that the process of determination is a process of becoming another, i.e. a movement of self-mediation.[11] As the form of movement, the 'inner life', of the concrete object that we want to appropriate by means of thought, it has to be followed in its specific modes of existence and development. This is why, for instance, Marx's *Capital*, as a critique of political economy, is not, *pace* Engels, an application of dialectical logic to political economy,[12] but the ideal reproduction of the real determinations of capital as the alienated social subject of bourgeois society, starting with its simplest mode of existence, i.e. the commodity. In short, although contradiction is the general form of movement of reality, this is not a general axiomatic principle which is unmediatedly 'applied' to whatever concrete form we are facing.[13] In fact, and despite Marx's own usage, I think that the very term 'application' should be dispensed with altogether when referring to the development of dialectical cognition. The dialectical method is concretely *set into motion* on each occasion when one wants to appropriate in thought the determinations of a concrete subject matter, in order to realise through our own transformative action the potencies immanent in the object of cognition at stake. Dispensing with the mediation of the latter in the name of correct methodological *rules* or ontological determinations is precisely what reduces everything to applied logic or metaphysics.[14] According to Marx, this was the mistake made by both Hegel and Proudhon.

[11] Iñigo Carrera 2008, pp. 259–60. This is one of the elements of the rational kernel to be found in Hegel's *Logic*, which he explicitly discusses in the pages on the dialectic of the finite and the infinite. *Pace* Colletti (1973, pp. 14–15), Hegel is not demonstrating the idealistic 'annihilation of matter'. Instead, what he is simply expounding in those pages is that real forms of 'being' affirm through self-negation. It is in that specific sense that, according to him, reality is the movement of contradiction. To put it differently, Hegel's point in those pages is just to say that the true infinite is nothing but the immanent *self*-movement of finite forms of being (Hegel 1999, pp. 129–31; Houlgate 2005, p. 429). For a further elaboration of this point, see Caligaris and Starosta 2014.

[12] Engels 1987, p. 343.

[13] All this raises the following question, namely, how the most abstract determination of reality as the movement of contradiction is discovered. In other words, the question of the necessity of process of determination itself still needs to be addressed. I cannot elaborate on this issue here. Later in this chapter, I explain that it can never be a dogmatic, metaphysical starting point, but rather the result of the process of dialectical *analysis*, which constitutes the first stage of a scientific investigation that always has the question of the conscious organisation of transformative action as its starting point. As the simplest content of the real, the affirming through self-negation should be discovered as an inner determination carried, *in a highly mediated form*, by human transformative action itself. Thus, upon its *analytical* discovery, the movement of contradiction must be ideally reproduced in its *synthetic* self-development through the *full sequence* of diverse qualitative forms it assumes until returning back to the singularity of the concrete conscious human action that initially triggered the investigation, i.e. the revolutionary action of the working class. Strictly speaking, then, at stake here is not the discovery of an ideal metaphysical abstraction called 'matter' which would constitute the common generic 'substance' that makes up all that exists. Instead, the point is to uncover the *immanent materiality, or simplest inner material content, of human 'critical-revolutionary' practice*. In

---

this sense, although Alfred Schmidt (1971, pp. 34–5) is right to point out against *Diamat* that 'matter' always exists in definite concrete forms and cannot be taken dogmatically or metaphysically as an all-embracing universal or ontological first principle from which we can explain the world, he is wrong to conclude that human beings cannot objectively cognise the simplest or most abstract mode of existence of the real as the pure movement of affirmation through self-negation, which is what one could call 'matter as such' (Iñigo Carrera 2008, p. 259). For a 'stylised' and concise presentation of the most relevant mediations involved in the two-way process of analytic discovery and synthetic unfolding of the movement of contradiction, see Iñigo Carrera 2008, pp. 256 ff.

[14] An attentive reader should have already realised that the champion of that inversion is *Diamat* (see Chapter 2, footnote 53 above). By transforming dialectics into logic, *Diamat unmediatedly applied* its *logical representation* of the more abstract determinations of matter into its more concrete forms of existence. This instead of reproducing in thought the way in which the abstract forms of matter self-develop into more concrete forms precisely by *qualitatively transforming* (*hence negating*) themselves, i.e. *by a process involving several mediations*. Hence *Diamat's* crude objectivism and naturalisation of the social world, which dissolved the specificity of the transformative powers of human productive subjectivity and action in the name of metaphysically conceived 'dialectical laws of matter'. Yet the critique of this vulgar materialism should not take the form, as happens with most Western Marxist currents, of a severing of the link between natural and social forms. This abstract radical separation between nature and society results from postulating that contradiction, the affirming through self-negation or self-movement at most only belongs to the human world, and that to claim otherwise necessarily leads to downplaying the active role of the human subject in the making of history (Colletti 1973; Lukács 1971; Schmidt 1971; Sartre 2004). This is the ground on which these authors take issue with Engels's project of a 'dialectics of nature'. Here it should be also noted that the question of whether the movement of contradiction constitutes a generic determination of both natural and social forms differs from that of whether Engels's own views on the matter are unproblematic, which I think in many respects they are. Now, as Veraza Urtuzuástegui (1997) convincingly shows, although there is no doubt that the idea of a 'dialectics of nature' *as understood by Diamat* certainly played the ideological part of reserving the role of conscious subject of history to the 'party-state' in order to suppress the struggles of workers, those reactionary

> Just as by dint of abstraction we have transformed everything into a logical category, so one has only to make an abstraction of every characteristic distinctive of different movements to attain movement in its abstract condition – purely formal movement, the purely logical formula of movement. If one finds in logical categories the substance of all things, one imagines one has found in the logical formula of movement the *absolute method*, which not only explains all things, but also implies the movement of things … All things being reduced to a logical category, and every movement, every act of production, to method, it follows naturally that every aggregate of products and production, of objects and of movement, can be reduced to a form of applied metaphysics. What Hegel has done for religion, law, etc., M. Proudhon seeks to do for political economy.[15]

In this idealist reduction of concrete movements to the logical form of movement, the transitions and relations between forms are justified by recourse to the logical necessity of the abstract form of movement, thus replacing the specific real necessity with general ideal ones. From its determination as the reproduction in thought of the real movement of things, method becomes, firstly, transformed into logic. Secondly, if one is to be consistent to eliminate the exteriority between form and content of knowledge, method becomes hypostatised as the force which bestows movement upon things (as, according to Marx, happened with Hegel).

---

implications do not necessarily follow from the way in which Engels himself approached the question or, more importantly, from the idea of a 'dialectics of nature' as such. As a matter of fact, the rejection of the existence of the movement of contradiction – hence of internal relations – among purely natural forms of reality actually leads to quite embarrassing results. In the first place, it implies accepting capital-determined forms of natural-scientific knowledge (based as they are on logical representation and external relations) as the eternal mode of human cognition of nature. In other words, it entails postulating a form of social consciousness (natural science) which would not be an expression of social being (capital), unlike every other social form, which would be seen as historically determined. Secondly, it deprives the very specificity of the conscious human subject that it purports to extol of any material foundation in the movement of nature. Far from 'empowering' human subjectivity and its transformative action, this denial of its emergence out of the movement of contradiction of natural forms renders it a purely idealistic construct, which can only be grounded on an abstract freedom of the individual. Whereas *Diamat* postulates an abstract and unmediated unity between the movement of nature and that of history, its Western Marxist critics end up positing an abstract difference. They are just the mirror image of each other.

[15] Marx 1976b, pp. 163–4.

But this is not all. In a sense, here Marx seems to be just repeating the critique of logical representation I have already discussed. And yet I think that this further formulation throws new light on the methodological question. First, because, as I have shown above, these passages make clear the all-important centrality of both Marx's insight that dialectical cognition consists in the ideal reproduction of the real movement of contradiction *and* his awareness of the risks of transforming the latter into another logical principle. This awareness, and the difficulties involved in their avoidance, would accompany Marx throughout the rest of his intellectual development of the critique of political economy. This is revealed, I think, by the explicit (albeit occasional) remarks he made about it, the reworking to which he subjected the crucial chapter one of *Capital*, and his eventual refraining from the publication of some pages with a summary of the general form of his method.[16] Furthermore, I think that Marx had no doubts about the source of the risk of relapsing into a logical representation. Namely, the reduction of the dialectical method to the formal way in which one deals with the *theoretical categories* through which representational science grasps real forms or, alternatively, which the dialectical logician constructs in the manner of representational thinking. In the case of Hegel, this was not really a problem, since he self-consciously considered that dialectical cognition should tackle the movement of pure thought forms as the prelude and source of movement of natural and social forms. But in the case of Proudhon, who attempted to develop a materialist account of the genesis and movement of economic forms of bourgeois society, it turned out to be quite problematic and actually led him to the most absurd contradictions and, eventually, to the most idealist of inversions.

> Economic categories are only the theoretical expressions, the abstractions of the social relations of production, M. Proudhon, holding this upside down like a true philosopher, sees in actual relations nothing but the incarnation of the principles, of these categories, which were slumbering – so M. Proudhon the philosopher tells us – in the bosom of the 'impersonal reason of humanity'.[17]

The central objection that Marx is raising against Proudhon is that he deals not with the forms of capital themselves – i.e. 'the social relations of production' – but with the 'economic categories' through which political economy represents them – i.e. 'the theoretical expressions'. Interestingly, as I have already pointed out in a previous chapter, that was precisely the methodological limitation of the *Paris Manuscripts*. But here Marx is unambiguous about the lesson he had drawn from those shortcomings of the 1844 text. The dialectical critique of political economy could not take the categories of political economy as ready-made, given presuppositions to constitute the starting point of an investigation. In other words, the critique of political economy does not consist in an allegedly more sophisticated logical treatment of categories, definitions, and so on, found in previous theories, the greater sophistication springing from the use of a dialectical logic instead of a traditional one. Quite to the contrary, it entails the confrontation of economic forms by oneself in order to provide a new ideal reproduction of the determinations immanent in them with the purpose of consciously acting upon them and thereby effecting their transformation.[18] I think that the crucial point Marx is getting at is exactly the same as the one made many years later in his last economic writing, the *Notes on Adolph Wagner's 'Lehrbuch der politischen Ökonomie'*.

---

[17] Marx 1976b, p. 165.

---

[18] Needless to say, this does not exclude the critical study of other authors as part of the process of tracing out the inner connections between economic forms, as a question of self-clarification in the process of inquiry. But our point is that the aim guiding the dialectical investigation of bourgeois economic forms is not the solution of the antinomies of the science of economics (Cf. Althusser and Balibar 1968), but the production of a novel science, the critique of political economy, which, *additionally*, 'solves' the scientific questions left unresolved by the former. The so-called 'transformation problem' is a typical case in point. With respect to this question, Marx did not try to solve the theoretical conundrum of classical political economy, namely, the relation between 'value' and 'price'. In the same vein, the problem for contemporary critics of political economy is not to prove that Marx was right, or to correct him by providing an alternative, 'logically consistent' solution to the 'theoretical problem' of the relation between value and price. The point is to develop the totality of the determinations of the forms of capital as the alienated subject of social life in order to find our revolutionary action as the necessary form in which capital produces its own annihilation. In this process we would certainly find that the law regulating the exchange of commodities, when seen in their most abstract determination as simple products of (privately performed) labour, negates itself as such when their most concrete determination as products of capital is discovered and followed into its further concrete forms. This would reveal that the law regulating the exchange of commodities takes on, as its own immanent necessity, a different concrete form when the latter is discovered in its concrete existence as an exchange of products of equally valorised individual capitals (Iñigo Carrera 1995). That is, of individual capitals affirming their unity as aliquot parts of total social capital – as a *class* vis-à-vis the workers (Arthur 2002a; Iñigo Carrera 1995). As a necessary moment of its development, this process of dialectical cognition would lay bare the real relations between the value of commodities and its concrete form of existence as price of production beyond the antinomies at which political economy arrives through its representation of those relations. However, this would not be

> In the first place [*De prime abord*] I do not start out from 'concepts', hence I do not start out from the 'concept of value', and do not have to 'divide' these in any way. What I start out from is the simplest social form in which the labour-product is presented in contemporary society, and this is the '*commodity*'.[19]

In opposition to this standpoint, Proudhon did proceed from 'concepts' or 'categories', and therefore inevitably reduced the dialectic to another empty formal methodology, used to give the appearance of a dialectical movement to the former, in turn uncritically taken from the political economists. Marx's later judgement about Lasalle's similar attempt at expounding political economy in the manner of Hegel is perfectly applicable to Proudhon as well. That is, the latter did not realise either that 'it is one thing for a critique to take a science to the point at which it admits of a dialectical presentation, and quite another to apply an abstract, ready-made system of logic to vague presentiments of just such a system'.[20]

Now, before proceeding to the reconstruction of further aspects of the Marxian critique of Proudhon's 'applied metaphysics of political economy', it is worth taking a detour and probing deeper into the implications of some passages contained in these pages of *The Poverty of Philosophy*, where Marx, in the course of his critical observations on Proudhon's peculiarly crude 'dialectical' treatment of economic categories, offers some methodological remarks whose significance is broader, and actually sheds additional light on his critique of Hegel's *Logic* beyond the points made in the previous chapter. Also, this discussion will hopefully provide further clarification of the point just made that Marx does not start out from 'concepts' or 'categories'. In a nutshell, Marx hints at the argument that Hegel's hypostasis of logic (hence his idealism) involves two prior interrelated steps, which the systematic unfolding of logical categories presupposes. In the first place, Marx takes Hegel to task for taking a *thought*

---

the aim of that development, but, as it were, a secondary 'by-product'. As a 'theoretical problem', the so-called transformation of value into prices of production is a scholastic abstraction of representational science.

[19] Marx 1975b, p. 198.

[20] Marx 1983, p. 261.

form (that is, a purely *ideal or formal* abstraction) instead of a real concrete form of 'material or sensuous being' as the starting point of his 'systematic-dialectical' development. This somehow resonates with the earlier Feuerbach-inspired critique of the *Science of Logic* found in the 1844 *Manuscripts* and is not, strictly speaking, something new. Secondly, and here we encounter the actual novelty in these further critical comments on Hegel, Marx points out that an immediate source of such a flawed systematic beginning resides in the methodological procedure by which the former (and, more generally in Marx's view, metaphysics) arrives at the simplest logical 'categories' which are deemed as the 'essentialities of things'. The problem, Marx insinuates, is that Hegel substitutes an inherently idealist method of *abstraction* for a proper dialectical *analysis* of real material forms.

Abstraction vs. Analysis: From Hegel's Ideal Reproduction of the Ideal to Marx's Ideal Reproduction of the Material Concrete[21]

In order to make sense of Marx's rather incidental comments on Hegel in *The Poverty of Philosophy*, it is firstly necessary to contextualise them through a brief critical discussion of the beginning of the *Science of Logic*.

Hegel opens his book with the category of 'pure being' as thoroughly 'empty thinking'.[22] In other words, the *Logic* starts with being as a *thought form* or the *thought of being*. The profound meaning and broader significance of this peculiar point of departure in Hegel's philosophy has been the subject of numerous controversies among commentators, particularly with regard to the connection between this category of thought and 'real being'. However, few scholars have actually taken Hegel to task for beginning his systematic dialectic with a thought form. In order to do so, I shall start out by critically examining the methodological procedure that is presupposed by Hegel's discovery of 'pure being' as the simplest category that sets in motion the subsequent dialectical unfolding of logical forms.

Hegel's choice of categorial starting point and the procedure by which he arrives at it follow from his idea that true speculative philosophy must involve *presuppositionless thinking*.[23] The 'beginning', he states, 'must be an *absolute*, or what is synonymous here, an *abstract* beginning; and so it *may not presuppose anything*'.[24] 'Strictly speaking', he further argues in the *Encyclopaedia*, 'this requirement is fulfilled by the freedom that abstracts from everything, and grasps its pure abstraction, the simplicity of thinking'.[25] More concretely, the procedure through which one can arrive at this pure abstraction consists in casting aside any thought that entails a certain complexity or concreteness, that is, any thought whose content presupposes the existence of any other thought. At this juncture, one could, of course, object that such an elementary abstraction would not have been reached on properly scientific grounds, that is, that it would be the result of a purely formal procedure that does not guarantee that we have actually reflected the immanent life of the subject matter under consideration. In other words, this category would be a purely *formal abstraction* resulting from an act of subjective reflection that remains external to the object of cognition. Indeed, Hegel's retrospective discussion of the beginning of science in the section on the Absolute Idea speaks to this issue: the simplest category constituting the point of departure of his *Logic* is depicted as an 'abstract universal', which is said to be arrived at by *abstracting from* all determinacy.[26] In other words, pure being, as the category that sets in motion the (synthetic) movement of the *Logic*, is a category akin to those of the 'understanding' or 'representational thought', that is, one which only grasps objects one-sidedly in terms of their abstract self-identity.[27] In fact, as Carlson suggests, it could be said that it is actually the understanding that undertakes the act of abstraction and not speculative thought as such.[28] In this sense, Hegel saw the specificity of his 'absolute method' as essentially residing in the synthetic moment, that is, in the reconstitution of the unity of the different moments of the totality through a movement from its most abstract thought form (pure Being) to its most concrete (the Absolute Idea).[29] Thus, he did not seem to recognise anything specifically speculative in the procedure through which the simplest category is arrived at, that is, in the reverse movement from the concrete to the abstract which the synthetic phase of systematic science presupposes.

---

[21] This section draws heavily on Caligaris and Starosta (2014). I am grateful to my co-author for kindly agreeing for me to include material from our jointly written article in this chapter.

[22] Hegel 1999, p. 82.

[23] Houlgate 2005, pp. 29 ff.

Still, for Hegel, such a discussion of the nature of the act of abstracting is immaterial at the initial stage of the investigation, since, strictly speaking, science proper has not actually begun. As he puts it some pages later in the *Logic*, '[w]hen being is taken in this simplicity and immediacy, the recollection that it is the result of complete abstraction … is left behind, outside the science'.[30] A Hegel scholar puts it nicely and helps clarify the point. In order to remain firmly on the path to a science without presuppositions, 'we must even abstract from and set aside – indeed deliberately forget – the very fact that pure being is the product of abstraction'.[31] Indeed, *once the standpoint of 'absolute knowing' is adopted*, and therefore *thought* as such is taken to be the legitimate immediate object of the investigation, the scientifically poor nature of the procedure through which its simplest category has been grasped (that is, the relative poverty of formal abstraction) does not compromise the validity of the subsequent dialectical unfolding that 'pure Being' sets in motion. Thus, regardless of the procedure used, the essential point is that in this process the speculative thinker has never abandoned her/his 'object realm', namely, pure thought. In this sense, as long as (some version of) the identity of thought and being reached in the *Phenomenology of Spirit* is taken on board, Hegel's argument is perfectly coherent on this score, although, as I argue below, it is inherently tied to his idealism.

However, matters are very different from a materialist standpoint. From this perspective, the method of formal abstraction as the prelude to synthetic development is rather problematic. In effect, when the immediate object of the act of cognition is not thought but an existing form of 'material being', the formal abstraction resulting from arbitrarily casting aside all specific determinations inevitably takes us rather far from, and actually outside, the very 'object realm' that we originally set about to cognise, namely, material reality. Here we can finally get at the gist of Marx's critique of Hegel's and the metaphysicians' methodological procedure in *The Poverty of Philosophy*, which he sarcastically presents through the example of the idealist reduction of a house to a logical category. As Marx puts it, if we abstract from the materials which make up a house, the result will be a purely ideal representation of a house with no materials, something which has no real referent, since there is no such thing in material reality.[32] Hence, in abstracting from particular features of a concrete material object (a procedure that can be repeated as many times as the thinker wishes in order to find an ever simpler or more universal determination), we will no longer be dealing with really existing objects, but with *purely*

---

[30] Hegel 1999, p. 99.

[31] Houlgate 2005, p. 87.

[32] Marx 1976b, p. 163.

ideal or formal abstractions, that is, with 'pure thoughts'. On this basis, the subsequent reconstitution of the unity of the object cannot but result in a purely ideal construct, which will remain external to the object of cognition that constituted the starting point, and which only by chance will reproduce in thought 'the immanent life of the subject matter'. It follows from this that, for a materialist, the consequence of using the method of formal abstraction is, if she/he does not wish to become a Hegelian idealist, the relapse into Kantian dualism, where the theoretical construct, no matter how internally consistent or coherent, will inevitably be radically separated from the real object of cognition.

This is why a materialist engagement with Hegel's *Logic* cannot avoid the critique of the method of absolute formal abstraction that sets into motion the whole systematic development, a question which is not often addressed by commentators. Thus, in criticising Proudhon, Marx takes the opportunity to take stock with this aspect of Hegel's thought. In fact, this was precisely the cornerstone of Feuerbach's foundational critique of Hegel, as the following passage from *Principles of the Philosophy of the Future* eloquently puts it. Hegelian philosophy, Feuerbach states,

> … presupposes nothing; this is nothing more than to say that it abstracts from all objects given immediately … In short, it abstracts from everything from which it is possible to abstract without stopping to think, and makes this act of abstraction from all objectivity the beginning of itself.[33]

In part, Marx would develop, in *The Poverty of Philosophy*, the critique of Hegel's idealist abstraction along clearly Feuerbachian lines:

> Is it surprising that everything, in the final abstraction – for we have here an abstraction, and not an analysis – presents itself as a logical category? … If we abstract thus from every subject all the alleged accidents, animate or inanimate, men or things, we are right in saying that in the final abstraction, the only substance left is the logical category. Thus the metaphysicians who, *in making these abstractions, think they are making analyses* … are right in saying that things here below are embroideries of which the logical categories constitute the canvas.[34]

---

[33] Feuerbach 1986, p. 19.

[34] Marx 1976b, p. 163, my emphasis.

The methodological significance of the latter passage for the purpose of my argument is broader and goes beyond a rehearsal of Feuerbach's earlier critique. More importantly, the text brings to light what Marx mentions as the alternative to Hegel's procedure of formal abstraction, namely, *analysis*. Unfortunately, despite the stark contrast between abstraction and analysis made in the text above, Marx does not probe into the issue any further. Moreover, despite the many occasions on which he highlights the important role of analysis as a necessary moment of his scientific method,[35] there is no place in his works where he fleshes out in any detail the *specific form* of the analytical process within his materialist dialectical method.

Now, although Marx did not leave us any written formalisation of the specificity of materialist analysis, we shall see in the next chapter that it is possible to grasp its concrete workings from the 'analysis of the commodity' contained in the opening pages of *Capital*. For the moment, it suffices to note that, as is now widely acknowledged in the literature, the sequence at that particular stage of Marx's argument consists in going from *form* to *content*. However, the crux of the matter does not simply reside in realising this (which, at any rate, is explicitly announced by Marx himself in those pages), but in grasping the precise way in which properly dialectical analysis discovers the content behind the form and, therefore, their inner connection. In order to discuss this crucial point, we need momentarily to stray away from Marx's critique of Proudhon.

It is here where we can appreciate the relevance of Iñigo Carrera's contribution to the contemporary debate on Marx's dialectical method. For in his work he not only throws light on the *synthetic* moment of the dialectical investigation (i.e. the movement from the abstract, or content, to the concrete, or form), as do most authors in the 'systematic dialectics' readings of *Capital*; he also puts particular emphasis on the formalisation of the specifically dialectical form of the phase of analysis in Marx's method (the reverse sequence from the concrete to abstract). Moreover, he shows that the two stages constitute an indissoluble unity in materialist dialectics, so that a proper grasp of the first analytical phase is the condition for a successful unfolding of the synthetic phase of reproduction proper.

As Iñigo Carrera points out,[36] conventional scientific method analyses a concrete form by separating what repeats itself from what does not in order to arrive at a certain characteristic. In turn, this common attribute makes possible the mental construction of a definition of that concrete form as that which has this or that attribute. On his part, I have shown how Hegel's pure abstraction in the *Logic* proceeds by casting aside all particular features of objects (that is, all determinacy) in order to find through that one step the 'abstract universal' that constitutes its simplest element. Regardless of their differences, these two procedures have in common that they result in strictly mental abstractions or categories which, by their own nature as 'pure thoughts', cannot but remain external and alien to real forms of material reality. Conversely, dialectical thought analyses a concrete form, first of all, by facing it as embodying a qualitative potentiality for transformation, and second, by grasping that qualitative potentiality as the concrete form in which a more abstract form realises its own qualitative potentiality, that is, its real necessity. Thus the dialectical analytical appropriation of the universe of different real forms does not proceed through an identification of the distinctiveness of forms on the basis of the degree of repetition of certain attributes. But neither does it operate, like Hegel, by *abstracting from* every particular determination. Rather, it analytically separates the different forms by discovering as *immanent* in a particular concrete form the realised potentiality of another real form, which is abstract with respect to the first one, but concrete with respect to another form of which it is the realised potentiality.

---

[35] Marx 1989b, p. 500; and 1993, p. 100.

[36] Iñigo Carrera 2013.

It follows that while conventional scientific method grasps the general determination of real forms as immediate affirmations and hence self-subsistent entities, the distinctive mark of the process of analysis in dialectical research is to grasp, *in the same analytic movement*, both the concrete form under scrutiny and the more abstract one of which the former is the developed mode of existence. In other words, dialectical thought grasps each form as the affirmation through self-negation of another, more abstract one (hence, as subjects of their own movement). Moreover, in contradistinction to Hegelian abstraction or conventional scientific analysis, Marx's dialectical analysis at no point leaves the terrain of the real. Both the immediate concrete form that he encounters and the relatively more abstract one discovered through analysis (the content) are wholly objective and real determinations of the object under scrutiny. In particular, it is important to highlight that the more abstract form is discovered *within* the immediate concrete form that constitutes the starting point. The content is thus immanent in the form as its mode of existence. This analytical procedure must be then renewed for those other more abstract forms, but now treated as the real concrete whose inner content the research is trying to uncover. Only once all those inner form determinations have been discovered through analysis should the investigation undertake the 'return journey' through which those abstract determinations, now in their self-movement, lead to 'the reproduction of the concrete by means of thought'.[37]

Now, this materialist intellectual reproduction of the concrete not only differs from Hegel's idealist systematic dialectics by virtue of its distinctive starting point with a real determinate form of 'material being' as the object of *dialectical analysis* (as opposed to the purely ideal concepts or categories resulting from Hegel's formal abstraction or representational analysis). Furthermore, and actually as a consequence of this, it leads to a different formal structure of the synthetic phase of reproduction, a point which is also picked up on by Marx in his methodological critical observations on metaphysics in *The Poverty of Philosophy*. Let us therefore elaborate further on this point, through an examination of the general form taken by Hegel's systematic unfolding of categories.

Towards the end of the *Logic*, Hegel discusses this question explicitly. 'What is to be considered here as method', he states, 'is only the movement of the *Notion* itself … the *universal absolute activity*'.[38] However, this movement is not presented by Hegel as simply taking the generic form of affirmation through self-negation through which a self-determining subject realises its own immanent necessity. Instead, insofar as he conceives of it as a pure movement of thought striving for a fully developed mode of expressing its truth content, he presents it as the unity of the *three moments* through which thought needs to pass in order to self-posit in such an adequate shape. Thus, he concludes, 'the whole form of the method is a triplicity'.[39] The movement of affirmation through self-negation, which, as the simplest content of the 'immanent life' of any material object, constitutes the generic form taken by a materialist dialectical unfolding, is represented by Hegel as the abstract sequence of an affirmation, a negation and, lastly, the negation of the negation. In other words, Hegel does not directly present the third moment, which is the only one that constitutes the effective material reality of the object. Instead, he firstly needs to posit the prior two 'imperfect' moments, which are just formal stages through which thought needs to go to grasp the 'truth' of the object, as if they were constitutive of the effective objective reality of the object itself. This 'triadic structure' of the absolute method, which derives from the idealist character of the Hegelian dialectic, is also eloquently and sarcastically criticised by Marx in *The Poverty of Philosophy*:

---

[37] Marx 1993, p. 100.

[38] Hegel 1999, p. 826.

[39] Hegel 1999, p. 836.

> So what is this absolute method? The abstraction of movement. What is the abstraction of movement? Movement in abstract condition. What is movement in abstract condition? The purely logical formula of movement or the movement of pure reason. Wherein does the movement of pure reason consist? In posing itself, opposing itself, composing itself; in formulating itself as thesis, antithesis, synthesis; or, yet, in affirming itself, negating itself, and negating its negation.[40]

In brief, what is rational in Hegel's dialectic, that is, its method of immanent self-development of the life of the subject matter, appears inverted under the mystical form of the three moments of self-developing pure thought. Again, this mystical shell directly stems from the fact that Hegel's systematic dialectic does not ideally follow the immanent life of a concrete material object but an ideal one, namely, pure thought. Hegel's 'mysticism' in the *Logic* therefore derives from being the *ideal reproduction of the ideal*. By contrast, in engaging in analysis instead of abstraction, Marx's scientific method at no point leaves the concrete material object of investigation behind. No matter how abstract and far removed from its immediate sensuous existence the analytical process eventually takes him, *he remains firmly within the materiality of the object*. As a consequence, the moment of systematic synthetic unfolding cannot but be the 'reproduction of the concrete by means of thought'.

Marx's Movement of Contradiction beyond Proudhon's *Representational* 'Unity of Opposites'

In addition to the previous aspect of Marx's critique of *dialectical logic* discussed above, which, as it were, dealt with the 'logical' part of the expression, there is in *The Poverty of Philosophy* another crucial dimension of the question related to the 'dialectical' part. Whilst the first part has been occasionally highlighted by the most elaborated commentaries on Marx's scientific method,[41] the latter has been generally overlooked.[42] I am referring to the transformation that the real movement of contradiction suffers when *represented* through a *dialectical logic*. In the case of those forms of representational thinking that structure themselves following a traditional formal logic, the problem does not even arise. That is, since they start by excluding the contradictory character of reality as the elemental rule guiding their representations, the conscious attempt to ideally appropriate its movement does not even form part of their agenda. The case of those forms of thought explicitly accepting the reality of contradiction, and which therefore try to grasp its movement, is quite different. And it is this perspective of which Proudhon is a case in point. For what he attempted to develop is precisely the 'system of economic contradictions'. Yet I would like to argue that the relevance of Marx's critique of this aspect of Proudhon's thought goes beyond this specific author. For the claim that the superiority of dialectics consists in its ability to deal conceptually with the contradictory nature of reality (natural and social for some, only social for others) has been a trademark of most currents of Marxist thought since its inception. The question is what do these authors understand by reality being 'contradictory'. And the point I want to make is that Marx's critique of Proudhon throws light on the way in which, when dialectic is reduced to a form of logic, contradiction and its movement are grasped through a *representation* of them. According to Marx's critique of Proudhon's 'metaphysics of political economy', in what does the representation of the movement of contradiction by

---

[40] Marx 1976b, p. 164.

[41] The works by Murray (1988) and Meikle (1985) are perhaps the most sophisticated in this respect, although I part company with the idiosyncratic conclusions developed by them from that correct initial insight about Marx's rejection of formalistic methodologies. For instance, I cannot agree that what follows from that insight is the conception of Marx's novel mode of scientific knowledge as involving a new relation between science and *morality* (Murray), or as involving a *philosophy* that prioritises ontology over epistemology (Meikle). Marx's revolution in the mode of cognition transcends both morality and philo-

---

sophy in all of its forms. Still, among its merits Meikle makes a crucial point rarely found among Marxists, namely, that in Marx there is no such a thing as 'dialectical logic'. See especially Meikle 1979. Precisely for this reason, and in spite of its otherwise thought-provoking quality, I find unsatisfactory much of the recent literature on the dialectical method coming from that broad current within Marxism grouped under the name 'new or systematic dialectics', which makes use of Hegel's *Logic* to make sense of the dialectical exposition in *Capital* (for a useful overview, see Kincaid 2008). Despite their own recognition of the inseparability of content and form of knowledge, one could argue that many of these authors run precisely the risk I have highlighted of turning the dialectical method into a general logic to be applied to an external content. See, among others, Reuten and Williams 1989; Tony Smith 1990a and 1993; Uchida 1988 – although not formally associated with the others – and, from the Uno School, Albritton 1999 and Sekine 1997. Supporters of the 'homology thesis' like Arthur (2002b) in a way avoid this shortcoming, but only at the cost of the adoption of a highly contentious idea about the strict isomorphism between Capital and the Idea.

[42] This is another key methodological insight to be found in the work of Iñigo Carrera (1992 and 2008).

dialectical logic consist? In order to answer this question, let us take a look at the way in which Marx characterises Proudhon's depiction of contradiction.

> Let us see now to what modifications M. Proudhon subjects Hegel's dialectics when he applies it to political economy.
>
> For him, M. Proudhon, every economic category has two sides – one good, the other bad. He looks upon these categories as the petty bourgeois looks upon the great men of history: *Napoleon* was a great man; he did a lot of good; he also did a lot of harm.
>
> The *good side* and the *bad side*, the *advantages* and *drawbacks*, taken together form for M. Proudhon the *contradiction* in every economic category.
>
> The problem to be solved: to keep the good side, while eliminating the bad.[43]

If we set aside the specificities of Proudhon's particularly crude conception, consisting in the mere enunciation of a good side and a bad side in each economic category, we can reach a more general point regarding the representation of contradiction by dialectical logic. In a nutshell, the latter grasps the contradictory nature of things as consisting in being the *unity or interpenetration of opposites*.[44] In this sense, it claims to go beyond formal logic since it accepts that the real determinations of things cannot be grasped through a single attribute since they are the embodiment of antithetical determinations. But does it? In other words, is it in this form that we can appropriate in thought the inner life of the subject matter at stake, overcoming the appearance of externality through which the relation between real forms presents itself? In order to answer this question, let us recall the objective basis for the appearance of externality between real forms.

---

[43] Marx 1976b, p. 167.

[44] Note that the key issue at stake is not terminological (i.e. whether Marx actually used the expression 'unity of opposites', which might have been occasionally the case), but revolves around the specific meaning attributed to the term. Thus, abstractly considered there is nothing wrong about referring to the contradictory nature of the real as involving a 'unity of opposites', as long as it is made clear that what matters is the *movement* that gives unity to those 'opposites', through which one becomes determined as the concrete mode of existence of the other, more abstract form. However, given the widespread association of the expression with the kind of representational perspective criticised in this section, I think it is sensible to refrain from using the term altogether.

In its immediate manifestation, reality appears as a universe of unconnected real forms. In this sense, every real form appears as a self-subsistent entity, and the realisation of its determination as an immediate affirmation. This appearance is not a subjective misconception but the necessary form in which the inner connections between real forms appear when the process of determination is externally grasped in its immediacy, as already realised. That is, when we obviate the mediations that make a real form a concrete mode of existence of the necessity of another, more abstract form. Since, as Marx stated regarding the relation between commodities and money, 'the intermediate steps of the process vanish in the result and leave no trace behind',[45] the objective illusion arises that 'those intermediate steps' do not exist at all. Hence, real forms of different degrees of concreteness appear as co-existing side by side without any real necessity linking them in a determinate fashion. In brief, the representation of the world through formal logic grasps the *movement* of affirmation through self-negation that constitutes the determination of real forms only in its result, sticking to the appearance of externality between an abstract form and its necessary concrete mode of existence.[46]

Now, the following question arises. Does the representation of real forms as a unity of opposites characteristic of dialectical logic overcome that manifestation of exteriority between them? It is my claim that it does not. For the difference between dialectical logic and formal logic actually comes down to the fact that the former does not represent real forms as isolated entities, but always finds each of them as 'necessarily' associated with another one which, it claims, is its 'contrary'. However, this does not mean that the indifference between them has disappeared. Because the fact that each form is represented as coexistent with its opposite does not change the fact that each real form still continues to be seen as an *immediate* affirmation and so does their unity. But the *specific movement* that *mediates* the existence of 'all that exists on land or under water', and which constitutes the immanent connection between different real forms, continues to be beyond the comprehension of this alternative form of logical representation. The unity that is thereby grasped continues to be completely extrinsic. It is *a unity between two opposing immediate affirmations* which, at most, 'interpenetrate in a relation of struggle'.[47] But each of the poles of that unity does not carry within itself the necessity of its own self-transformation. That is why, again, movement is not seen as the immanent necessity characterising every real form, but needs to be insufflated by the ideal necessity of logic. Hence, it is only the subjective reflection of the dialectical logician that leaps from one pole to the other generating only the 'shadow of movement' which pushes cognition forward. As much as formal logic, dialectical logic is therefore impotent to reproduce the real movement in thought and represents real forms as motionless abstractions.

---

[45] Marx 1976g, p. 187.

[46] Iñigo Carrera 2008, pp. 279–80.

[47] The *locus classicus* of this latter formulation is the work of Mao (2007) who, despite the occasional reference (or rather 'lip service') to self-movement (2007, pp. 69–70), is unable to grasp the affirmation through self-negation of real forms. Mao himself was basically rehearsing the earlier remarks of Lenin in his *Philosophical Notebooks* (1961), and of

It is important to emphasise that I am not rooting for the replacement of one absolute logical principle (unity of opposites) with another, allegedly superior one (affirmation through self-negation). And yet I am aware that, confined to this abstract level, my discussion might give the false impression that this is the case. But my point is just that when cognition fails to reproduce in thought the *specific* necessity for self-negation immanent in a determinate real form, it inevitably ends up representing the former movement as a unity of opposites. Hence, in order to demonstrate this point fully, the general discussion of how dialectical logic represents the movement of contradiction through the unity of opposites remains insufficient. I should therefore proceed by showing concretely how this inversion takes place in the case of the determinations of a specific concrete form. However, that is not the path that I shall follow in the rest of this chapter. The reason for this is that a satisfactory way of addressing the question would require that I run too far ahead in the main argument of this book concerning Marx's discovery of the determinations of revolutionary subjectivity. I shall therefore deal with that issue in the following chapters, in

---

Engels's unfortunate codification of the 'unity of opposites' as one of the three 'fundamental laws of dialectics' in the *Dialectics of Nature* (Engels 1987, pp. 357, 492–8). This is not the place to assess Engels's own views on the dialectical method, even less so to address the thorny issue of the extent to which his views coincided with those of Marx and/or whether they are the intellectual source of the vulgar materialism of *Diamat*. But it seems to me an uncontroversial point that there are a number of formulations in Engels's work in which he did tend to confuse affirming through self-negation with the unity of opposites. To begin with, he makes *reciprocal action* and the 'universal interconnection of everything' the central notion of his dialectics of nature (Engels 1987, pp. 511–12). See Veraza Urtuzuástegui 1997, for an excellent balanced commentary on this aspect of Engels's dialectics of nature. But this is also clear from the allegedly unorthodox formulation of the connection between economic and political forms of capitalist social relations in the oft-quoted 1890 letter to J. Bloch, in which he posits that the movement of society is a matter of 'the *interaction* of all these elements' (Engels 2001, p. 35). Clearly, he does not say that the movement of contradiction is a matter of *economic content and its self-negating political form of existence*.

which I will illustrate this critique of dialectical logic by looking at the different social forms taken by the modern alienated social subject. Moreover, and in order to show the political nature of what at first sight might seem a purely scholastic question, I shall also deal with the relevance of all this for the comprehension of the social determinations of the revolutionary consciousness of the proletariat.

I prefer, for the moment, to leave the discussion at this abstract level and move on with my reconstruction of the way Marx advanced in his revolution in the mode of scientific cognition. And I think that the next crucial step Marx made in that direction through the criticism of Proudhon was in making explicit the practical character of a truly dialectical critique. That is, in discussing the question of workers' strikes and combinations, Marx showed very clearly that the new science that he was in the process of developing was of an eminently political nature. In short, what was at stake in his investigation was the conscious organisation, i.e. the discovery of the social necessity, of the political action of the working class.

Marx on Proudhon II: Dialectical Knowledge and Political Action

In the previous section, I dealt with the methodological significance of Marx's critique of Proudhon as a critique of dialectical logic from the perspective of a materialist dialectical *method*. However, I have already mentioned that this engagement with Proudhonian socialism entailed other aspects that I regard as crucial in the development of Marx's thought. I find these additional aspects, which also pertain to the specific mode of Marx's scientific thinking, and which expose without ambiguity the inherently political character of the methodological question, synthesised in Marx's discussion of workers' strikes and combinations. This question, together with Marx's insights on the adequate way of tackling it, illustrates very clearly the distinctive features of dialectical scientific thought as practical criticism. On the other hand, we shall see that Marx's own treatment of the question at that time was rather rudimentary and, in this sense, unsatisfactory as a way of displaying the plenitude of the critical and revolutionary powers of the critique of political economy. And yet I will show that those very limitations of Marx's scientific development also prove to be illuminating (albeit in a negative way) of the immediately practical nature of science in its dialectical form. Moreover, those limitations also provide an indication of the direction in which Marx's thought would subsequently take. That is, one can read the incompleteness of Marx's critique of political economy as programmatic for his mature works.

What triggered Marx's polemic against Proudhon was the latter's 'political indifferentism' concerning industrial action over wages and revolutionary action in general. Regarding the former, and as an expression of his economic analysis, which denied the practical operation of the determination of value by labour time in capitalist society, Proudhon saw it as completely useless. This is because he concluded that the only result of an increase in the nominal wage would be an increase in the price of the means of subsistence of the labourers, thereby leaving the real wage (i.e. the conditions of reproduction of the workers) intact. Regarding revolutionary action aimed at obtaining 'political supremacy', Proudhon rejected it too, preferring 'to burn property by a slow fire, rather than give it new strength by making a St Bartholomew's Night of the property owners'.[48] For him, the most potent form of political activity available to workers was not their revolutionary action upon the alienated forms of their social being in order to effect their transformation in the direction of their self-annihilation. According to Proudhon, those social forms should be left alone. Instead, the energies of the workers had to concentrate on building the alternative socialist schemes devised by socialist theoreticians. Hence Marx's sarcastic comment that 'the Socialists want the workers to leave the old society alone, the better to be able to enter the new society which they have prepared for them with so much foresight'.[49] That is, Marx criticised Proudhon for thinking that workers could escape their general social relation and implement alternative socialist schemes of mutual aid in the 'interstices' of this society. The abolition of capital would then be the result of the slow but progressive spread of these schemes 'by example'.[50]

The aim guiding Marx's polemic was, therefore, the nature of the political action of the working class. The question at stake was the provision of scientific grounds for his political position concerning the content and form of proletarian action antagonistic to capital. In other words, what this controversy shows is that for Marx the starting point of his scientific development was not an abstractly theoretical discussion of economic categories (for instance, the wage), but the transformative action of the working class. Thus, this specific controversy exposes a more general feature of the dialectical method. Namely, what sets into motion the dialectical investigation is the answer to the question of the form that we must give our transformative action in order to 'change the world'. As practical criticism, science thereby consists in giving that transformative action a fully conscious form. This means that what draws our attention to a particular concrete form is not an abstract desire for knowledge. If we face a concrete form of reality as an object of scientific cognition, it is because it can affect us when realising its own determinations, or, more importantly, because we can realise the potentialities it embodies through the actualisation of the potentialities of our action. The discovery of the relation between those two potencies in the totality of its determinations (i.e. the real necessity of transformative action beyond any appearance) is the generic aim of dialectical cognition.[51] To transform or to be transformed; that is the question.

---

[48] Cited in McLellan 1973, p. 160.

[49] Marx 1976b, p. 210.

[50] Shortall 1994, p. 36. One could argue that there is a striking similarity between the Proudhonian understanding of the abolition of capital and the Autonomist Marxist view – widespread among some social movements associated with, for example, 'Social Centres' in Italy in the 1990s – that revolutionary activity is about the micro or molecular politics of experimental construction of 'autonomous spaces of freedom' (Negri and Guattari 1999, pp. 73–80; Krasivyj 1996; Wright 1995/6). Or, alternatively, about 'exodus' from capital, i.e. from the alienated *general* social relation of present-day society (see Virno 1996).

In the concrete case Marx was facing, the relevance of the first concrete form at stake in the discussion with Proudhon (the wage form) was almost self-evident. That is, even a superficial observation of the movement of wages revealed the way in which it could affect (i.e. transform) the social existence of the workers. The question to answer was, therefore, what is to be consciously done in relation to wages? What form should workers give to their action to transform a determinate concrete form they were facing (to begin with, the quantitative transformation of the wage)? Should they struggle? Should they co-operate in that struggle, i.e. organise themselves? Or should they refrain from political action, and harmoniously and unconditionally submit their will to that of the capitalist, since wages are not determined by their political action or the will of the capitalist, but through the operation of the laws of political economy? Or should they not combine, since at any rate any real rise in wages eventually dissolves as an effect of a correspondent increase in prices? Furthermore, assuming that they definitely need to form combinations, should their conscious association stop at the level of an individual capitalist firm or at the level of a branch of production? Or should the struggle against the capitalists become general and, therefore, take the form of a *class action and, therefore, a general political action*? The need to tackle these questions in a fully conscious manner (i.e. dialectically) is evidenced by the reactionary political conclusions that emerge when they are addressed by a form of scientific consciousness, such as that of economists and utopian socialists, which stops at the immediate appearances of real relations. In particular, the appearance of externality between the laws that regulate the 'regular process of industry' and the struggles of workers through the formation of 'combinations'.

---

[51] Iñigo Carrera 1992.

According to the economists, wages are determined by the eternal laws of political economy and, among them, by its most sacred, i.e. the law of supply and demand. Moreover, combinations breach the main condition under which those laws can harmoniously operate in their purity, i.e. 'competition', and therefore act as an external disruption of the otherwise smooth workings of the economic process, thus leading to crises, the introduction of machinery and a further reduction in wages. Hence, the economists conclude, workers' struggles are not only ridiculous but also dangerous for the preservation of their own living conditions.[52] Thus was the advice of the spokespersons of the bourgeoisie.

For his part, Proudhon followed the economists in their rejection of combination not only for its lack of actual influence on the real wage, but also for its impotence *substantially* to alter the form of social relations. No matter how much they struggle, Proudhon's argument went, 'workers will continue nonetheless to be workers, and the masters will continue to be masters, just as before'.[53] Hence, instead of futilely wasting their energies in organising their struggle against capitalists, workers should devote themselves to the peaceful implementation of fair utopias based on the eternal principles of human reason, leaving the movement of the wage to the unjust laws of political economy.

As stated above, Marx's reply to the objection to working class 'combinations' by both Proudhon and the economists shows at the same time the insights he was developing regarding the role of science as the conscious organisation of proletarian political action, and the limitations of his approach, given the preliminary status of his development of the critique of political economy at that time.

Regarding the former, it is interesting to note how Marx tackled the question by attempting to overcome the appearance of externality between 'the laws of political economy' (i.e. the movement of capital accumulation) and the political action of workers (i.e. the class struggle) through the conscious reproduction of the relevant determinations at stake. This involved, in the first place, the dialectical sensitivity to grasp the inner connection between what appeared to the ideological consciousness as absolute opposites, namely, competition and direct association, in the relation among workers. For the logical representation of both the economists and Proudhon, either one or the other operated in capitalist society. For the former, the atomistic relations of competition between commodity owners were the essence of the 'pure' laws of capital accumulation, whose smooth operation could not but be disrupted by what was a clear attempt to impose some sort of 'monopsonic' conditions in the sale of labour power. For his part, Proudhon agreed with the economists on the natural character of competition, since, as an 'economic category', it must be just another incarnation of the 'impersonal reason of humanity'. The problem resided, according to him, in the distorted way in which it operated in bourgeois society and which brings about the 'bad side' of competition. Far from attempting to negate, through their political action, the atomistic relations in which they find themselves, workers should try to recreate them but in pure form, through the implementation of alternative schemes 'outside' bourgeois society. The establishment of relations of direct solidarity between workers in their struggle over the wage was seen by Proudhon not only as being incapable of really affecting the level of wages, but also as playing no role in the radical transformation of bourgeois society.

---

[52] Marx 1976b, p. 209.

[53] Marx 1976b, p. 210.

Against these two views, Marx came up with the discovery that far from being absolute opposites, competition and association were necessary forms that the relations among workers took as concrete forms of the movement of their alienated general social relation, i.e. the accumulation of capital. That is why, 'in spite of both of them, in spite of manuals and utopias, combination has not yet ceased for an instant to go forward and grow with the development and growth of modern industry'.[54] In other words, Marx is highlighting that the relations of solidarity among workers are not the abstract negation of their competitive relations, but the concrete form in which the latter develop as a result of their own movement. On the one hand, competition is actually the most general social relation characteristic of the mercantile nature of bourgeois society, 'which is association founded on competition'.[55] On the other hand, inasmuch as it develops large-scale industry, it is the very result of the movement of competition to produce the necessity of its own negation, namely, 'combination'.

---

[54] Marx 1976b, p. 210.

[55] Marx 1976b, p. 194.

> Large-scale industry concentrates in one place a crowd of people unknown to one another. Competition divides their interests. But the maintenance of wages, this common interest which they have against their boss, unites them in a common thought of resistance – *combination*.[56]

Thus, the direct association between workers does not represent the *elimination* of relations of competition between commodity owners. It just polarises the latter into two antagonistic classes of commodity owners: capitalists and workers.

> Thus combination always has a double aim, that of stopping competition among the workers, so that they can carry on general competition with the capitalist. If the first aim of resistance was merely the maintenance of wages, combinations, at first isolated, constitute themselves into groups as the capitalists in their turn unite for the purpose of repression, and in the face of always united capital, the maintenance of the association becomes more necessary to them than that of wages.[57]

In brief, Marx is arguing that it is in the nature of the laws of motion of the present form of social being (and not a distortion of it) to engender the necessity of the collective political action of workers through the formation of associations. In this sense, workers cannot abstractly *choose* not to do it. As personifications of their alienated social being, they are *compelled* to associate by the very conditions in which they are reproduced and, as Marx continues, they will eventually and inevitably *expand the scope* and *transform the aim* of their association.[58] Furthermore, he makes clear that the objective potency to succeed in that struggle does not spring from the abstractly self-determining will of the proletariat, but rather arises from the objective determinations of the reproduction of the specifically capitalist social relations of production ('competition'). So much so that the result of its struggle eventually crystallises in the only form in which the general conditions of social reproduction can impose themselves as an alienated attribute of capital, namely, as a legal regulation by the capitalist state.

---

[56] Marx 1976b, p. 210.

[57] Marx 1976b, pp. 210–11.

[58] And yet, as we shall see in the second part of the book, the alienated social necessity to establish relations of solidarity in the sale of labour power, which the workers must personify, is mediated by their *apparently* free will.

> In England, combination is authorized by an Act of Parliament, and it is the economic system which has forced Parliament to grant this legal authorization. In 1825, when, under the Minister Huskisson, Parliament had to modify the law in order to bring it more and more into line with the conditions resulting from free competition, it had of necessity to abolish all laws forbidding combinations of workers. The more modern industry and competition develop, the more elements there are which call forth and strengthen combination, and as soon as combination becomes an economic fact, daily gaining in solidity, it is bound before long to become a legal fact.[59]

Thus far, I have reconstructed the way Marx replied to the objections of the economists and Proudhon to the collective industrial action of the workers. From the point of view of *method*, the important point to highlight is that the form of his reply was to develop (albeit in a rudimentary and insufficient way) the scientific consciousness of the real determinations of the workers' trade-union struggles so as to become aware of their *necessity*.

Now, even if necessary as a form of political action, the question remains as to whether trade-union struggle has any role to play in the overcoming of capitalist society. In this sense, it is important to remember that Proudhon's opposition to that form of political action not only came down to its futility regarding the quantitative movement of wages, but also, and more importantly, involved its rejection as a valid form of attempting to go beyond capital.

Again, one can see Marx's way of putting the question as being exemplary of the dialectical form of tackling any concrete form as an issue concerning the political action of the class. For although Marx grasped the social necessity of trade-union action, he also realised that it was limited in its *immediate* transformative power: in its simplest determination, it can only produce a quantitative change of the wage form, but not a substantial qualitative transformation of it, i.e. its abolition. Hence the need for workers' political action to transcend that limited form and Marx's subsequent 'phenomenology of class struggle' leading to the revolutionary conquest of political power in the rest of the text. However, Marx did not just extrinsically *counterpose* the different forms of political action of the proletariat, confining trade-union action to the realm of reformism, in turn seen as the abstract opposite of revolutionary action. As I mentioned above, dialectical cognition must provide the necessity of the transformative action of the workers in the *totality* of its determinations. And seen from a 'world-historical' perspective, the political action of the proletariat is the unity of its different necessary moments until it becomes produced as a fully conscious revolutionary action with the power to abolish capital through the construction of the free association of individuals.[60] In this sense, the struggle over wages and working conditions, along with the formation of trade unions as its adequate organisational form, is seen by Marx as one of those necessary moments in the historical production of the fully developed revolutionary subjectivity of the proletariat.[61] On the other hand, we shall see that it is precisely on that point that the insufficiency of Marx's positive development of the critique of political economy at that stage was more strongly felt. For, in actual fact, in this text Marx did not provide a dialectical exposition of all the determinations involved in the different forms of political action of the workers necessary for its production as fully conscious revolutionary action. Quite to the contrary, he offered no more than an impressionistic description of the concrete history of the workers' movement in England, which he extrapolated and generalised as *the* historical tendency of the working class as a whole.

---

[59] Marx 1976b, p. 209.

In all fairness to Marx, it is important to point out that his insights into the determinations of proletarian action went a little further. For, in relation to the particular case of trade-union action, Marx was already aware that its determinations were not exhausted in being an active force in the quantitative transformation of the wage form. As we can see from the following passage, the former's transformative power exceeded the mere quantitative change in the wage form:

---

[60] Thus the traditional opposition between reform and revolution misses the point. The common understanding of those two terms is the ideological representation of different moments of the progressive transformations of capitalism towards the free association of individuals personified by distinct forms of the political action of the working class, which emerges when we abstract those transitions from their concrete determinations. From a dialectical standpoint, what is always at stake is precisely the recognition of the necessity of a determinate form of political action as a concrete form in which capital develops and, therefore, moves towards its dissolution through the conscious revolutionary activity of the proletariat. This recognition involves the discovery of the concrete determinations of each form of political action, which would show their respective transformative power in its determinacy, that is, both in its potentiality and the limitations to that potentiality.

[61] Marx 1976b, pp. 210–12.

> In England, strikes have regularly given rise to the invention and application of new machines. Machines were, it may be said, the weapon employed by the capitalist to quell the revolt of specialized labor. The *self-acting mule*, the greatest invention of modern industry, put out of action the spinners who were in revolt. If combinations and strikes had no other effect than that of making the efforts of mechanical genius react against them, they would still exercise an immense influence on the development of industry.[62]

That is, even if in its simplest determination the result of trade-union action is limited in its transformative power to quantitative variations of the wage, Marx was already aware that it also carried within itself a further mediated potentiality. Namely, the determination of strikes as 'triggers' of technical innovations, such as the introduction of machinery or, to put it differently, the determination of the class struggle as a progressive active force in the development of the material productive forces of society. In this sense, the transformative powers of proletarian struggle also entailed the transformation of the wage form through the *qualitative* mutation of the material conditions of social labour and, therefore, in the social form of existence of the productive subjectivity of the workers themselves. But this determination as such did not involve the *immediate* production of the conditions for the social constitution of the fully conscious revolutionary subjectivity. Marx already knew that it was in the very nature of capital to constantly revolutionise the material conditions of social labour. And if we take those two insights together, a necessary conclusion follows which reinforces the social necessity of proletarian struggle. In short, the latter is not only the way in which the proletariat can put a limit to the fall of wages below subsistence level, but also the form in which they force capital to produce the conditions for its supersession, i.e. the development of the material productive forces of society.

> An oppressed class is the vital condition for every society founded on the antagonism of classes. The emancipation of the oppressed class thus implies necessarily the creation of a new society. For the oppressed class to be able to emancipate itself, it is necessary that the productive powers already acquired and the existing social relations should no longer be capable of existing side by side. Of all the instruments of production, the greatest productive power is the revolutionary class itself. The organiz-

---

[62] Marx 1976b, p. 207.

> ation of revolutionary elements as a class supposes the existence of all the productive forces which could be engendered in the bosom of the old society.[63]

We can see how Marx's science as practical criticism allowed him to discover how the class struggle is also determined as an active force in the production of the material conditions under which it will be produced as the personification of the historical necessity to abolish capital. Moreover, Marx insists against Proudhon that this transformation can only take place in the determinate concrete form which the latter rejected, namely, 'through the organisation of the revolutionary elements as a class'.

The Limits to Marx's Early Attempt at a Dialectical Revolutionary Critique of Political Economy

Thus far I have focused on the advances made by Marx in his development of the dialectical cognition as the most potent form of organisation of the political action of the working class. However, it should be obvious that at that time that development was still rudimentary. Marx was very far from accomplishing what *needed to be done*: the positive conscious development of the determinations of capital. Certainly, as I tried to show with my previous discussion, Marx had produced certain discoveries that allowed him to go beyond the 'utopianism' of Proudhon. But it should be noted that these were actually more like discrete insights whose real determinations and inner connections were still beyond Marx's horizon. Thus it would be more accurate to say that Marx only *hinted* at the discovery of the social necessity of the different forms of political action of the workers which aim at revolutionising capitalist society.

That this is the case is revealed by Marx's subsequent intellectual development immediately after *The Poverty of Philosophy*. The next scientific endeavour on which Marx embarked was an attempt to deepen his understanding of the determinations of wages and the necessary connection between their movement and the struggles of the workers through the formation of associations. This materialised in the manuscript edited as 'Wages', which formed the basis of Marx's lectures on the subject in Brussels published in 1849 as *Wage-Labour and Capital*. This betrays the fact that Marx himself was aware of the limits of the critique of political economy he had produced in those years.

---

[63] Marx 1976b, p. 211.

In fact, in the preliminary words to *Wage-Labour and Capital*, Marx explicitly acknowledges his deficit and states that it is the purpose of that work to cover it.

> From various quarters we have been reproached for neglecting to portray the economic conditions which form the material basis of the present struggles between classes and nations. With set purpose we have hitherto touched upon these conditions only when they forced themselves upon the surface of the political conflicts … But now, after our readers have seen the class struggle of the year 1848 develop into colossal political proportions, it is time to examine more closely the economic conditions themselves upon which is founded the existence of the capitalist class and its class rule, as well as the slavery of the workers.[64]

Marx then states that he attempts to explain the economic conditions upon which the class struggle, already 'proved' empirically in 1848, is based. And I take him to mean that he was going to develop the concrete determinations behind the necessity of the class struggle, the task that he had begun in *The Poverty of Philosophy*. And yet this first conscious attempt at a systematic presentation of the determinations of capital as the adequate form of the critique of political economy would also prove insufficient. In a nutshell, the conclusion that Marx draws regarding his investigation of the determinations of wages is that they have a tendency to fall as the result of the movement of the accumulation of capital. This he grounds in terms of the effect of the detailed division of labour on the value of labour (power), the displacement of labour brought about by the introduction of machinery and the inclusion of female and child labour which, in turn, increases the competition among labourers.[65] He then moves to another effect of the movement of capital accumulation which is to intensify its crisis tendencies. In turn, crises result in the further degradation of the living conditions of the working class since they increase the competition among them, thus putting the burden of their consequences upon the shoulders of the workers.[66] Certainly, when seen from the perspective of the explanation offered in *Capital*, this appears as a completely one-sided account which centres on workers whose productive subjectivity becomes degraded through capital's development of the system of machinery.

---

[64] Marx 1977, p. 197.

[65] Marx 1977, p. 227.

[66] Marx 1977, p. 228.

As an account of the necessity of class struggle, this work is still unsatisfactory. Marx seems more concerned to show the negative impact of capitalist development upon the living conditions of the working class than to provide a thorough investigation of the concrete determinations of the movement of wages and the role of the class struggle in that movement. Marx seems eager to provide a stronger foundation for the direct confrontation with those who claimed that there was some sort of harmony of interests between workers and employers. If the unchecked imposition of the will of the capitalist class leads to those degraded conditions, the working class cannot submit itself unconditionally to the interests of the capitalists but must affirm its own, antagonistic interests. The necessity of the struggle and the formation of associations is seen simply as a way of preventing wages from falling even below the ever decreasing 'minimum' or, when possible, to temporarily raise them above it. This account was still miles away from the one offered in *Capital*, where the question entails the distinction between labour and labour power, between the price and the value of labour power, the determination of the latter as an expression of the concrete materiality of the productive subjectivity of the labourers determined by the forms of production of relative surplus value, and so on.

These shortcomings are even more marked when considered in relation not just to the necessity of that limited form of the class struggle, but also to the development of the conscious revolutionary subjectivity of the workers. According to Marx, the associations are not just a means for the struggle over wages. More generally, they also serve to bring workers together and to constitute themselves as a class against the bourgeoisie. That is, it is the way in which their competition turns into its opposite, direct or conscious association. And this conscious collective action is the form that the revolutionary activity of the working class must take. Therefore, Marx sees these associations as a necessary 'training ground' for the revolutionary struggle of the class which would emerge under determinate material conditions (which capitalist development itself brings about, as he notes in the section that follows called 'Positive aspect of wage labour').

> If in the associations it really were a matter only of what it appears to be, namely the fixing of wages, if the relationship between labour and capital were eternal, these combinations would be wrecked on the necessity of things. But they are the means of uniting the working class, of preparing for the overthrow of the entire old society with its class contradictions … And if in their moments of philanthropy Messrs the bourgeois and their economists are so gracious as to allow in the minimum wage, that is, in the

> minimum life, a little tea, or rum, or sugar and meat, it must by contrast appear to them as shameful as incomprehensible that the workers reckon in this minimum a little of the costs of war against the bourgeoisie and that out of their revolutionary activity they even make the maximum of their enjoyment of life.[67]

Implicit in this account is the rather simplistic view that the revolutionary subjectivity of the workers is the result of the 'accumulation of experience of struggle', a kind of quantitative extension of the trade-union struggle. Marx does not offer here a proper basis for this view. He just wants to say something about the transition between non-revolutionary and revolutionary forms of working class subjectivity in order to show the transitory nature of capital. But in light of the lack of a proper account of the concrete determinations of the latter, he can only offer a general statement based on the abstract self-development of the consciousness of the workers which is indifferent to the social determinations producing the different forms of working class subjectivity.

In this sense, Marx did not advance much from the 'phenomenology' of organisational forms of the class struggle already offered in *The Poverty of Philosophy*. Initially, workers organise just in the form of combinations. But then, this merely 'economic' form of the class struggle takes increasingly political forms. In a passage already quoted, Marx states:

> But the maintenance of wages, this common interest which they have against their boss, unites them in a common thought of resistance – *combination* … If the first aim of resistance was merely the maintenance of wages, combinations, at first isolated, constitute themselves into groups as the capitalists in their turn unite for the purpose of repression, and in the face of always united capital, the maintenance of the association becomes more necessary to them than that of wages … In this struggle – a veritable civil war – all the elements necessary for a coming battle unite and develop. Once it has reached this point, association takes on a political character.
>
> Economic conditions had first transformed the mass of the people of the country into workers. The combination of capital has created for this mass a common situation, common interests. This mass is thus already a class as against capital, but not yet for itself. In the struggle, of which we have noted only a few phases, this mass becomes united, and constitutes

---

[67] Marx 1976f, p. 435.

> itself as a class for itself. The interests it defends become class interests. But the struggle of class against class is a political struggle.[68]

The first remarkable point of this passage is the presence of the distinction between 'class in itself' and 'class for itself'. But note as well that this distinction refers not, as is generally interpreted, to the fully conscious revolutionary forms of the class struggle, but rather to the class struggle in general. The class constituted as a class 'for itself' just means the class affirming its essential antagonistic relation to the bourgeoisie through the political action of its members, whatever form the latter takes. So it does not necessarily imply a fully developed revolutionary proletariat consciously transforming capitalist society into the free association of individuals through its self-abolition as a class. Secondly, it is true that Marx makes a distinction between forms of the class struggle that do not take a political form and political struggles. But note that not only does he not refer to the former as merely 'economic', but he also makes clear how class struggle in a political form is a necessary form which the embryonic non-political forms of struggle tend toward. Thus these passages clearly go against the Leninist rigid separation between economic struggles and political struggles, the former developing spontaneously but the latter needing the external intervention of a revolutionary vanguard. That is why that quote has often been used by defenders of so-called 'spontaneist' accounts of the development of revolutionary subjectivity (along the lines of Luxemburg) to make a case for their anti-Leninist position.[69] However, although those approaches are right in their criticism of the Leninist separation between economic and political struggles, they are wrong in identifying Marx's reference to the political character of the struggle with its revolutionary form. When Marx refers to the 'political struggle' between the two classes, he refers to the class struggle in general, not just to its revolutionary form. Its political character derives from the following interrelated points. Firstly, it objectively reaches the universality of the members of the class. Secondly, it transcends the confrontation with capitalists within the boundaries of individual capitals or restricted groups of them within branches of production, to become directly centred on the struggle over the form of political representation of social capital, i.e. the state. In this way it becomes determined as the form through which the directly general conditions of social reproduction are established.[70] 'Non-political' forms of the class struggle are, for Marx, those first manifestations of the class struggle in which the proletariat had not yet affirmed itself as a class with an independent political representation.

---

[68] Marx 1976b, pp. 210–11.

[69] Müller and Neusüss 1975.

[70] Marx 1965.

Be that as it may, it is clear that the inadequacy of this early formulation of the question by Marx paves the way for all this confusion. In particular, taken at face value, Marx's formulation can certainly be read as a kind of 'Luxemburgist' approach based on an 'accumulation-of-experience-through-struggle' theory of revolutionary subjectivity. Briefly put, for that approach, revolutionary subjectivity is the product of the 'self-development' of class consciousness in the course of the struggle against capital, a potentiality which is carried by any form of the class struggle. While it is evident that the different (antagonistic) forms of class consciousness can only develop through the political actions of the workers against capital, this does not mean that class struggle as such is the self-determining ground for the production of revolutionary subjectivity. In fact, the picture of working-class consciousness as set into motion by itself, now growing, now retreating – that is, as essentially self-moving – is the one we get when externally grasped in its apparent concrete forms. Only as an expression of determinate material conditions does proletarian struggle acquire a conscious revolutionary form. This is what Marx makes clear immediately after the quoted passage when he states that 'the organization of revolutionary elements as a class supposes the existence of all the productive forces which could be engendered in the bosom of the old society'. However, this is no more than a very general statement, which does not do much as an account of the qualitatively specific form that those productive forces must acquire, or of the historical process that begets them, including the role of the different forms of proletarian political action in it.

Clearly, then, Marx's investigation of the concrete determinations of the political action of the working class, i.e. the critique of political economy, was at that time in an embryonic stage. Therefore, Marx could not but eventually *represent* the qualitatively different forms of the class struggle in terms of the *quantitative* difference of their respective scope. That is why, when read as a self-contained account, it could be read in a simplistic and mechanistic fashion, as involving a linear and continuous expansion of working-class organisation until reaching its truly revolutionary form. Or, alternatively, as a 'contradictory learning process', with steps forward and setbacks, but always potentially self-developing into revolutionary subjectivity. However, when read from the vantage point of Marx's more developed dialectical account in *Capital*, a different picture emerges. On the one hand, it is clear that Marx was (becoming) aware of the need to grasp the specific qualitative determination immanent in each of the forms of the class struggle in order to discover their necessity.

On the other hand, Marx's insufficient development of the critique of political economy allowed him to offer just a glimpse of the concrete determinations involved in those social forms. As a result of this, when those determinations do appear, however deficiently, in Marx's discussion (for instance, regarding the relation between 'associations' and the movement of the wage), they give the impression of being merely the 'objective conditions' for proletarian action. In turn, those conditions appear as 'moulding', 'limiting' or 'constraining' the deployment of the otherwise self-determining potentiality of the 'subjective factor'. In a nutshell, when externally grasped, the social determinations of working-class consciousness and action become reduced to a 'context' in which the latter freely develops (maybe as a 'response' to the latter).[71]

I would like to argue that in both their merits and shortcomings, these texts embody a wider significance beyond the concrete questions they address and the specific (and limited) answers they give. For, when seen from the perspective of the direction that Marx's subsequent scientific development took, we can see those texts as embodying a programmatic significance regarding the specific form of dialectical cognition in its immediate condition of conscious organisation of human transformative action. The starting point of Marx's investigation, the very form in which he attempted to address the questions to be answered, and the limitations he encountered, all reveal *the general form of motion of scientific knowledge determined as practical criticism*. This, I think, is the lesson that Marx drew from his polemic against Proudhon and, a little bit later, from the defeat of the 1848 revolutions.

It is my claim that Marx became aware that only through the positive reproduction in thought of the determinations of capital and its form of movement could the working class develop its revolutionary consciousness. Science, as Alfred Schmidt puts it, becomes determined as the 'conscious product of historical movement'.[72] Moving forward in its production and giving it a socially reproducible form – i.e. a book – thereby turned out to be a most urgent political task. In a letter to Meyer from 1867, in which he apologises for the tardiness of his reply, Marx speaks in this way about his activities of the previous years:

---

[71] In fact, it could be argued that the whole history of Marxism revolves around the attempt to solve this (false) antinomy between the forms of objectivity and subjectivity of the capital relation. This illusion arises because, as we have seen, when the inner connections between social forms is broken by logical representation, abstract and concrete forms appear side by side as self-subsistent entities, which, at most, interpenetrate. And this applies to the relation between the objective and the subjective forms of the alienated social being as well. For excellent historical accounts of this problematic, and for thought-provoking reflections, see Aufheben 1993, 1994 and 1995; Marramao 1975/6 and 1982; Jacoby 1971 and 1975.

[72] Schmidt 1983, p. 29.

> Why then did I not answer you? Because I was the whole time at death's door. I thus had to make use of **every** moment when I was capable of work to complete my book [*Capital*] to which I have sacrificed my health, happiness, and family. I hope this explanation suffices. I laugh at the so-called 'practical' men and their wisdom. If one wanted to be an ox, one could, of course, turn one's back on the sufferings of humanity and look after one's own hide. But I should really have thought myself *unpractical* if I had pegged out without finally completing my book, at least in manuscript.[73]

That book, *Capital*, turned out to be Marx's most developed attempt to concretise the general form of motion of dialectical cognition determined as revolutionary science and outlined in this first part of the book through the discussion of Marx's early works. In the second part of this book, I shall attempt to demonstrate this through a critical reading of Marx's mature critique of political economy. The latter, I shall argue, is but the scientific development of the revolutionary consciousness of the proletariat becoming aware of its own social determinations in their unity and, therefore, of the historical task which, by virtue of them, it will be compelled to do: the conscious production of communism as the most developed form of the critique of capital.

PART 2

Dialectical Knowledge in Motion: Revolutionary Subjectivity in Marx's Mature Critique of Political Economy

⁂

CHAPTER 4

The Commodity Form and the Dialectical Method

Introduction

In the Preface to the First Edition of *Capital*, Marx makes evident that he was fully aware of the complexity entailed by the first steps in the critique of political economy. Thus he states:

> Beginnings are always difficult in all science. The understanding of the first chapter, especially the section that contains the analysis of commodities, will therefore present the greatest difficulty.[1]

The endless debates over the real meaning and implications of Marx's discussion of the commodity form seem to suggest that, if anything, Marx's warning actually fell short of the real difficulties at stake. And whether it is explicitly acknowledged or not, it is clear that the diverse readings of Marx's critique of political economy entail different political implications.[2] In fact, it could be argued – and, hopefully, this chapter and the ones that follow will substantiate this claim – that those 'minutiae', which the discussion of the determinations of the commodity form 'appear to turn upon',[3] are of paramount importance for the conscious organisation of the revolutionary action of the proletariat. This is shown not only in Marx's insistence on the impossibility of correctly grasping the determinations of those more abstract social forms from the bourgeois standpoint of political economy,[4] but also in the central role they played in his critique of the ideological representations of them coming from the working class movement itself, e.g. Proudhonian socialism.[5]

[1] Marx 1976g, p. 89.

[2] Dimoulis and Milios 2004.

[3] Marx 1976g, p. 90.

[4] Marx 1976g, p. 174.

[5] See Clarke (1994) and Shortall (1994) for good reconstructions of Marx's critique of Proudhonian socialism based on the latter's misunderstanding of the nature of the commodity and money forms. Thus, the gist of Marx's critique of Gray's proposal to preserve private commodity production while replacing the money form with labour time certificates issued by a national bank, comes down to the latter's inability to comprehend the immanent necessity of the value of commodities to take on the independent form of money (see Elson 1979b, pp. 135–6). Similarly, in the *Grundrisse*, Marx ridicules Darimon's proposal of abolishing the privilege of money (that of being directly exchangeable for all commodities) by making 'by decree'

© KONINKLIJKE BRILL NV, LEIDEN, 2016 | DOI: 10.1163/9789004306608_006

It is my view that this diversity in the ways in which Marx's followers have read the ideal reproduction of the determinations of the commodity form contained in *Capital* is closely connected to the varied methodological perspectives from which those authors have attempted to grasp the former. In other words, those different interpretations of the actual *content* of the first section of *Capital* express different understandings of the very *form* of scientific knowledge unfolded in that book. Seen the other way round, and this is the fundamental issue to be discussed in this chapter and the next, I would argue that only on the basis of a sound comprehension of the dialectical method can the implications of Marx's investigation of the commodity form be uncovered in all their plenitude.

The need to reconsider Marx's presentation of the commodity form in Chapter 1 of *Capital* through a reassessment of his dialectical method (in particular, its connection to Hegel's *Science of Logic*) has been widely recognised by a growing number of scholars. In effect, the last twenty to twenty-five years have witnessed a renewed interest in Marx's dialectical method and its implications for value theory.[6] However, despite all the light that these works have cast on the form of Marx's argument, they have been mainly focused on the *synthetic* aspects of Marx's dialectical presentation (i.e. on the exposition of the dialectical movement from the 'abstract to the concrete'). In this sense, it could be argued that this literature has glossed over two further fundamental aspects of Marx's dialectical method, which I have discussed in the previous chapter. First, those works have not sufficiently thematised the peculiar role of the *phase of analysis* in Marx's dialectical investigation generally and in his presentation in *Capital* in particular. Second, they have not paid sufficient attention to the *specific form of the analytical process within dialectical thought*.[7] My aim here, therefore, is to fill these gaps in the literature.[8]

---

all commodities directly exchangeable (Marx 1993, p. 126). In all these cases, the common thread of the Marxian critique lies in the incapacity of those authors to grasp the necessary inner connection between the commodity and money forms.

[6] See, among others, Murray 1988; Smith 1990a; Moseley 1993; Moseley and Campbell 1997; Arthur 2002b; Albritton and Simoulidis 2003.

[7] The distinction between analysis (in the sense of dissection of the 'whole' into 'parts' or 'identification of differences') and synthesis (in the sense of reconstitution of the 'unity' of the whole) is not peculiar to dialectics. As I argue below, what sets the latter apart from formal-logical methodologies is the specific *form* taken both by the analytical and synthetic processes in dialectical thought. Zelený provides a concise discussion of the different meanings of analysis and synthesis in science and philosophy, which also traces back their intellectual lineage (see Zelený 1980, Chapter 10).

[8] These other aspects have not been entirely absent in the literature. However, they came up in

The main purpose of this chapter is to provide a methodologically minded critical reading of Marx's argument about the determinations of the value form of the product of labour in the first chapter of *Capital*. Through this reading, I shall substantiate the claim made in the first part of the book that *Capital* crystallises the positive deployment of the methodological insights gained by the 'young Marx' through his critique of Hegel, the Young Hegelians and Proudhon. In other words, I shall show that *Capital* contains Marx's dialectical method, as discussed in the first part, concretely set into motion for the intellectual reproduction of capitalist social forms. While this latter statement is true of the book as a whole (or, at least, to its first volume, the only one that Marx prepared for publication), the detailed examination of the structure of the first three sections of Chapter 1 is of particular significance. In effect, the exposition of the determinations of the commodity form contained there is, arguably, the most paradigmatic place where he presented the concrete workings of his dialectical method of research in the indissoluble unity of its analytic and synthetic stages.[9] On these grounds, additionally, I will try to show that many of the confusions and misunderstandings among both followers and critics of Marx spring from an inadequate grasp of the dialectical structure of Marx's exposition.

Finally, this close examination of the expositional structure of the first three sections will set the stage for the discussion in the following chapter of this book, in which I discuss Marx's presentation of the fetish character of the commodity. As will became evident later on, only by properly grasping the precise content and formal structure of the first three sections of Chapter 1 of *Capital* can the specific object of exposition and systematic significance of the section on 'commodity fetishism' be fully appreciated.

---

the debate among 'new dialecticians' relatively late (Murray 2002; Reuten 2000) and have not been pursued any further until recently (see Reuten 2014, who does address in great detail the connection between analysis and synthesis, and that between inquiry and presentation, in systematic dialectics). See also Brown et al. (2002) for a discussion of some of these issues through a comparison between critical realism and systematic dialectics. Be that as it may, it is my view that compared to the light thrown on the synthetic aspects of Marx's method of presentation, the nature of the relation between analysis and synthesis in the presentation, and the way in which this relates to the formal determinations of the dialectical inquiry, have not been explored with the same degree of clarity.

Inquiry and Presentation, Analysis and Synthesis: On Some Controversies over the Initial Passages of Marx's Argument in *Capital*

In *Capital*, Marx puts into motion the discoveries which allowed him to overcome the limitations of his early account of alienated labour and its supersession. In contradistinction to the *Paris Manuscripts*, and as he clearly states in the *Marginal Notes on Adolf Wagner*, he takes as a point of departure neither the concepts of political economy nor any concept whatsoever,[10] in order thereby to discover alienated labour as their presupposition. As the title of his most important work denotes, the subject whose determinations the dialectical investigation proceeds to discover and present is *capital*, which, as the alienated subject of social life becomes 'the all-dominating economic power of bourgeois society' and must therefore 'form the starting point as well as the finishing point' of the ideal reproduction of the concrete.[11] In this sense, Marx's exposition in *Capital* does not advance towards the discovery of alienation, but instead starts from what the dialectical inquiry revealed as its most abstract and general form.[12] He starts with the immediate observation of the simplest *concretum* in which the alienation of labour is expressed in order to develop the real determinations specific to this social form.[13] As has now been widely acknowledged, this starting point is not an ideal-typical – or worse, historically existent – simple commodity-producing society, as in the orthodoxy derived from Engels and popularised by authors such as Sweezy and Meek.[14] In Marx's own words, he starts with the commodity as the 'economic cell form of bourgeois society'.[15]

> We begin with the commodity, with this specific social form of the product – for it is the foundation and premise of capitalist production. We take the individual product in our hand and analyse the formal determinants that it contains as a commodity and which stamp it as a commodity.[16]

[16] Marx 1976c, p. 1059.

However, Marx's presentation does not directly start with the essential determinations of the commodity form, but rather starts from the immediate observation of an individual commodity in its outward appearance.[17] In a presentation which will prove full of 'metaphysical subtleties and theological niceties',[18] Marx shows that what determines the commodity as a form of social wealth is not only that, as any product of labour, it possesses a use value, but that the latter acts as the material bearer of a second attribute, namely, exchange value. The further analysis of the commodity reveals that exchange value is actually the form of expression of a content distinguishable from it – the value form, or the attribute of general exchangeability of the commodity – the substance of which resides in the abstract labour congealed in it, and whose magnitude is consequently determined by the socially necessary abstract labour time required for its production.

The above line of reasoning has been the subject of all kinds of objections put forward by different interpreters of Marx. As I argue below, those reservations about Marx's argument have their source in an inadequate comprehension of, or insufficient attention to, the nature of the crucial distinction between two different moments involved in Marx's dialectical inquiry and presentation, namely, the stage of analysis and that of synthesis. In particular, I think that it is confusion over these questions that lies at the basis of widespread critiques of Marx's line of argument about the determinations of the commodity form;

---

[17] Properly speaking, there is a previous step in Marx's presentation. He first starts with the form in which social wealth appears in capitalist society, namely, an 'immense collection of commodities' (Marx 1976g, p. 125), the individual commodity being its elementary form. The unfolding of the determinations behind this appearance is not completed until Volume II, where the unity of the movement of the total social capital itself, in the form of the circuit of commodity capital, is revealed as positing social wealth in the form of an immense collection of commodities (Marx 1978, pp. 174–7). The secondary literature on Volume II is remarkably limited compared to what has been written on Volumes I and III. Certainly, there has been a lot of discussion of the final part on the schemes of reproduction, misguidedly revolving around the notion of a mechanical impossibility of capitalist reproduction as constituting the limit to capital (see Rosdolsky 1986, for a survey of the early classical debates on that question). But the first part of Volume II has been generally neglected. Some of the few works available that deal in some detail with aspects of the former include: Fine 1975; Shortall 1994; Fine and Saad-Filho 2003; Arthur and Reuten 1998. On the circuit of capital, see especially the contribution by Arthur (1998a) in the latter book. More recently, David Harvey has contributed to redress the situation in the second volume to his *Companion to Marx's Capital* (Harvey 2013).

[18] Marx 1976g, p. 163.

not only by well known critics such as Böhm-Bawerk,[19] but also among some of Marx's disciples.[20] In brief, the general thrust of those objections is as follows: in *Capital*, Marx did not provide an adequate 'logical proof' that commodities have a 'something' in common and that that 'something' is congealed abstract labour.[21]

The first point at stake in this objection has already been forcefully made by other scholars, so I will refer to it only briefly. In a nutshell, the question comes down to the radical methodological difference which, as Meikle insightfully notes, separates Marx's dialectical approach to science from the formalism and atomism of bourgeois conceptions.[22] Clearly based on the latter, Böhm-Bawerk's objections came from someone who could only see science as a purely

---

[19] Böhm-Bawerk 1975.

[20] Thus both Reuten (1993, p. 107) and Arthur (1993, p. 76) agree that Böhm-Bawerk's objections to Marx's line of reasoning about abstract labour as the substance of value are justified; not because Marx is wrong in seeing abstract labour as the substance of value, but because his grounding of that point is defective from a 'systematic dialectical' perspective. This objection can actually be traced back to Hans-Georg Backhaus's groundbreaking essay of 1969, 'On the Dialectics of the Value-Form' (Backhaus 1980, pp. 99–100). A non-Ricardian, value-form critique of Backhaus (and defence of Marx's argument) can be found in Murray (2013).

[21] A good and concise account of the essence of this critique can be found in Kay (1979, pp. 48–58). See also Park 2003. Specifically, Böhm-Bawerk objected that Marx did not take into consideration common properties other than being products of labour – e.g. utility, scarcity, and so on – as possible determinants of exchange value (Böhm-Bawerk 1975, pp. 74–5). In this sense, it is worth noting that in the process of *inquiry* Marx did consider – but discarded and, hence, excluded from the *presentation* – 'utility in general' as the substance of value. This is evidenced by the following remarks from the preparatory *Manuscripts of 1861–63*: 'We have seen that the basis of value is the fact that human beings relate to each other's labor as equal, and general, and in this form social, labor. This is an abstraction, like all human thought, and social relations only exist among human beings to the extent that they think, and possess this power of abstraction from sensuous individuality and contingency. The kind of political economist who attacks the determination of value by labor time on the ground that the work performed by 2 individuals during the same time is not absolutely equal (although in the same trade), doesn't yet even know what distinguishes human social relations from relations between animals. He is a beast. As beasts, the same fellows then also have no difficulty in overlooking the fact that no 2 use values are absolutely identical (no 2 leaves, Leibniz) and even less difficulty in judging use-values, which have no common measure whatever, as exchange values according to their degree of utility' (Marx 1988, p. 232).

[22] Meikle 1985, Chapter 3.

'logical construct' and not the reproduction in thought of 'how things essentially are'.[23] Thus, with 'the characteristic empiricist gap between "truths" and the entities they are supposed to be true of',[24] he could only read Marx's initial pages as an abstract, formal process of 'logical proof'.[25] The possibility that those pages unfold the real nature and specific self-movement of a determinate content (the commodity form of the product of labour) and do not contain a formal deduction was beyond Böhm-Bawerk's formalistic field of vision.[26]

Secondly, and more important for the purpose of this chapter, at stake here is another aspect of Marx's argument in the first pages of *Capital* that has not been sufficiently or satisfactorily explored by most scholars: the specific nature and significance of the difference between the phase of analysis and that of synthesis within a dialectical exposition. This double movement in the dialectical *presentation* is not an arbitrary stylistic or rhetorical strategy introduced by Marx, but, as discussed in the first part of this book, reflects a real difference characterising the specificity of dialectical *inquiry*. The latter must involve *both* identification of the different forms taken by the subject whose determinations the dialectical investigation attempts to reproduce in thought (i.e. the analytical separation between social forms according to their relative degree of concreteness) *and* the 'tracking down of their inner connection' (i.e. the *synthetic* discovery of the immanent real necessity linking those different forms).[27] A fundamental implication follows from this: the exposition of the

---

[23] Meikle 1985, p. 80.

[24] Meikle 1985, p. 79.

[25] As Sayer (1979, pp. 94–5) notes, Althusser and Balibar (1968) and his British followers (Hindess and Hirst 1975 and 1977) fell prey to this appearance.

[26] Kay 1979, pp. 51–2. Besides, it is to be noted that Böhm-Bawerk completely missed the actual object of Marx's presentation in Chapter 1 of *Capital*, which is the commodity and not the causal determination of exchange ratios (Kliman 2000, p. 104).

[27] Marx 1976g, p. 102. Here my approach differs from that of both Murray and Reuten. The former seems simply to identify analysis with inquiry (what he calls 'phenomenology'), and synthesis with presentation (Murray 2000, pp. 36–8). Reuten does allow for synthetic moments in the process of inquiry, but only as 'provisional outlines of inseparability of phenomena' (Reuten 2000, p. 143). Moreover, although he is right to see the need for the dialectical presentation to be fundamentally synthetic, he does not fully explore the possibility that the dialectical researcher presenting the results of the inquiry may include 'stylised' moments of analysis in order to highlight the unity of the dialectical process of cognition. He only mentions this possibility in passing when discussing Banaji's argument about the twofold starting point of Chapter 1 of *Capital* (Banaji 1979, pp. 36–40; Reuten 2000, p. 158). But as I argue below, this presentational strategy plays a central role at least in

explanation proper of the necessity underlying the relations between different social forms – what would amount to a 'logical proof' in the language of formalistic methodological approaches – is not to be found in the dialectical *analysis*, but in the *synthetic* movement of the exposition. Now, since it is in the latter only that the unfolding of the real movement of determination – hence the explanation – actually takes place, the presentation of the findings of the dialectical inquiry could take, in principle, a fully synthetic form.[28] However, this is not the way Marx structured his dialectical exposition in Volume I of *Capital* (the only one he edited for publication himself); this exposition tends to include, in a 'stylised' form, brief presentations of the analytic process.[29] Since this peculiar structure of Marx's presentation of the determinations of the commodity form actually recurs throughout most of Volume I, and given that its misunderstanding has caused so many controversies among critics and followers alike, it might be worth providing further elaboration on this last point.

In a nutshell, this structure of Marx's dialectical presentation starts by taking the immediate concrete appearance of the determinate social form at stake. Through a brief analytic movement, it subsequently uncovers its inner essential determination.[30] The exposition then proceeds by synthetically unfolding the realisation of that (more abstract) determination. This stage goes on until the specific potentiality defining the essential determination of the social form

---

the whole of Volume I. Fineschi (2009) offers an interesting overview of German debates in the 1970s dealing with the connection between Marx's method of inquiry and his method of presentation.

[28] Iñigo Carrera 2008, p. 317.

[29] On the role and the pros and cons of this analytic moment in the peculiar structure of the dialectical exposition in *Capital*, Volume I, organised around presentational 'nodes', see Iñigo Carrera 2008, p. 323.

[30] Marx sometimes includes *apparent* (hence flawed) analytical paths in his exposition that are revealed to be such through a movement that leads the reader back to the unmediated starting point, that is, without making any progress towards the discovery of the underlying specific determination defining the object under scrutiny (Iñigo Carrera 2008, p. 320). The presentational role of the inclusion of these flawed analytical movements is mainly pedagogical; they serve to place more emphasis on the correct analytical path. Marx's consideration of the possibility that the particular material properties of the commodity under investigation constitute the more abstract form behind the attribute of general exchangeability is an example of this (Marx 1976g, pp. 127–8). Incidentally, it is to be noted that this is the real meaning of what Böhm-Bawerk mistakenly saw as Marx's 'method of exclusion', through which he allegedly provided a 'purely negative proof' of abstract labour as the substance of value (see Böhm-Bawerk 1975, pp. 68–9).

under scrutiny, and whose realisation the exposition is ideally reproducing, negates itself as immediately carried by that abstract social form to become affirmed as immediately pertaining to the more concrete form into which it has metamorphosed. This signals that the first presentational node has been exhausted. A new one thereby begins, but now with the more concrete form whose genesis has been traced in the former as the subject of the movement to be ideally reproduced. However, the new node does not directly start with the inner determinations of this more concrete social form but, again, with its immediate manifestation. An analytic movement therefore precedes the former.[31]

Returning to my main argument about the general aspects of this formal structure of Marx's presentation: as mentioned above, it is the exposition of the *dialectical synthesis* that reveals the 'why' of real relations. The analytic stage only separates a social form from a more abstract one, whose realised potentiality it carries within itself in the form of its own immanent potentiality. In this sense, the analytic stage is about not the *why*, but the *what*. Evidently, since the separation of social forms according to their relative degree of abstractness/concreteness ideally expresses the objective necessity (the real relations) residing in the object, and is not the product of the subjective caprice or imagination of the scientist, the mere reference to the 'what' carries implicitly some hint of the 'why'. Thus, if the dialectical analysis reveals that the value form is the concrete form in which the objectification of the abstract character of private and independent labour affirms itself as an abstract form, the separation between the two already says something about the real relation involved. But this something is no more than, as it were, a 'pointing out', an observation. The actual ideal reproduction of that inner connection – the explanation – takes place in the synthetic movement.[32]

---

[31] At this juncture, it is important to point out that, in the dialectical *inquiry*, analysis and synthesis overlap in the concrete intellectual labour of the scientist. Thus the actual activity of inquiry of the dialectical researcher involves a constant passage from phases of analysis to phases of synthesis, and therefore they do not immediately appear as distinct aspects of the process of cognition. However, they do constitute two real determinations of the dialectical method and therefore it is crucial to bear their difference in mind. And it is this real difference which appears 'in its purity' in the dialectical exposition, when the author decides to reproduce the analytical stage (whether in whole or in part) in the presentation.

[32] In his *Science of Logic*, Hegel refers to this distinction between the role of analysis and synthesis as the difference between the *apprehension* of what is and its *comprehension* (Hegel 1999, pp. 793–4). However, Hegel develops this distinction as pertaining to the 'under-

With this in mind, it is easy to understand the main reason why the criticisms levelled at Marx over his inadequate explanation of abstract labour as the substance of value in the first pages of *Capital* are not simply based on a misunderstanding about the particularities of his argument, but are completely off the mark. To put it simply, those critiques search for an explanation in the wrong place, that is, in the pages where Marx is just presenting the analytic separation of real forms, which comprise the first two sections of Chapter 1. Marx's alleged explanation of why abstract labour is the substance of value in those pages sounds unconvincing simply because it is not there. As we will see, the unfolding of this particular 'why' only occurs in section three, which discusses exchange value as the form of manifestation of value. Before engaging in that aspect of Marx's presentation of the determinations of the commodity form, let us first probe deeper into the *specifically dialectical* form of the analytical moment that precedes it.[33]

---

standing', that is, an underdeveloped form of thought. Dialectical cognition, 'speculative science' in Hegel's parlance, is for him essentially synthetic (see Caligaris and Starosta 2014).

[33] Regarding Chapter 1 in particular, this structure has been recognised by Banaji (1979) and Elson (1979a). However, they both seem to reduce the content of the synthetic stage of the presentation simply to the question of revealing exchange value as the necessary mode of expression of value, i.e. to the formal necessity of the money form. But as I argue below, the latter is precisely the moment when Marx is synthetically unfolding the necessity of privately performed abstract labour as the substance of value. Neither Elson nor Banaji explicitly address the question of where exactly the 'why' of abstract labour as the substance of value can be found. Elson in particular seems to concur with Rubin (see below) that it is actually in section 4. Murray (1988, pp. 148–9) rightly sees the structure of Chapter 1 as comprising a 'double movement' of form to content and then from content to form. However, presumably reducing the dialectical movement to the synthetic stage, he sees nothing particularly dialectical in the first movement; hence his analogy with Descartes's analytical reduction of the bit of wax to primary quality matter, i.e. a search for a 'third party' or common element. In reality, the general point about the twofold movement of analysis and synthesis in Marx's exposition had already been made by Rubin in his seminal work on the theory of value (Rubin 1972, p. 113). However, as I shall discuss below, his understanding of the way they structure the exposition is, I think, incorrect. Furthermore, although Rubin does distinguish between the analytic and the synthetic (genetic, as he calls it) stages of the presentation, he seems to restrict the dialectical method to the latter (Rubin 1978, p. 110). In this way, the specific form of the dialectical analysis vis-à-vis the analysis of representational scientific thought is overlooked.

The Phase of Analysis

In contrast to the claims of those critics referred to above, I think that in the opening pages of Chapter 1, Marx is not searching for a common property in commodities. Rather, he is searching for (i.e. not yet unfolding) the specific determination defining the potentiality of the commodity as a historical form of social wealth.[34] This potentiality Marx initially 'discovers' by looking at the use value of the individual commodity, which in capitalist societies acts as bearer of a second, *historically specific* attribute of the products of labour, namely, *exchange value*. Two things follow from this. First, inasmuch as it is materially borne by the use value of the commodity, this attribute is *intrinsic* to the commodity itself. Second, as argued above, Marx is not *trying to prove logically the existence of a common property*, but *the commodity itself*, in its immediacy, shows that it *has* that 'common property' immanent in it.

Here a problem might arise, because Marx does not explicitly say in what that second attribute of the commodity consists. He just names it (exchange value) and then directly proceeds to its analysis. I think that the reason for this is that the meaning of that attribute was self-evident in the name itself in light of its everyday usage at that time. The fact that commodities have 'exchange value' simply means that they have the *power of exchangeability*, that is, *the 'fantastic' aptitude to be transformed into a different use value without the mediation of any material transformation in its bodily existence*.[35] What immediately follows in Marx's exposition is, then, the *dialectical analysis* of this social power of exchangeability of commodities. That is, Marx proceeds to answer what is the source of this specific potentiality intrinsic to the commodity, i.e. what is the abstract form appearing in the concrete form of the power of exchangeability.

---

[34] The difference between these two forms of grasping Marx's argument in the first pages of *Capital* expresses the difference between the dialectical form of the analysis and that of representational thinking. Many authors have highlighted the distinction between the abstractions of dialectics and those of representational thought as one between 'real abstractions vs. mental generalisation' (Saad-Filho 2002) or 'empiricist abstractions vs. determinate abstractions' (Gunn 1992). 'Empiricist abstractions' have also been called 'formal abstractions' (Clarke 1991a) or 'general abstractions' (Murray 1988). However, as Iñigo Carrera (2008, p. 282) points out, what most authors have overlooked is that the difference in the respective kinds of abstraction emerges as a result of the very *form* of the process of cognition on the basis of which those abstractions are identified. My argument is that this difference in form not only applies to the synthetic or genetic phase – as is usually assumed – but *crucially pertains to the process of analysis as well.*

[35] Iñigo Carrera 2007, p. 216.

As happens with every real form, the first thing he encounters when facing the exchangeability of the commodity is its *immediate manifestation* – the quantitative relation 'in which use-values of one kind exchange for use-values of another'.[36] Thus, the first step in the analysis of exchangeability is the separation of the *content and form* of that specific attribute of the commodity, this being the only way in which one can penetrate through the concrete form in which an abstract form presents itself. Again, this is the immediate object of Marx's exposition in the passages that follow, and not the search for a 'common something' or 'third thing', the existence of which the distinction between form and content presupposes.[37] This separation between form and content reveals that the different *particular* exchange relations that a commodity establishes with other commodities are actually expressions of something else that inheres in commodities and which gives them the identical *qualitative* potentiality of *general exchangeability* in a certain *magnitude*. Once form and content of the attribute of general exchangeability are distinguished, Marx continues with the analysis of the latter, which consists in separating that form of general exchangeability from the abstract form whose necessity it carries within itself as its 'other'. The particular form that this analysis takes is, again, not the search for a common element, but the search for the determinate action which posits that specific attribute existing in commodities.[38] That action, Marx states, is a human action in one of its facets, namely, productive labour in its general character or abstract labour. Commodities have this attribute of general exchangeability as products of the abstract character of the labour objectified in them.[39]

---

[36] Marx 1976g, p. 126.

[37] In order to avoid confusions, I am not implying that the existence of a common property and exchange equivalence are not important elements of Marx's arguments. My point is that Marx is not *logically proving* the existence of a common property or that the only possible substance of that common property is abstract labour. He '*finds*' that common property immanent in the commodity (actually, its immediate manifestation), and then proceeds to its *dialectical* analysis (i.e. separation of form and content). See Kicillof and Starosta 2007a and Iñigo Carrera 2007, for a fuller discussion of why being the products of the abstract character of labour is the only reasonable determination behind the value of commodities.

[38] Iñigo Carrera 2007, p. 218.

[39] Admittedly, Marx's transition to abstract labour might seem abrupt and too unproblematic. But here it is important to bear in mind that insofar as it presents results laboriously obtained through previous research, the dialectical exposition has a fluidity which does not reflect the complexity of the real activity of analysis in the process of inquiry, in which the researcher might have mistakenly taken other analytical steps. In principle, the latter

And here there is a tricky aspect in Marx's presentation, which might have contributed to much of the confusion. Because, although at that stage of the argument he has already shown that the common 'something' is the form of general exchangeability, he does not actually *name* it until separating, in turn, that form from its content or substance.

> All these things now tell us is that human labour power has been expended to produce them, human labour is accumulated in them. As crystals of this social substance, which is common to them all, they are values – commodity values [*Warenwerte*].
>
> We have seen that when commodities are exchanged, their exchange value manifests itself as something totally independent of their use value. But if we abstract from their use value, there remains their value, as it has just been defined. The common factor in the exchange relation, or in the exchange value of the commodity, is therefore its value.[40]

Marx names that intrinsic attribute of general exchangeability which is manifested in exchange value, and which is posited by the abstract character of labour, *value*.[41] Now, in opposition to the claims of a great deal of contempor-

---

do not need to be included in the dialectical presentation, although the researcher might decide to present them in order to stress the correct analytical path that leads to the discovery of the determinate content behind a specific social form (see footnote 30 above). Hence, when considering the action that posits the form of general exchangeability of commodities, the only actions other than labour that Marx contemplates (and obviously discards) are purely natural actions. In other words, he does not consider other kinds of human action, such as exchange or subjective 'valuation' of the utility of the commodity. However, as Iñigo Carrera (2007, p. 24) points out, neither of those other human actions can explain the *two* features that, at that stage of argument, Marx has already discovered as constituting the commodity. First, the fact that the attribute of general exchangeability is specific to capitalist society (subjective valuation of utility is a human action which occurs in non-capitalist modes of production as well, and yet it does not objectify in the value form of the product). Second, the value form is materially carried by the use value of the commodity as its bearer, which means that the action that posits those two attributes must be the same (in this sense, exchange is an action which *presupposes* rather than posits the existence of the use value of the commodity).

[40] Marx 1976g, p. 128.

[41] This postponement of the naming of value is one of the changes that Marx made to the First Edition of *Capital*. In the latter, the naming of 'value' occurs *before* discovering its content as 'congealed abstract labour' (see Marx 1976e, p. 9). As Fitzsimons (2012, p. 25) notes, the introduction of specific terms *after* the content of their respective determina-

ary literature on Marx's theory of the value form, I think that the (analytic) search for the specific determinations of the commodity – Marx's stated aim in Chapter 1, according to the quote above – is evidently not achieved with the discovery of abstract labour as the substance of value.[42] Quite to the contrary, that very specificity seemed to have slipped through Marx's fingers. In effect, although he found the specific attribute of the commodity in its value, when he moved to account for its substance he ended up with something which bears

---

tions has been unfolded is an aspect of Marx's exposition that recurs throughout *Capital*. This presentational strategy is underpinned by a substantive methodological issue that sets apart dialectics from representational thought. Whereas the latter starts out from 'concepts' or 'categories' (i.e. purely ideal or mental abstractions) and their definitions, in dialectical science definitions do not *determine* in advance the content of a term and therefore cannot be the point of departure of the exposition. Instead, they only encapsulate determinations that have already been laboriously *developed*. In other words, definitions are arrived at rather than departed from.

[42] As a reaction to the ahistorical, Ricardian reading of Marx's account of the value form, the 'new consensus' tends to see abstract labour as a purely historical, specific social form. See, among others, De Angelis 1995; Postone 1996; Reuten 1993; Arthur 2001b; Bellofiore and Finelli 1998; Kay 1999; Saad-Filho 1997; Mohun and Himmelweit 1978; de Vroey 1982; Eldred and Haldon 1981; Bellofiore 2009a; Heinrich 2009; Mavroudeas 2004; McGlone and Kliman 2004; Roberts 2004. I have developed a more extended critique of this new consensus in Kicillof and Starosta (2007a and 2007b). Here I can only offer some brief remarks on this issue. As I argue below, abstract labour is a generic material form, a 'productive expenditure of human brains, muscles, nerves, hands etc.' (Marx 1976g, p. 134). What is specific to capitalist society is the role it plays by being determined as the substance of the most abstract form of objectified social mediation, namely, value. Murray (2000) comes very close to recognising this through the distinction between 'physiological' abstract labour and 'practically abstract' labour. A proper discussion of Murray's own solution to what he terms 'Rubin's dilemma' exceeds the scope of this chapter. Here I would only like to note that Murray's merit is to grasp the importance of highlighting the *materiality* of abstract labour while making clear that this does not necessarily lead to an asocial perspective on the value form. In this way, his recent contribution to the debate provides a necessary correction to what I see as a formalist overreaction of much recent theorising on the value form. See also Reuten's reply to Murray (Reuten 2000) and the latter's rejoinder (Murray 2002). Whilst still seeing abstract labour as capital-specific, Robles Báez (2004) offers probably one of most interesting treatments of the *movement of the contradiction* between the generic, physiological materiality of abstract labour and its historically specific *social* determination as the substance of value deriving from the private character of labour in capitalism. See also Carchedi (2009 and 2011a, pp. 60–74) for a similar argument. The debate on the nature of abstract labour has not been settled and has continued in more recent times. See Bonefeld 2010b and 2011a; Carchedi 2011b; Kicillof and Starosta 2011.

no specifically capitalist character: 'merely congealed quantities of homogeneous human labour, i.e. of human labour power expended without regard to the form of its expenditure'.[43] But it is evident that in any form of society, human beings objectified their subjective labour power and that that process of objectification entailed both a concrete or particular character and an abstract or general one. Thus far, then, this stage of the analytic process does *not* show *why* this generic materiality takes the objectified social form of value. It does not even tell us *what* is the historical form of social labour which is determined as value-producing. It *only* tells us *what* is the *material* determination of that which in capitalist society is *socially* represented in the form of value. This is the reason why Marx still carries on with the analytic search for the '*formal determinants* that it contains as a commodity and which stamp it as a commodity'.[44] This leads Marx's dialectical analysis to give closer scrutiny to the labour that produces commodities. As any attentive reader could tell, the analytic process continues and only in the section on the dual character of labour does Marx finally find the historically specific form of social labour that produces commodities and, hence, value.

In effect, Marx observes that the individual commodity he is analysing is only one among many within a totality of different commodities. But the same follows for the particular labours that underlie the varied use values taking the commodity form. In other words, Marx points out that generalised commodity production presupposes the existence of an extended social division of labour and that the latter, as the 'totality of varying deployments of useful labour', is an 'eternal necessity of nature for the sake of mediating the material interchange between man and nature (i.e. human life)'.[45] On the other hand, this analysis also makes clear that the reverse relationship does not hold, that is, the division of labour must not necessarily take the social form of the production of commodities. The formal determination of the commodity must therefore spring from the specific social form taken by the organisation of the division of labour in our present-day society. The commodity, Marx eventually concludes, is the objectification 'of mutually independent acts of labour, performed in isolation'.[46] In other words, it is the 'labour of private individuals who work independently of each other',[47] or *private and independent labour*, which constitutes the specifically capitalist form of labour or productive activity. In this social form of the human life process, the producer has the full conscious productive capacity to control the individual character of her/his labour, but cannot recognise and organise (i.e. she/he is unconscious about) the social determinations of human individuality. Hence the inversion of those social powers into an attribute of the product of labour, namely, the value form. The analytic process completes the search for the specific determinations of the value form by revealing that the attribute of general exchangeability of the commodity springs from the abstract or general character of socially necessary *privately performed* labour materialised in it. The value form, then, becomes known in its essential determination as the *objectified or reified expression of the social character of the individual labour of private and independent producers*. Its objectivity is thus revealed to be wholly social, without an atom of 'matter' entering into it.[48]

---

The Synthetic Phase of Reproduction Proper

It is only now that the synthetic stage of the presentation begins. This consists in ideally following the realisation of the discovered potentiality immanent in the commodity. From then on, the commodity ceases to be grasped in its exteriority as an 'inert' social form – as a sheer external object – and the exposition starts to follow its self-movement as the subject of the development of those determinations – previously discovered through analysis – into its more concrete forms.[49] This is subtly indicated by Marx at the end of his discussion of the qualitative determinations of the relative form of value.

---

[48] Marx 1976g, p. 138.

[49] Iñigo Carrera 2008, p. 321. In a recent article, Arthur (2004a, pp. 41–2) also acknowledges this important aspect of Marx's presentation. However, he still maintains that Marx failed to provide in Chapter 1 an adequate explanation for the determination of abstract labour as the substance of value and should have postponed the introduction of abstract labour until the level of abstraction of the capital form. See also Arthur 2005, p. 119. The shortcoming of this view – also shared by Lapavitsas (2005) and Campbell (2013), the latter following Reichelt (2007) – is that it leads to a formalistic understanding of the value form, which obscures the very question that the latter, in its own reified way, is meant to solve: the establishment of the material unity of social labour when it takes the form of private labour (Brown 2008). This idiosyncratic separation of the form of value from its substance at the level of the commodity form had already been advanced by Itoh (1988). See Clarke (1989), for a critique of Itoh's radical separation of the theory of the form of value and the theory of the substance of value.

> We see, then, that everything our analysis of the value of commodities previously told us is repeated by the linen itself, as soon as it enters into association with another commodity, the coat. Only it reveals its thoughts in a language with which it alone is familiar, the language of commodities. In order to tell us that labour creates its own value in its abstract quality of being human labour, it says that the coat, in so far as it counts as its equal, i.e. is value, consists of the same labour as it does itself. In order to inform us that its sublime objectivity as value differs from its stiff and starchy existence as a body, it says that value has the appearance of a coat, and consequently that in so far as the linen itself is an object of value [*Wertding*], it and the coat are as like as two peas.[50]

The unfolding of this movement spoken 'in the language of commodities' is precisely what the subsequent synthetic stage of the presentation consists of. Being a *purely social* power of the commodity, value cannot be immediately expressed in its sensuous corporeal materiality. As the capacity of the commodity to be exchanged for other different commodities, value can only be manifested in the social relation between commodities. Therefore, the value of a commodity necessarily expresses itself only in the use value of the commodity that is exchanged for the commodity in question as its equivalent. In this way, value takes the concrete shape of exchange value as its necessary form of appearance. In its most developed form, value acquires independent existence as money and the expression of value in the particular commodity acting as money becomes determined as price. The opposition inherent in the commodity is thus externalised through the doubling of the commodity form into ordinary commodities and money. The power of direct exchangeability of commodities negates itself as such to become affirmed as a social power monopolised by the money form.

It is in the course of the synthetic movement of this development, when seen from the point of view of its *qualitative content*, that the answer to the 'why' questions which the analytic stage was unable to provide is given. In other words, it is the development of the expression of value that unfolds the explanation as to why the objectification of the abstract character of privately performed labour takes the social form of value or, to put it differently, why private labour is value-producing.

In a nutshell, the issue comes down to the fact that it is only the expression of value that progressively reveals to us the problem that the commodity form of the product of labour is meant to solve. I am referring to the mediation in the establishment of the unity of social labour when performed in a private and independent manner. And since this unity becomes condensed in the money form, it is the unfolding of its determinations, synthesised in the peculiarities of the equivalent form and derived from its general determination as the form of immediate exchangeability, that provides the answer to the question as to why private labour must produce value.[51]

---

[50] Marx 1976g, pp. 143–4.

As the other side of its two-step analytic discovery, the synthetic ideal reproduction of the determinations of the value form comprises two aspects, each one corresponding, respectively, to the second and third peculiarities of the equivalent form. The first one – whereby the concrete labour that produces the particular commodity acting as general equivalent becomes the form of manifestation of the general character of human labour – shows, precisely, why that material expenditure of labour power has to act as the social form of labour, i.e. why it is that *abstract* labour is the substance of value. The second one – whereby the private labour that produces the equivalent commodity becomes the immediate incarnation of directly social labour – in turn makes it evident why private labour must produce value at all.

---

[51] In the Second Edition of *Capital* and the 'Value form' appendix to the First Edition, Marx develops all the peculiarities of the equivalent form as part of his discussion of the *simple* form of value. By contrast, in the First Edition, the second and third peculiarities are developed in the context of the 'reversed' form of the expanded form of value, an intermediate step which Marx did not include in the Second Edition, where he directly jumped from the expanded form of value to the general form. I think that, for my purpose here, the presentation of the First Edition is clearer. In effect, as Marx himself notes (Marx 1976e, p. 26), the solution to the problem at stake (the establishment of the unity of social labour) is revealed only when the expression of value acquires its plenitude as the form of general exchangeability by relating through the value form the universe of all existing commodities. This only occurs with the general form of value (although a defective – because it is not unified – manifestation, is already found in the expanded form). That is why I shall follow the presentation of the First Edition. On the other hand, there might be a strong reason why Marx decided to move the peculiarities of the equivalent form to the simple expression of value. In a nutshell, the point is that for the presentation of the unfolding of the specific content of the *qualitative* determination involved in the expression of value, its simple form suffices. That is why Marx states that 'the whole mystery of the form of value lies hidden in this simple form' (Marx 1976g, p. 139). The *further* formal unfolding of the more developed expressions of value only entails *quantitative* differences within that very same *qualitative determination* (Iñigo Carrera 2013). Certainly, that purely *formal* construction *helps* the comprehension of the qualitative determination entailed in the form of value by making explicit aspects of the former which are not *immediately visible* in the simple form. But no novel *quality* is unfolded. In this sense, and contrary to the claims of some scholars (Robles Báez 1997), the expansion and inversion of the simple form of value does not entail, properly speaking, any 'dialectical' or immanent self-movement. It is only a wholly formal (hence extrinsic) *representation*, which involves a *quantitative generalisation* of the qualitative determination already *fully realised* in the simple form. Incidentally, this illustrates what is the role of *formal logic* within dialectical knowledge, namely, the *representation* of the (necessarily external) determinations of quantity, that is, of 'difference determined as indifference' (Iñigo Carrera 2008, pp. 269–70). In the words of Hegel, 'a being that is indifferent with regard to determinacy' (Hegel 1991, p. 157).

In effect, through the general expression of value, all commodities relate to each other as possessing an identical social essence as exchangeable things in the same magnitude. In other words, albeit in a mediated form that reflects their social form of value as the immediate attribute of the general equivalent, their social relation of general exchangeability achieves its unity. But since they are only values as expressions of the same common social substance, i.e. abstract labour, the unity of the expression of value puts us before the unity of *undifferentiated* human labour. In determining the concrete labour that produced the equivalent as the immediate mode of appearance of abstract human labour, now the social relation between commodities itself makes plain that the different concrete labours that produced them are but different ways in which the total labour power of society has been expended. Those varied useful labours now show themselves to be what they actually are: differentiations of the expenditure of human labour power or determinate modes in which the human body has been productively exerted. In this 'roundabout way', as Marx puts it, the development of exchange value confronts us with the generic problem that any society must confront, namely, *the social regulation of the differentiation of human labour*, which 'is capable of receiving each and every determination … but is undetermined just in and for itself',[52] and which is necessary for the reproduction of human life. The exposition of the dialectical analysis of the commodity had already discovered that a commodity-producing society presupposed an extended division of labour. Now we can see that the materialised social relation itself – the value form – *affirms itself as the mediator* in the articulation of that division of labour, i.e. in establishing the relation between different labours as organic specifications of human labour in general.

> As *values* the commodities *are* expressions of the *same unity*, of abstract human labour. In the form of *exchange value* they *appear* to one another

---

[52] Marx 1976e, p. 20.

> *as values and relate* themselves to one another *as values*. They thereby relate themselves at the same time to abstract labour as their *common social substance*. Their *social relationship* consists exclusively in counting with respect to one another as expressions of this social substance of theirs which differs only quantitatively, but which is qualitatively equal and hence replaceable and interchangeable with one another … It is only the kind of thing that can turn mere objects of use into *commodities* and hence into a *social* rapport. But this is just what *value* is. The *form* in which the commodities *count* to one another as values – as coagulations of human labour – is consequently their *social form*.[53]

The necessity of abstract labour as the substance of value thus becomes finally unfolded. Abstract labour is the substance of value not because a logical argument says that it is the common property of commodities we were searching for in the name of sound principles of logic. Abstract labour becomes determined as the substance of value because *in reality* the latter is the objectified social form that mediates the organisation of that purely material expenditure of the human body into its different concrete forms across society. Given that the latter is what the value form mediates, what else could be represented in that objectified form? On the other hand, it is self-evident that abstract labour does not cease to be a generic material form because of this determination as the substance of value. Hence, as stated above, the determination of labour as abstract labour is not the reason behind its existence as value-producing labour. What is specific to capitalist society is that this purely material form negates itself as simply such so as to become affirmed as the producer of the (objectified) general social relation.[54] Once objectified, the generic *materiality* of the abstract character of labour plays a particular social role in the process of social metabolism by being represented as the *social objectivity of value*.

> The commodities' social form is their relationship to one another as *equal labour*; hence – since the equality of *toto coelo* [utterly] different labours can only consist in an *abstraction from their inequality* – their relationship to one another as *human labour* in general: expenditures of human labour power, which is what all human labours – whatever their content or mode of operation – actually *are*. In each social form of labour, the labours of

---

[53] Marx 1976e, pp. 28–9.

[54] Kicillof and Starosta 2007a, 2007b and 2011; Iñigo Carrera 2008, pp. 340–1.

> different individuals are related to one another as human labours too, but in this case this *relating itself* counts as the *specifically social form* of the labours.[55]

To recapitulate, thus far I have discussed how the formal development of exchange value, and in particular the unfolding of the determinations of the second peculiarity of the equivalent-form, contains the account of the reason why *abstract labour* is the substance of value. What still remains to be answered is why this general material character of the expenditure of human labour power becomes *substance of value*. In other words, we have to see why human productive activity becomes determined in capitalist society as value-producing, the second step in the synthetic movement referred to above.

The answer to this question follows from the third peculiarity of the equivalent form. In effect, as the social incarnation of human labour in general, the concrete labour that produces the equivalent acquires in its immediacy the form of equality with respect to the other concrete useful labours. In this form of immediate identity with every other concrete labour, the labour that materialises in the general equivalent is *immediately social*, whilst the useful labours producing the rest of commodities remain *not-immediately social*. Thus the development of the expression of value in the form of exchange value puts us before the reason why the organisation of the division of labour must necessarily be mediated in this reified form or, what is the same, why commodity-producing labour is essentially value-producing. Although materially dependent upon one another as part of the 'primordial system of the division of labour', this irreducibly social character of *private labours* is not immediately manifested when they are actually objectified in the direct process of production. Hence, this necessary social articulation of private labours is realised through the mediation of the exchange of the products of private labour as commodities. Only at that moment is the question of whether the expenditure of the portion of social labour which each producer personifies is socially useful able to be answered. This is the reason why the social character of the privately performed individual productive activities is specifically represented as a determinate objective attribute of the products of labour: the form of their general exchangeability or their value form. The basis of this reified social mediation thus resides in the fact that the unity of social labour is manifested, as Marx puts it in the *Grundrisse*, only *post festum*, through the exchange of the products of labour.[56] Furthermore, the unity of social labour thus becomes socially represented in the form of the particular private product that the rest of commodities separate as their general equivalent and which eventually ossifies in the money form. In tracing the genesis of the latter through the ideal reproduction of the expression of value, the synthetic stage of the dialectical exposition thereby positively unfolds the determinations of that which the analytic process could only *point out*. Namely, that the value form of the product of labour is the materialised general social relation of human beings in the capitalist mode of production and, therefore, the *social subject* of the *form* taken by the social process of production of human life in this historical stage of its development.[57]

---

[55] Marx 1976e, p. 32.

Only at this juncture does Marx introduce the fundamental discussion of the fetish character of commodities. The question that immediately arises, and which is hardly addressed in the literature, is why only and precisely then? I think that the answer to this question is inseparable from the issue about the determinate content of the section on commodity fetishism and its place in the overall structure of Marx's exposition in *Capital*. The aim of the next chapter, then, is to proceed to deal with these questions. Again, I will show that only through a proper grasp of the dialectical method can the full implications and significance of Marx's account of commodity fetishism be uncovered.

---

[56] Marx 1993, p. 172.

[57] We shall see that in becoming capital, the materialised social relation of private and independent individuals is constituted as the social subject of the form *and content* of the process of production of human life.

CHAPTER 5

The Role and Place of Commodity Fetishism in Marx's Dialectical Exposition in *Capital*

Introduction

Ever since the publication of works such as Rubin's *Essays on Marx's Theory of Value*[1] or Lukács's *History and Class Consciousness*,[2] the emphasis on Marx's analysis of commodity fetishism has been a hallmark of critical traditions of Marxism. In effect, according to those traditions, commodity fetishism is the cornerstone upon which the understanding of Marx's mature works as a *critique* of political economy (as opposed to political economy or economics) depends.[3] While there is no doubt that the fetishism of commodities plays a fundamental part in Marx's critique of political economy, the question is, once we accept that premise, what are the precise meanings and implications of such a notion for the scientific comprehension of capitalist society as a whole, and, more concretely, for the proletarian political action through which the movement of capital realises its own annihilation? Here, the mere reference to the centrality of the historicity of bourgeois social forms and their fetishistic character does not suffice to grasp the critical and revolutionary nature of the critique of political economy. As I have been arguing throughout this book, the specific form of the dialectical method is fundamental in this respect. And *pace* Rubin,[4] however central to the comprehension of Marx's critique of political economy, the fetishism of commodities is *not* the basis of the determinations of the value form. On the contrary, I would like to argue that the former is a necessary development of the latter.[5] This is far from being a minor point and is actually crucial for a proper comprehension of the nature of commodity fetishism and, therefore, for the ideal reproduction of the determinations of the most general concrete forms of objectivity and subjectivity of capitalist society.

The Immediate Object of Exposition of the Section on Commodity Fetishism and Its Systematic Place and Significance

In order to clarify the issue, let me go straight to the point and pose the fundamental question which underlies the proper comprehension of the systematic place and significance of the section on commodity fetishism in the structure of Marx's presentation, namely, from the point of view of the dialectical method, what is the immediate object of the exposition in that section? As Iñigo Carrera points out,[6] those pages fundamentally develop the determinations of the alienated consciousness of the commodity producer. Or, better stated, they unfold the determinations of the alienated consciousness as such, which, therefore, becomes *explicitly expounded* as an alienated consciousness. This is because, in reality, the whole of Chapter 1 (and, actually, the whole of *Capital*) has as its object the alienated consciousness of the commodity producer. However, the text starts out not with the alienated consciousness in and for itself, but with its most general *objectified* form of existence, namely, the commodity. Although the commodity *will prove to be* the alienated consciousness of the commodity producer, it is not yet known to be such at the beginning of the dialectical presentation. The commodity, not its producer, is thus the immediate subject of the determinations unfolded in the first three sections of Chapter 1.

Conversely, in the section on commodity fetishism, Marx turns his attention to the reasons why the products of private labour appear, to the producers themselves, as bearers of those reified powers whose autonomous self-movement he ideally reproduced through the expression of value contained in the exchange relation. Having discovered behind the power of exchangeability of commodities the historically specific form in which capitalist society resolves the social organisation of the organic unity of human life, the exposition needs to explain why the producers, the actual subjects whose material reproduction is at stake, must represent that process in their consciousness in such a mystical and fetishistic form. The transition is, then, from the *formal* subject of the value determinations, i.e. the commodity, to the *material* subject, i.e. the human individual.

In this respect, it could be said that the section on commodity fetishism opens a kind of new presentational (sub)node, which, in turn, will prove to be a necessary mediation for the determinations to be unfolded in Chapter 2 on the process of exchange. This is the case insofar as the section on commodity fetishism focuses on the determinations of the consciousness of the commodity producer analytically separated from the human action it regulates in the process of exchange. In other words, it expounds the determinations of consciousness mainly with regard to its *form*. Once Marx has established the historical formal determinations of human consciousness, in Chapter 2 he can then follow the mode in which the latter moves in the realisation of the general social relation, i.e. in its unity with action as conscious practice in the sphere of circulation (which is the phase of material reproduction in which human individuals *directly* confront, albeit as 'representatives of commodities', the manifestation of the general unity of social labour *indirectly* established behind their backs).[7]

---

[6] Iñigo Carrera 2007, pp. 260–1.

As corresponds to the nodal structure of Marx's exposition, he starts the section on commodity fetishism with an immediate observation: 'A commodity appears at first sight an extremely obvious, trivial thing'.[8] However, very quickly he develops the analytic movement which brings us to the inner determinations of the commodity discovered in the previous section. In effect, Marx points out that although it immediately appears as a trivial thing, the commodity is in reality an entity full of metaphysical subtleties, a sensible/suprasensible being with the fantastic power of being transformed into another use value without even touching its materiality.[9] On the other hand, at this stage of the process of cognition, we already know where to find the source of such mysticism; it must derive from the commodity form itself, i.e. from its character as the reified mediator in the establishment of the unity of the social character of private labour. In the commodity, all the qualitative and quantitative determinations of social labour appear to the material subject of this activity as objective attributes of its product.

---

[7] And even at that level, the alienated action that personifies the realisation of the necessity of the commodity to establish an exchange relation is still abstract and is part of what Marx calls, in the *Contribution to the Critique of Political Economy*, the 'theoretical phase of circulation' of commodities, 'preparatory to real circulation' (Marx 1987a, p. 303), which can only take place once 'as a result of establishing prices, commodities have acquired the form in which they are able to enter circulation' (Marx 1987a, p. 323). By this Marx means the ideal reproduction of the determinations of the circulation of commodities which constitute the premises of its actual movement. This 'theoretical circulation' comprises Chapters 1 and 2, and the first section of 3 (the functions of measure of value and standard of prices). Only then is the actual circulation of commodities reproduced in thought, revealing the subsequent functions of money not as its preconditions, but as its concrete forms.

[8] Marx 1976g, p. 163.

[9] Marx 1976g, p. 163.

> Whence, then, arises the enigmatic character of the product of labour, as soon as it assumes the form of a commodity? Clearly, it arises from this form itself. The equality of the kinds of human labour takes on a physical form in the equal objectivity of the products of labour as values; the measure of the expenditure of human labour power by its duration takes on the form of the magnitude of the value of the products of labour; and finally the relationships between the producers, within which the social characteristics of their labours are manifested, take on the form of a social relation between the products of labour.[10]

In the passage above, Marx is simply bringing together the results reached by the ideal reproduction of the form determinations of the commodity in the previous three sections of Chapter 1. However, the dialectical exposition has so far uncovered this essential content of the commodity form purely in terms of the search for the latter's immanent social determination as an exchangeable entity. As I shall argue in more detail below, the form determinations of the commodity must now be revisited from the perspective of the human being, which in section 3 has been implicitly discovered as the actual material subject of those determinations formally carried by the product of labour. In doing so, the dialectical presentation will shed new light on that very content itself. By way of a momentary analytic 'detour' from the synthetic movement of the presentation, which penetrates further into the inner determinations of the fetishistic appearance of the commodity as an autonomous subject with the social power to establish the exchange relation, the value form is revealed as the inverted representation, in the consciousness of the human being, of the social character of her/his own activity. In other words, the commodity proves to be the alienated mode of existence of the private producer's consciousness of the immanent unity of social labour of which her/his own activity is but an organic moment. It is the transposed form in which the producers consciously experience the indirect nature of their general social relation in this mode of production, projecting it as a social power external to their own individuality.

> The mysterious character of the commodity-form consists therefore simply in the fact that the commodity reflects the social characteristics of men's own labour as objective characteristics of the products of labour themselves, as the socio-natural properties of these things. Hence it also reflects the social relation of the producers to the sum total of labour as

---

[10] Marx 1976g, p. 164.

> a social relation between objects, a relation which exists apart from and outside the producers. Through this substitution, the products of labour become commodities, sensuous things which are at the same time suprasensible or social … [The value-relation] is nothing but the definite social relation between men themselves which assumes here, for them, the fantastic form of a relation between things.[11]

Now, before proceeding with this reconstruction of Marx's further unfolding of the determinations of the alienated consciousness of the commodity producer, it is worth probing deeper into some methodological aspects of the way in which his exposition approaches the determinations discussed just above. As we will see, the peculiar structure that he gives to the presentation disrupts the fluidity of the pure synthetic ideal reproduction of the commodity form. This has several consequences that could result in a misunderstanding of the systematic sequence of form determinations by inattentive (or rather, uncritical) readers. On the one hand, and more generally, it could give the impression that the section on commodity fetishism actually has no determinate *systematic* place and significance whatsoever, simply being a 'sociological' analysis which constitutes the basis of Marx's 'theoretical political economy',[12] or a 'philosophical' excursus which strays away from the exposition of the unfolding of the 'economic' determinations of the value form.[13] On the other hand, we will see that this presentation inevitably leads to repetitions of points already made earlier on in Chapter 1, which can generate the appearance of an inverted order of presentation of certain determinations.[14]

---

[11] Marx 1976g, pp. 164–5.

[12] Rubin 1972.

[13] Balibar 2007.

[14] As far as I am aware, works coming from the 'New Dialectics' approach, which are those that emphasise the systematic dialectical structure of Marx's argument (and hence the necessity of the sequence of form determinations), tend not to discuss the precise role and place of commodity fetishism (although they obviously do highlight its fundamental importance in the critique of political economy). For an overview, see Kincaid 2008; see also Reuten and Williams 1989; Tony Smith 1990a and 1993; Arthur 2002b; Uchida 1988; and from the Uno School, see Albritton 1999 and Sekine 1997. Heinrich (2012), in his introduction to the three volumes of *Capital*, offers a very detailed and rigorous commentary of each paragraph of the section on commodity fetishism which, at least implicitly, implies the acknowledgement that there is a systematic guiding thread structuring the flow of Marx's argument. However, he does not connect the latter with the form of motion of the dialectical presentation. Furthermore, oddly enough, without offering any explicit reason, Heinrich introduces the commentary on the section on commodity fetishism after his dis-

The first point to note in this regard is that one of the particular features of Marx's presentation in the section on commodity fetishism is that, unlike the analytic passage from the form of value to its substance between sections 1 and 2,[15] or the synthetic return to the unity of that substance with its form of existence in section 3,[16] he does not *explicitly inform* the reader about the content of the presentational movement that he is undertaking (e.g. the passage from value and its monetary mode of existence to the consciousness of the commodity producer), or about the formal necessity of that step in the dialectical sequence of form determinations. However, this does not mean that there is no immanent necessity structuring the flow of the argument, as implied by Reichelt's claim that Marx tended to 'conceal' the dialectical method in the published versions of the critique of political economy (and especially in the second edition of *Capital*) in order to popularise the exposition.[17] As Iñigo Carrera points out,[18] what Marx removed from the exposition, in contrast to that of earlier manuscripts like the *Grundrisse*, are the explicit reflections on the direction that his ideal reproduction of the immanent unity of content and form of a determination should take. In fact, Iñigo Carrera continues,[19] those remarks are, strictly speaking, external to the ideal reproduction of the inner determinations of the object of cognition, which is what the dialectical method is all about. In this sense, the exposi-

---

cussion of Chapter 3 on the functions of money. This undermines his otherwise insightful attempt at showing the systematic connection between the first two chapters of Volume I. As argued in this chapter, the section on commodity fetishism is a necessary mediating link between the commodity and the action of commodity owners in the process of exchange. Still, the rigour of Heinrich's commentary markedly sets it apart from David Harvey's popularising reading in his recent *Companion to Marx's Capital* (see Harvey 2010). In this recent book, Harvey characterises the writing style of the section on commodity fetishism as 'literary … evocative and metaphoric, imaginative, playful and emotive, full of allusions and references to magic, mysteries and necromancies', which he contrasts with the 'dull accountancy style of the previous sections' (Harvey 2010, p. 38). Although probably a humorous remark in a book based on lectures to postgraduate students, that characterisation of the passage from the 'language of commodities' to the 'language of human beings' has the unintended consequence of trivialising (and thus obscuring) the systematic necessity of such a transition and, as a consequence, the significance of commodity fetishism in the dialectical development of form determinations.

[19] Iñigo Carrera 2013, pp. 65–6.

tion in the published versions of the critique of political economy could be said to be actually *improved* from the point of view of the dialectical method, since it focuses more 'purely' on the 'immanent life of the subject matter' without any alien additions. It is down to the critical reader to recognise and make explicit those formal-methodological aspects which are only implicit in Marx's presentation. By contrast, this could, of course, lead other 'inattentive' readers to think that the section on commodity fetishism has no systematic place in the dialectical presentation, however fundamental it may be in other respects.

The second issue concerns the point made above about the 'disruption' of the fluidity of the systematic ordering of form determinations, partly entailed by Marx's idiosyncratic exposition in the first chapter of *Capital*, but partly a reflection of the nature of the subject matter under consideration itself. In effect, one of the peculiar features of Marx's exposition of the determinations of the commodity form in sections 1 to 3 is that when analytically moving to the more detailed discussion of 'labour' as the human action that posits the value form (more specifically in section 2), he treats it, as it were, in a purely 'objective' fashion, simply as the source or substance of value, i.e. as the content of the attribute of general exchangeability of commodities. The consequence of this is that nothing is said at that stage about what labour generically is, namely, the specifically human form of the life process and, in that determination, the *conscious* action of the working subject. In Marx's exposition, the explicit positing of this generic determination of labour as conscious metabolic interaction with 'external' nature occurs only in Chapter 7 on the 'The Labour Process and the Valorisation Process'.[20] However, he develops the generic determination of consciousness as the form of organisation of human productive action rather one-sidedly, that is, only in relation to an abstractly presented individual character of labour without regard to its immanent social determinations.[21]

---

[20] Here I would like to argue that there is an element of flexibility in the dialectical presentation. Although overall form determinations tend to follow a 'strict' systematic sequence, there are certain aspects of the object of cognition which, in principle, could be addressed at different points of the presentation. In those cases, it is down to the researcher to judge where a particular determination fits better. An example of this is Marx's postponement of the treatment of the transfer of the value of the means of production until Chapter 8. Although there is no strict systematic necessity not to address the different roles of past and new labour in the process of value formation at the level of the commodity form (since all the determinations presupposed by that qualitative difference have been unfolded at that stage), there are formal reasons that make it more sensible to leave it until later on in the dialectical presentation. Arguably, the distinction acquires full significance in relation to the determination of the diverse elements of the labour process as modes of existence of the production of *surplus value*. Dead labour now becomes a necessary form that capital must assume in order to absorb the only direct source of its valorisation

Be that as it may, the important point for the purpose of my argument here is that in the first three sections of Chapter 1, labour as subjective activity (hence consciousness) is entirely omitted from Marx's presentation. Although no more than an 'informed guess', a plausible explanation for this is that Marx wanted to stress the *real automatism* characterising commodity production as the general social relation. For this reason, he structured his exposition purely around the movement of the commodity, that is, around the simplest form of the labour *product* and the explanation of its power of exchangeability as its historically specific objective attribute (the value form). Thus, instead of directly starting with 'individuals producing in society' as he had earlier announced in the Introduction to the *Grundrisse*,[22] in *Capital* Marx took as his point of departure the *thing* that appears as the immediate carrier of that power to establish the unity of the general social relation when the human individual does not consciously organise the latter as his/her personal attribute.[23] What follows from that starting point is the ideal reproduction of the self-movement of those form determinations, and only as a *result* of this exposition, culminating with the money form as the thing-like mode of existence of the social character of labour in capitalism, does Marx make clear that at stake here is the form in which 'individuals produce in society'. But *in the course* of the dialectical unfolding of the commodity, its producer (and hence her/his consciousness) is virtually absent. The consequence of this is that when Marx does eventually address the consciousness of the commodity producer as the immediate object of his expos-

---

(living labour), but in which its generic determination as a self-expanding magnitude is immediately negated. It becomes posited as *constant* capital in opposition to the only part that does attain self-valorisation, i.e. *variable* capital. From the perspective of the simple production of commodities, the explicit differentiation between the modalities in which the diverse functional elements of the labour process enter into the formation of value of the final product is less relevant. What fundamentally matters for the simple commodity producer is that her/his commodity's value is realised in full in order to be able to buy all the other use values she/he needs for the production of her/his life. The division of the total socially necessary labour into past and fresh new living labour expended is not of the essence.

[21] Fitzsimons 2012, pp. 43–4.

[22] Marx 1993, p. 83.

[23] Iñigo Carrera 2013, p. 68.

ition in section 4, the transition might appear as an abrupt (if not extrinsic) leap. However, my claim is that it immanently follows from the determinations discovered in section 3.

Now, regardless of Marx's 'extreme' presentational strategy of obliteration of all reference to human subjectivity in the first three sections of Chapter 1, the very 'inner life' of the subject matter precludes an earlier introduction of a fuller discussion of the form determinations of the consciousness of the commodity producer as immediate object of exposition.[24] In effect, insofar as the commodity *really is* the form taken by the general social relation in capitalist society, its content in the general social character of labour could hardly be posited until presenting its 'roundabout' manifestation through the expression of value in section 3, that is, in indissoluble unity with its necessary reified mode of social mediation. Seen from a different angle, when Marx's exposition eventually addresses (commodity-producing) labour as such in section 2, it is quite simply impossible to immanently discover the unity of the general social relation since, precisely by virtue of the private character of productive activity in this society, that general social character of production is not directly manifest as an attribute of labour in act. *A fortiori*, it is not possible at that stage to expound in and of itself the form in which commodity producers carry that social character of their individual productive activity as a form determination of their consciousness. Although the 'socially necessary' aspect of value-producing labour discovered through *analysis* already makes evident that the product must be useful for an individual other than its producer (it must be a 'social use value'), this social character is still not posited (and hence fully discovered) as entailing the *general unity* of the process of human metabolism as whole. True, Marx does discover in section 2 that the existence of the commodity he is analysing presupposes a *generalised* social division of labour (yet the latter is not the 'consequence of propensity to truck, barter and exchange', as Adam Smith argued in Chapter 2 of *The Wealth of Nations*). However, this analytical discovery is reached by *representational* means when facing the concrete character of labour;[25] more concretely, by the external observation that

---

[24] This is valid, of course, if one wants firmly and strictly to remain true to the ideal reproduction of the object. However, the dialectical researcher could decide, for didactic and pedagogic reasons, to introduce remarks which are external to the real movement at stake, but which might help readers who will most likely be used to representational thought but unfamiliar with the form of motion of the dialectical method. In other words, there is a trade-off between rigour and 'reader friendliness' in a context where dialectical cognition is not yet the general form of scientific thought.

[25] Iñigo Carrera 2007, p. 229.

> the totality of heterogeneous use-values or physical commodities reflects a totality of similarly heterogeneous forms of useful labour, which differ in order; genus, species and variety: in short, a social division of labour.[26]

In other words, Marx simply points to the seemingly unconnected collection of different concrete labours which comprise social production. In turn, the specificity of the contemporary form of social mediation of the division of labour is discovered by an equally extrinsic comparison of commodity-producing society with pre-capitalist forms of organisation social life, showing that the division of labour is 'common' to both and hence a generic determination that does not explain the historicity of value production. At most, then, the initial analytical encounter with 'labour', resulting from the search for the substance of value, could present the determination of consciousness as the human form of organising the one-sidedly individual character of productive activity. This would then reveal that, in the organisation of her/his privately undertaken process of production, the consciousness and will of the commodity producer is not directly subordinated to any other consciousness and will that could tell him/her how to allocate her/his labour power in a determinate concrete form. In other words, the productive consciousness of the commodity producer would be grasped as being in full control over the *individual* character of labour. However, nothing could be said at that stage of the presentation about the way in which that productive consciousness mediates the organisation of the insertion of that singular productive action into the system of the social division of labour, i.e. about the social character of individual labour.[27]

In sum, an exposition that rigorously sticks to the ideal reproduction of the object can address the form determinations of the consciousness of the commodity producer only after facing the unity of the general social relation. The latter can be firstly discovered only as 'spoken in the language of commodities' (i.e. through the expression of the value content in the form of exchange value) and not directly as a personal determination of the human individual. However, once that point in the dialectical exposition of the commodity has been reached (now *known*, in its money form, as the immediate carrier of the unity of the general social relation of production), its own immanent development demands that the presentation veers toward the explicit scrutiny of the consciousness of the producer as its immediate subject matter.

---

[26] Marx 1976g, p. 132.

[27] An earlier introduction of the subjectivity of the commodity producer along the lines suggested above can be found in Iñigo Carrera's alternative exposition of the commodity (see Iñigo Carrera 2007, pp. 33–4). The advantage of this presentational strategy is that it allows a smoother transition between the form of value and commodity fetishism, since by the beginning of section 4 consciousness is already there confronting its own social determinations in the autonomous shapes of the commodity and money forms. The downside is that it 'spoils' the strategy of making the presentation reflect more starkly the objective automatism of the organisation of the process of social metabolism through the commodity form.

Now, in this passage, the exposition will inevitably have to retrace some of its steps and reconsider 'commodity-producing labour'. However, in this new take on its determinations, labour can be immediately grasped in the unity of its individual and general social character *and* 'spoken in the language of human beings', that is, as their *conscious* socially determined individual life activity. It is this reconsideration of labour as human action which, as anticipated above, allows the exposition to throw new light on the *content* of the value form. For, as we have seen, the latter is thus revealed not simply as the thing-like representation of the social character of privately undertaken labour. Additionally, it can now be recognised as a form of objectivity which is unconsciously projected by human consciousness itself when regulating such a privately performed productive action. Value becomes known as the mode of existence of the alienated consciousness of the private producer, a 'socially valid', therefore objective, form of thought.[28]

Note, however, that from the point of view of the formal structure of presentation, this reconsideration of the content of value, even if necessary, entails an instance of diversion from the synthetic progress of dialectical development. It is the 'analytic detour' in Marx's presentation to which I referred above, and that takes the reader from value/money back to privately organised social labour (now explicitly posited as mediated by consciousness). Once this analytic deepening of the content of value is exhausted, the dialectical presentation must obviously resume the synthetic movement of reproduction from the prior point at which the analysis culminated, namely, the discovery of value as the alienated form in which the consciousness of the private producer organises her/his individual participation in the process of social metabolism in its unity. But this obviously implies an unavoidable element of repetition of the passage over the synthetic sequence from 'private labour' to 'value'. As I shall argue below, it is precisely those passages from Marx's discussion of commodity fetishism which constitute the textual source of the rather widespread but mistaken reading that considers that section as mainly providing the explanation of why private labour must take the value form of its product. In order to clarify this point, let us return to the more detailed reconstruction of Marx's systematic argument in the fourth section of Chapter 1.

---

[28] Marx 1976g, p. 169. On the connection between commodity form and consciousness, see the detailed discussion in Fitzsimons (2012). Reichelt (2007) also provides insightful reflections on value objectivity as 'unconsciously posited by an act of consciousness'.

The Determinations of the Alienated Form Taken by the Productive Consciousness of the Private Individual

My methodologically minded reading of the section on commodity fetishism has so far reached the point at which Marx's exposition analytically discovers the alienated consciousness of the (private) producer behind the commodity form of the product of labour. The limits of this analytic discovery of the alienated consciousness for the further progress of the dialectical investigation are formally analogous to those experienced by the search for the content of the exchangeability of the commodity in sections 1 and 2 of Chapter 1 of *Capital*. As a reflection of the general role of the phase of analysis in the dialectical method discussed in the previous chapters, it can only account for the 'what' of the phenomenon under scrutiny, but is incapable of offering an explanation of its determinate 'why'. Specifically, the analysis of the commodity form from the perspective of the human being as the material subject of social labour can shed light on what the fetish-like character of the product is: the inverted representation of the social determinations of individual labour in the form of value. But this raises the question as to why the consciousness of the human being must experience her/his own immanent determinations in such an alienated form. As follows from Marx's materialist standpoint, this fetishised form of consciousness can have no other basis than the historical form taken by social being in capitalism, that is, the 'specific social character of the labour which produces' commodities, namely, private labour: 'Objects of utility become commodities only because they are the products of the labour of private individuals who work independently of each other'.[29]

The explanation of the necessity of the alienated consciousness of the commodity producer must therefore lie in the ideal reproduction of the form in which the social character of private labour asserts itself through the exchange of commodities. Having reached that point, Marx's exposition thus resumes, in the rest of the sixth paragraph of section 4, the synthetic unfolding of the movement of the unity of the general social relation mediated by the commodity form. However, unlike the earlier account in section 3 on the 'Value form, or exchange value', the dialectical development can now explicitly posit the indirect form in which social labour attains unity from the perspective of the conscious practical activity of private individuals.

---

[29] Marx 1976g, p. 165.

> The sum total of the labour of these private individuals forms the aggregate labour of society. Since the producers do not come into social contact until they exchange the products of their labour, the specific social characteristics of their private labours appear only within this exchange. In other words, the labour of the private individual manifests itself as an element of the total labour of society only through the relations which the act of exchange establishes between the products, and, through their mediation, between the producers. To the producers, therefore, the social relations between their private labours appear as what they are, i.e. they do not appear as direct social relations between persons in their work, but rather as material [*dinglich*] relations between persons and social relations between things.[30]

Marx's presentation thus finally unfolds the necessity of the alienated consciousness of the commodity producer. As a private and independent human being, the producer is incapable of recognising that her/his productive action possesses social determinations that transcend the immediacy of its singularity. Consequently, when organising the expenditure of the labour power that she/he embodies, the consciousness of the human individual must project or transpose – hence confront – those individually borne social powers as external to her/his individuality and existing as the objective attribute of the product, which allows it to enter the exchange relation and manifest indirectly the human subject's immanent determination as an individual organ of social labour: the form of exchangeability or the value form. In sum, the latter is the fetishised form in which the consciousness of the private producer resolves the organisation of her/his participation in the general process of social metabolism.

With this Marx expounds the determination of consciousness with regards to its most *general form* in capitalism. From this simplest determination of the consciousness of the commodity producer, he then proceeds to unfold its more concrete form of realisation in its generic condition as the human form of organising transformative action upon nature. In the first place, through the productive action that it privately regulates in the direct process of production. Thus, the producer not only faces her/his own social powers as external to her/his subjectivity and carried by the product of her/his labour in the process of exchange through which social labour attains unity. As exchange extends its role in social reproduction, the plenitude of which is reached in capitalist society where it becomes the general social relation, this inverted consciousness starts to regulate the direct production process itself. Under those circumstances, already at that moment must the commodity producer put her/his consciousness at the service of social powers which she/he sees as alien to her/his subjectivity, that is, as belonging to the commodity.[31] When resolving the concrete form in which she/he will privately expend the aliquot part of the total labour power of society that she/he embodies, the social character of her/his labour already appears to the consciousness of the producer as an attribute of the product in a twofold sense.[32] Firstly, she/he must produce a use value which must satisfy the needs of other individuals with whom she/he does not have any immediate or direct social nexus. Secondly, that socially useful character of the product must be formally mediated by its determination as the bearer of the property to be transformed into any other use value, that is, the attribute of general exchangeability or the value form. Thus, at the very moment in which she/he actually exerts her/his productive subjectivity in the direct process of production, and in order to organise her/his affirmation as an individual organ of the social division of labour, the private individual must produce not only socially useful things, but also exchangeable products; she/he must posit value. In brief, the private individual must already alienate her/his productive consciousness in the commodity when acting in the immediate production process.[33]

---

[30] Marx 1976g, pp. 165–6.

---

[31] Iñigo Carrera 2007, pp. 58–9.

[32] Marx 1976g, p. 166.

[33] In this sense, value-positing is for Marx an immanent result of the direct production process and not, as Rubin and contemporary 'circulationist' value-form theorists argue, a determination of the sphere of circulation which 'leaves its imprint' on a labour process that posits value only 'mentally' or 'latently' (Rubin 1972; Reuten and Williams 1989; Heinrich 2011 and 2012). For a more detailed critique of Rubin's circulationist value-form theory and its political implications, see Kicillof and Starosta 2007a. Bonefeld (2010b), drawing on Bellofiore (2009a) and Arthur (2001b), attempts to avoid the pitfalls of Rubin's circulationist views by giving an objective character (as opposed to merely mental or

At this juncture, after having uncovered value as the reified mode of existence of the determinations of consciousness, Marx hastens to clarify that this by no means implies that the human individual is actually aware of this fact. Thus, he argues, it is not the case that commodity producers consciously recognise the determination of their private labours as individual fragments of human social labour and thereby exchange their products as equivalent materialisations of abstract labour, i.e. give them the form of value. It is the other way round. They *unconsciously* give the products of labour the form of value and, through this reified social mediation, they equalise behind their own backs their private labours as individual organs of the total labour of society on the basis of their material identity as pure expenditures of human labour power.[34] The constitution of the social objectivity of the value form, although being the spontaneous product of their own brain (hence of their consciousness), appears to the commodity producers as a *fait accompli* springing by nature from the materiality of the product of labour. In sum, the consciousness of the commodity producer, in its most general and simple form, is not only an inverted consciousness, but also an apparent one. As the bearer of that form of consciousness, the human individual is unable to recognise the necessity – i.e. the determinations – of her/his conscious action beyond the appearance of being an abstractly independent action. As the necessary 'spontaneous and natural' form in which the producer privately organises the insertion of her/his practical action into the social metabolic process as a whole, this immediate practical consciousness persists even after political economy scientifically discovers the labour content of the value form.[35]

In this sense, the corollary of Marx's discussion of commodity fetishism is that consciousness is actually torn asunder when social being takes the form of private labour. It simultaneously exists both as a form of the subject of social labour and as an objective form of its product.[36] Before continuing with the textual commentary on commodity fetishism, let us probe deeper into this fundamental point.

In its generic condition as the specifically human capacity to organise the life process, consciousness always entails a twofold determination as much as the

---

ideal) to the projection of the ghost-like objectivity of value back into production from its original constitution in exchange. For a critique of Bonefeld's position, see Kicillof and Starosta 2011.

[34] Marx 1976g, pp. 166–7.

[35] Marx 1976g, p. 167.

[36] Fitzsimons 2012, p. 37.

labouring activity that it regulates.[37] On the one hand, it is the form in which the human being rules the immediacy of the individual productive expenditure of her/his corporeal powers in order to appropriate and transform external nature into a means for human life. In this determination, consciousness is the human capacity to organise the unfolding of the individual character of labour. On the other hand, those individually borne productive powers can only be constituted socially, that is, they can only develop as a result of the productive action of other individuals (who, for instance, have participated in the production of the use values whose consumption resulted in the productive attributes borne by the former individual's labour power). Moreover, the individual labourer produces use values not solely for her/his own consumption, but for others, that is, *social* use values. Although an individual human action, labour therefore always has an intrinsically social character as well. This twofold character is borne by consciousness as its necessary form of organisation. Consciousness thereby does not simply undertake the regulation of the individual appropriation of the potentialities of external nature in order to transform it, but must also mediate the establishment of individual labour's immanent unity with the socially general metabolic process of which it is an organic part. As an attribute borne by the individuality of each human being, consciousness is thus the capacity to establish the unity of social labour through the individual productive action of each of its subjects, i.e. to regulate the social character of individual labour.

It is this twofold immanent potentiality of consciousness which is torn apart in commodity-producing society. Insofar as the private form of labour negates the capacity of human subjectivity to recognise and control the social character of its activity, that material potentiality of consciousness becomes formally alienated in the commodity. In this social determination, consciousness thereby exists in the mode of the objectivity of value. But the other side of this inversion is that, as subjective capacity, the consciousness of the commodity producer becomes determined as an abstractly individual human attribute. Only in this one-sided form does consciousness immediately exist *as consciousness*.

Based on these premises, let us now return to Marx's argument in the section on commodity fetishism. After having established the *genesis* or *social constitution* of the doubling of the consciousness of the commodity producer, Marx systematically proceeds to unfold the concrete form in which this abstractly individual practical subjectivity apprehends the alienated mode of existence of its social determinations as an *already constituted objective form*. More specifically, the immediate practical consciousness of the commodity producer ideally represents the movement of her/his alienated social being in the form of an estimate of the proportions in which her/his commodities will exchange for the other commodities she/he needs. Thus, Marx comments:

---

[37] Fitzsimons 2012, pp. 44–6; Iñigo Carrera 2007, pp. 43–9.

> What initially concerns producers in practice when they make an exchange is how much of some other product they get for their own; in what proportions can the products be exchanged?[38]

Now, insofar as consciousness is but the organisation of human action, the next systematic step after presenting the *form* in which the private producer represents 'in her/his head' the value determinations in a constituted form, must consist in expounding the way in which this practical subjectivity productively *acts* on this basis in order to take part in the system of all-round material interdependence characterising generalised commodity production. When faced with the movement of the unity of their social life process in a form that escapes their own individual potentialities, human beings are condemned to act, in Reichelt's eloquent formulation, as

> executors of constraints generated and reproduced by themselves, which are implemented in and through their conscious actions without, however, being consciously accessible to them.[39]

At stake here, then, is the *autonomisation* of the general social relation from the conscious control of individuals and the consequent real appearance or 'objective illusion' of *automatism* characterising capitalistic production.

As Marx argues, this determination of the practical action of private individuals becomes firmly established only when the movement of the quantitative articulation of the social division of labour becomes regulated by the magnitude of value.[40] This is because the degree in which the products of labour are exchangeable starts to vary independently of the producer's individual consciousness and will. Hence, in order to satisfy her/his qualitatively and quantitatively determined needs – thereby reproducing her/his natural life – the producer cannot but determine her/his consciousness and will as the servants of the capricious changes of the magnitude of value of the commodity she/he produces, which varies 'continually, independently of the will, foreknowledge and actions of the exchangers'.[41] In other words, she/he not only faces her/his own social determinations as alien powers borne by the product of labour, but the latter comes to control the producer herself/himself. As Iñigo Carrera succinctly puts it,[42] the commodity producer can reproduce herself/himself as a *person* only by acting as the most abject *personification* of the commodity.[43]

---

[38] Marx 1976g, p. 167.

[39] Reichelt 2007, p. 5.

[40] Marx 1976g, p. 167.

With this characterisation of the practical subjectivity of human beings as personifications of the movement of the value form, Marx's exposition completes the ideal reproduction of the simplest social determinations of the alienated consciousness of the private individual and its concrete forms in the sphere of production. From the point of view of the formal structure of the dialectical presentation, the important point to bring out is the precise sequence of form determinations that guides the flow of Marx's argument, which I will now formally sketch out.

As I have shown in the previous section, Marx's exposition firstly moves analytically in order to discover the alienated consciousness of the commodity producer behind the value form and private labour as the foundation of the former. From that point onwards, he undertakes again the synthetic return journey from private labour to value, albeit now as mediated by consciousness, thereby accounting for the 'why' of the latter's alienated mode of existence in the commodity. In this phase of his argument, the unfolding of novel form determinations concerning the inner connection between consciousness and value inevitably overlaps with repetitions of points made earlier about the inner connection between private labour and value. After moving from human subjectivity to its transposed form of existence in the objectivity of value, Marx turns his attention back to the material subject of social labour in order to uncover the form of this consciousness which, in its immediacy, appears as abstracted from its social determinations. It is here that, strictly speaking, the presentation of entirely new content actually starts to unfold. The exposition thus reveals the sundering of the immanent twofold determination of human productive consciousness (individual and social) into an abstractly individual attribute of the material subject of social labour and the objectified mode of existence of its social determinations in the commodity, the latter being posited by the spontaneous or unconscious act of consciousness itself. What follows is the development of the concrete form in which the private producers ideally reflect on those social determinations, grasping them in their immediacy as already existing forms of human life. On the basis of these immediate appearances, they organise their alienated practical action in order to reproduce the materiality of their lives, thereby becoming determined as personifications of the autonomised self-movement of those objectified forms of social mediation. Note in this regard that this means that the relation between consciousness and value suffers, as it were, a reversal. If, at the beginning, value appeared as the self-negating mode of existence of consciousness, the exposition later reveals that human subjectivity and its conscious practical action actually develop into a concrete form of the self-movement of the value form. One could argue that in this way Marx eventually justifies his presentational strategy of total obliteration of subjectivity when structuring the argument in the first three sections of Chapter 1 in apparently 'objectivistic' terms around the explanation of the exchangeability of the commodity as such: the establishment of the unity of capitalist social production proves to be predicated on a real automatism and not on the conscious knowing and willing of the material subject of social labour.

---

[41] Ibid.

[42] Iñigo Carrera 2008, pp. 11–12.

[43] The rest of the section in Chapter 1 of *Capital* deals with the *ideological* scientific form of the alienated consciousness of the modern individual (political economy) and with general comments on other social forms and their respective forms of social consciousness. The latter are external observations in the dialectical presentation which evidently play a didactic or pedagogical role by helping to emphasise the specificity of capitalist social forms.

With all this in mind, we can now take stock of the precise systematic place and significance of the section on commodity fetishism in Marx's order of presentation. Inasmuch as it has the consciousness of the commodity producer as its immediate object of exposition, it can only appear *after* the analytic and synthetic development of the determinations of the value form. The reason for this is that the determinations unfolded in the former are nothing more than the forms in which the latter concretely develop. To put it plainly, *the individual consciousness of the commodity producer is a concrete form in which the commodity, as the formal subject of the process of human metabolism, realises its own determinations*.

The full significance of this order of determination can be better appreciated in Chapter 2, in which, as anticipated above, Marx presents that alienated consciousness in motion, effectively acting as personification of her/his commodity in the sphere of exchange, that is, in the phase of the social reproduction process in which the unity of the social character of labour becomes manifest through a direct relation between human beings (i.e. the voluntary contract). In other words, when he presents the process of exchange as the concrete realisation of the social relation materialised in the commodity. After analytically penetrating the immediate appearance that it is the human individual who consciously and voluntarily controls the product of labour, Marx sets out to unfold the realisation of the essential determination with which the previous section finished, namely, in capitalist society,

> the characters who appear on the economic stage are merely personifications of economic relations: it is as the bearers of these economic relations that they come into contact with each other.[44]

What follows, then, is the alienated action of individuals determined as personifications who, through their unconsciously organised social action, cannot help manifesting by way of their 'natural instinct' the 'natural laws of the commodity' discovered in Chapter 1.[45] In effect, out of the development of the exchange process necessarily crystallises the money form of the commodity. The value form of the product of labour affirms itself as an abstract form through its self-negation, that is, by realising its own necessity in the form of the atomistic action of commodity owners, which act as vehicles for the realisation of the 'will' of their commodities.[46] Hence the importance of not only grasping the unity between the section on commodity fetishism and the rest of Chapter 1, but also accounting for the crucial presentational unity between the latter as a whole and Chapter 2.

As the ideal reproduction of these real relations among forms of different levels of abstraction, the dialectical presentation cannot posit the fetishism of commodities – i.e. the inverted self-consciousness of the commodity producer and its determination as personification of the value form – prior to the unfolding of the social relations whose unity is ideally mediated in that historical form of consciousness. If it did so, it would, like it or not, fall prey to the idealist inversion of positing consciousness as taking concrete form in social being. And since the times of *The German Ideology*, Marx and Engels had made clear that such a way of conceiving of the relation between social being and forms of consciousness entailed turning the real relations upside down. Maybe aware of the risk that his own exposition might be read in that inverted fashion, Marx in the first edition of *Capital* explicitly stated the order of the relation:

---

[44] Marx 1976g, p. 179.

[45] Marx 1976g, p. 180.

[46] Arthur correctly points this out (see Arthur 2004a, pp. 37–8). Heinrich also brings out this issue in distinguishing between Marx's exposition of the 'economic determinate form' and the 'activity of commodity owners' (see Heinrich 2012, pp. 72–9).

> First their relationship exists in a practical mode. Second, however, their relationship exists as relationship for them. The way in which it exists for them or is reflected in their brain arises from the very nature of the relationship.[47]

In order to highlight the importance of this, let us briefly discuss Rubin's claim that the account of commodity fetishism constitutes the 'propaedeutic' to, and basis of, the determinations of the value form.[48] In a nutshell, Rubin considers that the content of the section on fetishism is what, as I have argued above, in reality corresponds to section 3 on the form of value or exchange value, i.e. the synthetic exposition of the reason why the product of labour must take on the value form. And this confusion should come as no surprise, since, as I have already pointed out, Marx's exposition itself contains elements for an inattentive reader to be led to these mistaken conclusions. In effect, we have seen that Marx interjects as part of the development of the alienated consciousness as such *repetitions* of arguments he had already developed when he was effectively presenting the determinations of the commodity as the general social relation (the objectified social being, so to speak). That many of those passages just reinstate points already made earlier is evidenced by the way in which Marx introduces them:

> *As the foregoing analysis has already demonstrated*, this fetishism of the world of commodities arises from the peculiar social character of the labour which produces them.[49]

Now, regardless of the ambiguities in Marx's presentation, it is not there that the basis for Rubin's confusion is to be found. The problem resides, in reality, in Rubin's inadequate comprehension of the dialectical structure of the exposition in Chapter 1 of *Capital*. As we have seen, the place where Marx unfolds the synthetic movement from (private) labour to value is not in the fourth section which, in broad systematic outline, corresponds to the synthetic movement leading from value to consciousness, albeit necessarily retracing some steps in order to discuss the social determinations of the productive consciousness of the commodity producer, but in section three on 'The form of value or exchange value' (in which, as I have argued, the sequence from private labour to value is unfolded in the 'language of commodities', that is, in unity with that which leads from value to exchange value/money). And yet in Rubin's scheme of things, this latter section plays no fundamental part. Why? Because, for him, section 3 of the first chapter contains a *purely formal* development that simply illustrates the different forms of exchange value as modes of expression of value. In Rubin's view, there is nothing about the qualitative content that is affirming itself through self-negation in the mode of that formal development.[50] So much so that in the 275 pages of his book on the theory of value, the formal development of exchange value only deserves some comments in passing[51] and a couple of footnotes.[52] In these places, moreover, Rubin only mentions the development of exchange value to state that he will not occupy himself with the form of value, only with value as form.[53] No wonder, then, that when he later in the book finds those repetitions of the synthetic movement from private labour to value in the section on commodity fetishism, he is led to think that that development appears for the first time there and, therefore, constitutes its fundamental content.[54]

---

[47] Marx 1976e, p. 36.

[48] Rubin 1972, pp. 6, 61.

[49] Marx 1976g, p. 165, my emphasis. Heinrich also notes that with that introductory line Marx refers to the content of the previous sections (Heinrich 2011, p. 176).

---

[50] This is how Rubin comments on the content of section 3 of Chapter 1: 'Marx himself mentions "the form of value" in various passages incidentally. The third section of Chapter 1 of *Capital* has the title "The Form of Value or Exchange Value". But Marx does not remain on the explanation of the form of value, and quickly passes to its various modifications, to the individual "forms of value": accidental, expanded, general and monetary' (Rubin 1972, p. 114). Thus, the precise place where Marx unfolds in great detail the explanation of the reason to be of value is taken by Rubin as containing no more than a merely 'incidental' brief passage on value as social form.

[51] See, for example, Rubin 1972, pp. 122–3.

[52] Rubin 1972, pp. 68, 112.

[53] If section three only contains a non-fundamental formal development, one wonders, then, why did Marx introduce in the first edition an appendix on the form of value? Besides, had Rubin paid attention to that appendix, he would have noticed that insofar as the section on commodity fetishism is a concrete form of the development of the form of value, Marx introduced the former discussion as the fourth peculiarity of the equivalent form (Marx 1976e, p. 59). The point about the place of commodity fetishism in the appendix to the first edition has also been noted in passing by Arthur (2009).

[54] And where exactly does Rubin find a 'detailed elaboration' of the value form? For instance, in a footnote, specifically, number 34 in the Penguin edition of *Capital* (Rubin 1972, p. 114). Now, by definition, a footnote can hardly contain the elaboration of the essential content of a form determination. Furthermore, in that particular footnote, Marx is unambiguously commenting on the ideological and apologetic character of the science of political economy (for falling prey to the fetish-like character of the commodity), and is not, by any stretch of the imagination, 'elaborating in greater detail' on the determinations of the value form.

What are the implications of this misreading, so influential among contemporary followers of Marx? In a nutshell, a conception of Marx's critique of political economy, and in particular of the section on commodity fetishism, one-sidedly determined as an exposition of the social constitution of the forms of objectivity of capitalist society. The transposed relation between human practical activity and its objectified forms of social mediation is exhausted in the constitution of those forms of objectivity as a hostile alienated social power standing above and constraining human individuality. But this inversion is not followed through to its necessary unfolding in the determination of the latter as personification of the value form. This has the consequence of rendering the most general determination of human individuality in capitalism under-theorised, thus opening up the possibility of postulating an instance of exteriority between human consciousness and will (i.e. subjectivity) and the value form; the former is thus seen as not fully determined as a mode of existence of the latter. As we shall see later on, this exteriority eventually hinders the full comprehension of what a consequent dialectical development of these abstract determinations necessarily leads to, namely, the discovery of the determination of (social) capital as the concrete alienated subject of the historical movement of present-day society. To put it differently, I will show that those readings fail to follow the transition from the fetishism of commodities to the fetishism of capital, that is, from its abstract determination as a formal inversion between subject and product of social labour up to its full transformation into a complete real inversion. I shall leave this aside for the moment, since it will be the topic of later chapters. In the next chapter, I return to the discussion of commodity fetishism in order to probe deeper into the concrete forms taken by the alienated subjectivity of the commodity producer.

CHAPTER 6

The Commodity Form, Subjectivity and the Practical Nature of Defetishising Critique

Introduction

As we have seen above, the historical specificity of the commodity form of social relations resides in the constitution of private and independent production as the mode of existence of social labour. This, I have argued, constitutes the ground of the historical determination of productive labour as value-producing. The commodity producer is condemned to see the social determinations of her/his activity as an objective attribute of the product of labour. Thus far, then, the determinations of the alienated consciousness of the commodity producer have been reconstructed on the basis of Marx's explicit account of commodity fetishism. The question that needs to be addressed now is the following: how must this private producer, who has projected her/his social powers as the value form of the product of labour, see herself/himself in order to effectively act as the personification of her/his commodity? In other words, if the commodity form is the *objective* form of existence of the alienated consciousness, what is its corresponding *subjective* form?

The answer to this question is another fundamental aspect of the determinations of alienated consciousness, which arises already at the level of the commodity form, and which, I think, even the most sophisticated readings tend to overlook.[1] Admittedly, this is not *explicitly* posed by Marx in the section

---

[1] The *programmatic* statement about the commodity form as the basis for the forms of objectivity *and subjectivity* of capitalist society can be traced back to Lukács in *History and Class Consciousness* (1971). However, the specifics of his argument, overly leaning on a romantic abstract opposition between activity and passivity, and a Weberian conception of reification as an 'iron cage', undermined his otherwise valid research programme (Starosta 2001). More recently, the research programme has been taken up by Postone (1996, pp. 36–9, 216–25, 273–7, 314–25) in a way that avoids many of Lukács's shortcomings by more consistently attempting to ground forms of subjectivity immanently and historically in the alienated movement of present-day 'structures of social mediation' (both capital-reproducing and capital-transcending forms of consciousness). See also Postone 2003. However, I think that Postone's own approach does not fully fulfil its programmatic premises (Starosta 2004). Thus, despite some references in passing to bourgeois forms of individuality (Postone 1996, pp. 32–

© KONINKLIJKE BRILL NV, LEIDEN, 2016 DOI: 10.1163/9789004306608_008

on commodity fetishism. However, it appears more clearly in the *Grundrisse* and, as far as *Capital* itself is concerned, it is scattered in different parts of Volume I.

3, 273–7), Postone fails to grasp the apparently self-determining freedom of the commodity producer as the most general subjective form taken by the realisation of her/his alienated productive subjectivity. As a consequence, he is unable to specify the concrete form taken by the consciousness that constitutes the determinate negation of freedom as the form of alienation. In fact, although he claims to ground revolutionary consciousness socially and historically, capital's intrinsic developmental dynamic as unfolded in his book only posits immanently the *possibility* for emancipatory subjectivity to emerge, by creating an internal tension between the actuality of capitalist industrial production, which is impoverishing for the many, and the historical potentialities it contains for the mode of social labour to become 'enriching' to everyone (Postone 1996, pp. 28, 34–5). But the *realisation* of that possibility is not seen by Postone as an immanent necessity engendered by the very movement of that alienated form of social mediation. Although not explicitly stated by Postone, it follows from his approach that revolutionary subjectivity must be eventually posited as abstractly free and self-determining, externally 'reacting' or 'responding' to the 'objective' contradictions of capital in the form of self-activating 'needs, demands and conceptions that point beyond capitalism' (Postone 1996, p. 37). In the end, he offers an admittedly more sophisticated version of the Classical Marxist abstract opposition between objective and subjective conditions for the abolition of capital, the former providing the external context which 'facilitates' or 'triggers' the self-development of the latter. It is more sophisticated insofar as the essential contradiction of capitalism is not represented simply as one between socialised production and private appropriation, but, following Marx's discussion of the fragment on machines in the *Grundrisse*, as a contradiction between materiality and social form intrinsic to the capitalistic form of the labour process itself (large-scale industry in particular). However, the *objectivistic* way in which he conceives of that essential contradiction – the tendential disappearance of direct labour rendering anachronistic its determination as source of value (Postone 1996, pp. 24–5) – does not allow him to see the way in which its historical development can only find 'room to move' in the form of its self-overcoming, which in turn must necessarily take the form of the revolutionary political subjectivity of the working class. Thus, Postone not only fails to see how the immanent contradictions of the capital form (the content) can only exist and develop in and through the political action of workers as a class; in addition, partly as result of a flawed reading of the qualitative determinations of the productive subjectivity of large-scale industry, he also denies the working class the determination of material bearer of the necessity to abolish capital. Instead, he postulates a socially undetermined 'people' as the subject of the 'reappropriation of socially general capacities that are not ultimately grounded in the working class and had been constituted historically in alienated form as capital' (Postone 1996, p. 357). As I shall argue later on, the key to avoiding these shortcomings consists in discovering that the essential contradiction of capitalism is immanently carried by the transformations of the qualitative determinations of the productive subjectivity of the working class. I come back to these questions in the last two chapters of the book.

Be that as it may, even if it is not *systematically* integrated by Marx into the dialectical exposition, one of key insights to be found in Iñigo Carrera's work is to have shown that it is implicit in *Capital* from the very first chapter. Indeed, I think that here lies one of Iñigo Carrera's most important contributions to the contemporary reconstruction of the Marxian critique of political economy: as he forcefully argues at great length, in capitalism free consciousness is neither the abstract opposite to nor the content of alienated consciousness, but the concrete form in which the latter affirms through its own negation.[2] In other words, the other side of the coin by which the human individual sees her/his social powers as the objective attribute of the product of social labour is her/his self-conception as the bearer of an abstractly free subjectivity. This insight will prove to have fundamental implications for the comprehension of that which, as I have been arguing, is the central aim of the scientific development of the critique of political economy, namely, the self-consciousness of the determinations of its own revolutionary subjectivity by the working class. Let us therefore subject this issue to closer scrutiny.

Free Subjectivity as Alienated Subjectivity

The development of the commodity as the general social relation presupposes the dissolution of all relations of personal dependence. The consciousness and will of the commodity producer is therefore not subordinated to any other consciousness and will in the organisation of her/his material life. In other words, seen in its immediacy (and that is the standpoint of all ideological representations of capitalist society), the consciousness of the commodity producer is *free* from subordination to the direct authority of any other individual or any other direct social relation (such as customary community or kinship relations). What is the actual meaning of this freedom when seen from the only materialist point of view, that is, from the point of view of the organisation and development of human productive subjectivity? Inasmuch as she/he is not subject to any relation of personal dependence, the private individual has the *full conscious control* over the *individual* character of her/his productive activity. The 'tragedy' of this individual is that she/he is not the only one enjoying this apparently absolute freedom. In the same vein as every other consciousness and will is completely excluded from her/his own productive decisions, she/he is absolutely incapable of having any say in the organisation of any other process of individual metabolism, the organic totality of which comprises the metabolism of society. This means not only that the commodity producer has no personal capacity to establish the concrete form in which other members of society will exert the labour power that each of them embodies. It also involves the incapacity to organise their consumption, which means that she/he has no control over the determination of the products of her/his labour as *social* use values.[3] Hence the cost at which the plenitude of this control over the individual character of labour comes, namely, the absolute lack of control over its *social* character and the consequent constitution of the value form as the reified mediator in the process of production of human life. And hence the need to put this free consciousness and will to produce an alien social power – i.e. value – in the best possible manner, as the only way to reproduce the producer's material life. The realisation of her/his freedom proves to be the concrete form taken by its inner determination as personification of the social powers of her/his commodity. In other words, her/his free consciousness is, in reality, a concrete mode of existence of an essentially alienated consciousness.[4]

---

[2] Iñigo Carrera 2007, Chapter 3.

The crucial point at this juncture is to grasp the real relation between this freedom as autonomy or self-determination and alienation beyond any externality – or inversion – between them. Thus the inverted appearance could arise that the relation between form and content of the consciousness of the private individual is such that alienation is the mode of existence of an ahistorically conceived freedom of the human subject. But my point is that the real relation consists of alienated consciousness affirming through self-negation by realising its immanent social determination in the form of free consciousness.

Perhaps I can put this important point across more clearly by briefly comparing this perspective to the one put forward by Richard Gunn who, in probably one of the most sophisticated attempts to explicitly deal with this question within Marxism, clings precisely to that inverted appearance between freedom and alienation.[5] For Gunn, the whole 'trick' that is necessary to grasp the contradictory relation between freedom and alienation in capitalist society is 'to see unfreedom as a mode of existence of freedom'.[6] Thus he claims that, in reality, there is no such thing as unfreedom, but only 'unfree freedom', which 'amounts to freedom contradicted, or to freedom subsisting alienatedly, i.e. in the mode of being denied'.[7] We shall see the practical consequences of this kind of inversion below, but for the moment let us just focus on the *methodological* dimension of this discussion and note that despite his references to dialectics being the ideal expression of the real movement, Gunn reaches these conclusions through an exemplary exercise in dialectical *logic*. He starts with an axiomatic (ontologically or transcendentally grounded?) definition of the concept of freedom as self-determination and then subjects this concept to the general *logical* necessity of 'affirming through self-negation'.

---

[3] Iñigo Carrera 2007, p. 51.

[4] In other words, from a materialist standpoint, complete freedom is neither the absence of all determination nor an abstractly individual self-determination ('doing as one pleases' in the face of '*external*' constraints). Instead, it is the self-conscious control by the human being over her/his twofold *immanent* determination (individual and social) as a working subject, that is, over her/his *individual* participation in the *intrinsically social* process of human metabolism.

[5] Gunn 1992.

In the argument presented here, by contrast, I started, paraphrasing Marx's remark in his notes on Adolph Wagner, with a 'concretum': not the universal 'concept of freedom', but the historically determined free consciousness of the commodity producer. And by concretely reproducing in thought the realisation of its *specific* material potentiality as capable of ruling the individual character of labour, but not its social character, I uncovered its actual determination as the form of the alienated consciousness, hence as personification of the value form. Only *after* concretely unfolding the movement of these social forms could one *recognise* the general form of motion as one of 'affirmation through self-negation'. But I did not justify this *specific* form determination by recourse to that *general* form of movement of the real. This, I think, illustrates the sometimes thin line separating the dialectical *method* from dialectical *logic*, already identified in Chapter 3.

Thus, it is not that this freedom as apparent 'self-determination', abstractly conceived of as a natural attribute of human beings, is negated in capitalist society by taking the form of an alienated consciousness, which is 'constrained' to produce value by the external compulsion emanating from the 'objective social context' in which the individual finds herself/himself. It is the other way round. In the material process of producing her/his life at this particular stage in the historical development of the material productive forces of society, individuals can only socially relate with each other through the production of value, i.e. as personifications of the commodity, which, in turn, produces in these individuals this free consciousness as its necessary concrete form. It is by seeing herself/himself – and therefore practically acting – as personally free that the individual reproduces the subordination to the commodity form. The affirmation of this freedom as abstract self-determination of the subject becomes determined as the concrete form of the movement of the alienation inherent in the commodity form of social relations, i.e. in private labour. The fetishistic appearances of the objective forms of the alienated consciousness are thus paralleled by the corresponding 'fetishism' of their subjective forms. We have seen the determination of the alienated consciousness of the commodity producer as an apparent consciousness that cannot recognise in value the social determinations of her/his individual productive activity, thereby seeing it as a natural attribute springing from the materiality of the product of labour. In the same vein, the commodity producer is incapable of recognising her/his free consciousness as the necessary concrete form taken by the affirmation of its alienated character, thereby seeing it as a natural attribute of human individuals springing from an anthropological determination of the species. In their unity, the value form of the product of labour and the apparently free consciousness of the producer, respectively, constitute the most general, objective and subjective forms of existence of the alienated consciousness in the capitalist mode of production.[8]

---

[6] Gunn 1992, p. 29.

[7] Ibid.

As evidenced by my reconstruction of Marx's account of commodity fetishism in Chapter 1 of the first Volume of *Capital*, his presentation of the determinations of the alienated consciousness of the commodity producer does not explicitly address its concrete form of subjectivity as free consciousness at that stage. In general, the references to the latter appear in the context of more concrete determinations, i.e. at the level of the capital form. Furthermore, only in the chapter on simple reproduction, when the plenitude of alienation is presented through the constitution of social capital as the subject even of the process of individual consumption, does Marx make the explicit point about free consciousness as the necessary form of reproduction of its alienated content.[9] At the level of the commodity form, the closest reference to this determination of free consciousness appears very briefly only in relation to its more concrete *juridical* expression at the beginning of Chapter 2. That is, it appears only in relation to commodity *owners* (as opposed to producers), in the context of the *direct* (hence conscious and voluntary) relation between two *particular* private individuals established in the process of *exchange* – the contract – through which the *general indirect* (hence unconscious) relations of commodity *production* assert themselves.[10]

---

[8] Note that the problem does not reside in the isolated or 'monadic' affirmation of this free consciousness, whose limitations would be overcome by simply assuming a directly collective mode of realisation of this very same freedom. As I argue below, the determinate negation of this apparent freedom consists in a form of consciousness which is free not for being 'self-determined', but by virtue of being conscious of its own immanent social determinations; which in this mode of production, given the latter's real inverted existence in an objectified form, can only mean being self-conscious of its own alienated nature and of the productive potentialities historically developed in such an alienated form. In other words, it also involves a *transformation* of the form of human freedom into the fully conscious knowledge of the social determinations of individual labour and, *as a consequence*, the recognition of the necessity to regulate it as a directly collective power.

In the *Grundrisse*, however, not only are the juridical forms of commodity production subject to a more detailed treatment, but in addition, Marx makes the point about this determination of free consciousness as the concrete form of the alienated consciousness without ambiguity.

> In present bourgeois society as a whole, this positing of prices and their circulation etc. appears as the surface process, beneath which, however, in the depths, entirely different processes go on, in which this apparent individual equality and liberty disappear. It is forgotten, on one side, that the *presupposition* of exchange value, as the objective basis of the whole of the system of production, already in itself implies compulsion over the individual, since his immediate product is not a product for him, but only *becomes* such in the social process, and since it *must* take on this general but nevertheless external form; and that the individual has an existence only as a producer of exchange value, hence that the whole negation

---

[9] Marx 1976g, pp. 717–19.

[10] See Iñigo Carrera 2012. It is precisely those more concrete *juridical* expressions of free consciousness – the notion of legal personality – that recent contributions within Marxism have developed (Fine 2002; Reuten and Williams 1989; Miéville 2005), in general on the basis of a critical appropriation of the pioneering work of Pashukanis (1983). However, my point is that the determination of free consciousness as the concrete form of the alienated consciousness already obtains at the more abstract level of the materiality of the organisation of the development of productive subjectivity. It is to this more abstract determination that I have been referring. As Marx puts it in the *Grundrisse*, the juridical concrete forms taken by the free productive subjectivity of the private working individual are just 'this basis to a higher power': 'Therefore, when the economic form, exchange, posits the all-sided equality of its subjects, then the content, the individual as well as the objective material which drives towards the exchange, is *freedom*. Equality and freedom are thus not only respected in exchange based on exchange values but, also, the exchange of exchange values is the productive, real basis of all *equality* and *freedom*. As pure ideas they are merely the idealized expressions of this basis; as developed in juridical, political, social relations, they are merely this basis to a higher power' (Marx 1993, p. 245).

> of his natural existence is already implied; that he is therefore entirely determined by society; that this further presupposes a division of labour etc., in which the individual is already posited in relations other than that of mere *exchanger*, etc. That therefore this presupposition by no means arises either out of the individual's will or out of the immediate nature of the individual, but that it is, rather, *historical*, and posits the individual as already *determined* by society. It is forgotten, on the other side, that these higher forms, in which exchange, or the relations of production which realize themselves in it, are now posited, do not by any means stand still in this simple form where the highest distinction which occurs is a formal and hence irrelevant one. What is overlooked, finally, is that already the simple forms of exchange value and of money latently contain the opposition between labour and capital, etc.[11]

In this passage, Marx raises two critical points. First, against those who want to preserve the forms of freedom and equality which emerge out of the simple circulation of commodities without its transformation into a process of capitalist exploitation, he states that simple circulation is just the abstract form in which capital's valorisation process – the exploitation of labour – appears. This is the part of Marx's critique of modern freedom and equality that is generally – and correctly – emphasised within Marxism, usually in debates over the derivation of the state form.[12] But note that Marx develops another aspect of his critique, which is precisely the one I have been stressing. Namely, that even at the level of abstraction of the commodity form, the freedom of private individuals is revealed as the way in which they act as personifications of the social determinations of their commodities. Their free consciousness is the concrete form of subjectivity of their 'existence only as producers of exchange value'.

Leaving exegetical questions aside, my discussion should have made clear that even if not explicitly addressed by Marx, the whole section on commodity fetishism latently contains the exposition of the determinations of free productive consciousness as the form of an essentially alienated consciousness. At any rate, the important point is not whether Marx said it or not, but what are the implications of this discovery of the inner connection between freedom and alienation in the capitalist mode of production for the determination of science as practical criticism and, on the other hand, what are the consequences of overlooking it? In the following section, I move to the discussion of these further fundamental issues in order to show, once again, that only on the basis of the dialectical method can these questions be adequately dealt with.

Why Does Method Make a Difference? The Implications of Marx's Investigation of the Commodity Form for the Determinations of Revolutionary Subjectivity

The discussion in the previous section permits me to draw a first provisional conclusion about the *differentia specifica* of Marx's *critique* of political economy, as opposed to political economy or sociology (no matter how radical or 'Marxist' their political stance). Through the ideal reproduction of the determinations of capital, Marx discovers its historical specificity in the private form taken by social labour, this being the general social relation of production regulating the reproduction of human life and hence the development of human productive subjectivity. As an expression of this historical form of social being, the consciousness of the private and independent individual becomes concretely determined as alienated. This alienated consciousness acquires two concrete modes of existence: objectively, it takes the value form of the product of labour thereby determined as a commodity; subjectively, it is realised through the apparently free consciousness of the modern individual. The most general defining characteristic of Marx's scientific enterprise as a *critique of political economy* consists precisely in the discovery of this *twofold* determination of social existence (hence social consciousness) in capitalist society. As the essential *content* of revolutionary knowledge of capitalist social forms, those discoveries can only be the result of its *dialectical form*. In order to substantiate this point further, let us see the consequences of the attempt ideally to apprehend the determinations discussed above through the lenses of *representational thought*, i.e. through *logic* (whether formal or dialectical), an issue which, I think, has also been insightfully and systematically explored by Iñigo Carrera and beyond the insight Marx left us explicitly in *Capital*.[13]

In the case of formal logic, the question is very straightforward. Since it conceives of real forms as isolated immediate affirmations, freedom and alienation repel each other by definition. From this point of view, freedom is freedom, and alienation is alienation, there being no way that one could be the mode of existence of the other. If, as generally happens, it stops short at the more immediate appearances of bourgeois society, it falls prey to the illusion that the human individual is free by nature and that the 'objective context' of capitalist social relations allows that freedom to express the plenitude of its potentialities. This has been the simplest element defining the apologetic character of *bourgeois* social science. This is perfectly compatible with the postulation of this or that external limitation to the affirmation of freedom engendered by the autonomised regulation of capitalist social relations. In this case, adequate social reform by the state is conceived of as being capable of removing those constraints, thereby leading to a kind of capitalism with a 'human face'.[14] Still, formal logic has even made its incursions within Marxism. Rational Choice or Analytic Marxism is a case in point.[15] In this more radical version, this formal-logical representation could even find the constraints to the affirmation of freedom in whole 'institutions' which they see as defining the capitalist mode of production itself. For instance, this would be the case of capitalist private property, which is seen as limiting freedom by leading to an unjust distribution of social wealth, resources and/or capabilities. Hence, defenders of 'market socialism' see the transcendence of capitalism as entailing the preservation of the freedom and independence inherent in the commodity form, which they take as given as the natural form of productive subjectivity of human beings, but without the inequality springing from private property in the means of production. In other words, they put forward a political programme which postulates the oxymoron of wanting to preserve the commodity as the general social relation without its necessary development into capital. Here formal logic provides these Marxists with another service: the respective existences of the commodity form and the capital form are just immediate affirmations, so we can have one without having the other.

---

[13] Iñigo Carrera 2007, pp. 67ff.; and 2008, pp. 252–6.

This inability to grasp the real relation between freedom and alienation in capitalist society manifests itself in a more subtle way in the case of *dialectical logic*.[16] The latter, I think, has been the way in which Marxism has been attempting to grasp said relation between free consciousness and alienated consciousness, which can be seen as such an application of a dialectical logic. In this case, the issue is all the more relevant since it directly pertains to the central theoretico-practical question I have been tracing in this book, namely, the determinations of revolutionary subjectivity. In a nutshell, the question at stake is the following: if the general social relation regulating human life in the capitalist mode of production takes concrete form in a reified consciousness, how is the overcoming of alienation and consequent affirmation of human freedom possible? The question turns out to be posed in terms of the relation between the form of consciousness bound to reproduce its alienation and the one embodying the potentiality of its transcendence, i.e. revolutionary subjectivity. And here is where – more or less explicitly – dialectical logic comes into play. Sticking to the apparent external relation between free subjectivity and alienated subjectivity in the capitalist mode of production, the consciousness of the subject of revolutionary transformation – the working class – is logically represented as the antagonistic unity of those opposing determinations.[17] What is more, the relation is not only grasped in an external fashion, but also becomes actually inverted. Hence, also falling prey to the appearance of 'free creative subjectivity' as the natural attribute of human beings, the dialectical-logical representation conceives of the latter as the essential pole of that relation which is contradicted by the coexistence of the reified pole, in turn seen as constituting the inessential or apparent side of that relation. The difference between the different currents arises by virtue of the precise way in which they conceptualise that unity of opposing yet immediate affirmations.[18] But in all cases, working class consciousness is more or less implicitly represented as the unity of an alienated pole ('false' or 'reified' consciousness) and a free one (the true class consciousness, corresponding to the essential being of the proletariat as the 'universal class'). In turn, each pole is usually assigned to a specific kind of action by workers so that some forms of working-class action are seen as being the affirmation of a false or reified consciousness, whilst others – in particular, revolutionary action – are seen as the affirmation of the workers' essential freedom, i.e. not determined as a concrete form of their alienation in capital.[19] At most, this dialectical-logical representation could go as far as submitting that the antagonistic unity of opposites permeates all capitalist social existence, so that the two poles cut across every manifestation of class struggle (indeed, the singularity of each human subject), there being no privileged form of action which can be said to express the affirmation of a pure non-alienated subjectivity. 'Reform' ('labour as a moment of social reproduction in the form of capital') and 'Revolution' ('as process in and against capital in terms of working class self-determination') are therefore seen as constituting 'extreme poles of a dialectical continuum that social practice represents'.[20]

---

[14] This is, for instance, Keynes's utopia in the *General Theory*, which amounts to capitalism without capital (Kicillof 2004).

[15] See Roemer 1986. An excellent critique of Rational Choice Marxism can be found in Bensaïd 2002.

[16] On the distinction between dialectical *method* and dialectical *logic*, see the discussion of Marx's critique of Proudhon in Chapter 3.

---

[17] Iñigo Carrera 2008, p. 254.

[18] Thus, note that this applies both to so-called 'Leninist' and 'spontaneist' conceptions. The difference between them resides in the concrete social subject that appears as the immediate bearer of that freedom: the vanguard (who must guide or enlighten, and hence liberate, workers) or the working class as a whole. But in both cases, the 'substance' of revolutionary subjectivity is the apparently natural freedom of the human being.

[19] See footnote 50 of Chapter 7 for various references to this ontological or transcendental grounding of revolutionary class struggle in diverse currents of Marxism. But take, for instance, Lukács's argument in *History and Class Consciousness*. In that text he stresses that, at least in its immediacy, the standpoint of the proletariat is not different from that of the bourgeoisie; it is a reified consciousness and, hence, cannot go beyond the immedi-

---

ate appearances of capitalist society in order radically to transform it (Lukács 1971, p. 150). However, he later claims that any transformation can only come about 'as the product of the *free* action of the proletariat itself' (Lukács 1971, p. 209, my emphasis). The most paradigmatic expression of the grounding of revolutionary action in a pure 'autonomous creativity' of the subject within Marxism can be found in the Autonomist's 'inversion of class perspective' centred on the concept of working-class 'self-valorisation', which designates the self-determined positive power to constitute new practices outside capitalist social forms (Cleaver 1992, pp. 128ff.; De Angelis 2007, pp. 225ff.). Furthermore, this pure affirmation of the working class as autonomous subject is considered as (onto)logically prior to its 'cooption' or 'repression' by capital, deliberately represented, in line with post-structuralist thinking, as an external and self-constituting 'disciplinary' power (Hardt 1993). Thus, according to De Angelis, the theoretical starting point for the understanding of revolutionary subjectivity must be the self-sustaining *affirmation* of the multiplicity of needs, aspirations, affects and relations of human subjects (De Angelis 2005).

[20] Bonefeld 1992, p. 102. Thus, as evidenced in the quote above from Bonefeld, so-called Open Marxists consider that the moment of 'transcendence' (i.e. revolutionary subjectivity), even if always intertwined with 'integration' (the determination of the wage worker's alienated subjectivity as personification of the reproduction of capital), is the expression of working-class *self-determination*, that is, as an element of subjectivity that is not a mode of existence of (hence determined by) the capital form. Open Marxists are usually at pains to overcome the externality between labour and capital extolled by 'Autonomist Marxists' (see previous footnote), without relapsing into a structural functionalism (e.g. Jessop 1991) that reduces class struggle to a form of the reproduction of capital and denies its capital-transcending potentialities (Bonefeld 1993, pp. 26–8). They do so precisely by emphatically stressing the 'internal or dialectical relation' between labour and capital as one between material content ('the constitutive power of human practice') and its alienated mode of existence ('social reproduction as domination'). However, when it comes to grounding the determination of the class struggle as capital-transcending revolutionary action, this initial premise is left behind. In the very course of their argument, they surreptitiously transform contradiction, from a self-negating mode of existence of a determinate content, into an interpenetration of two antagonistic opposite contents in struggle that cut across the working class itself: the aforementioned 'dialectical continuum' between integration and transcendence ('the presence of labour *in and against* capital'), whose resolution is 'open to the process of struggle itself' (Bonefeld 1992, p. 102).

Moreover, the specifically revolutionary resolution of that struggle is seen as an *unmediated* assertion of the undetermined, residual and pristine human content lurking behind those fetishised social forms. 'Revolution', Gunn and Wilding thus state in a recent sympathetic critical assessment of Holloway's *Crack Capitalism*, 'is an expression and articulation of already-free action' (Gunn and Wilding 2012, p. 178), albeit one which exists in a 'distorted form' *in a pre-revolutionary situation* (Gunn and Wilding 2012, pp. 181–2). In other words, for Gunn and Wilding, mediation only pertains to capital-reproducing 'moments' of subjectivity, but not to the revolutionary 'pole of the continuum', which is seen as an affirmation of the human being's innately free self-determining subjectivity that 'breaks through' its alienated 'integument'. This shows very clearly in the way they conceptualise 'uncontradicted self-determination', in a twofold sense. In the first place, when they claim that in a generally non-revolutionary situation, such an uncontradicted self-determination already makes its appearance within an alienated society, albeit in a 'proleptic or prefigurative' fashion, in and through 'islands of mutual recognition' in the 'cracks and fissures' of a contradictory social world (Gunn and Wilding 2014). Out of the blue, human life is now turned into the unity of two intertwining opposites: an alienated pole for the greater part of social existence and a free one in those 'islands of mutual recognition'. In the second place, it is noteworthy how they construct their concept of freedom on the basis of Hegel's concept of recognition as played out in the Master-Slave dialectic from Chapter IV of his *Phenomenology of Spirit* and further developed historically in Chapter VI, which culminates with the discussion of patterns of recognition in the French Revolution. In other words, they construct the ground of the communist revolution based on a conceptual framework whose actual content is but the emergence and concrete development of the modern, capitalistic 'self-determining' freedom of the commodity owner out of relations of personal dependence, which is ideologically presented by Hegel in an inverted fashion as the movement of an abstract individual self-consciousness deprived of social determinations. As a consequence of all this, their critique of Holloway's occasional appeal to a 'pristine' or 'undistorted' freedom is thus limited to noting that 'such an immediacy that lies outside alienation's realm' cannot be taken '*as starting point*' for the search for the genesis of revolutionary subjectivity within a non-revolutionary situation (Gunn and Wilding 2012, p. 184), yet it does constitute the 'key' to (i.e. the content of) its interstitial emergence and eventual proliferation. Hence, despite their best efforts, Open Marxists end up sneaking an abstractly free subjectivity through the backdoor as the ground for the revolutionary transformation of society. In the end, the difference from the Autonomists comes down to a more sober and cautious *subjective attitude* when assessing 'really-existing' working-class struggles. Against the 'euphoric and triumphalist poetry that prevails in various *Autonomia*-influenced accounts', Gunn and Wilding's Open Marxist perspective 'allows for respect for a reality principle (in Freud's sense)' (2012, p. 182), a 'word of warning' about the 'difficulties' and 'complexities' involved in revolution. But the ground of revolutionary subjectivity in an abstractly free and self-determined subject remains the same. I return to the critical engagement with the Open Marxist approach in the next section, through a discussion of the practical nature of 'defetishising' critique.

Still, I think that despite their differences and distinct degrees of sophistication and depth, a common thread runs through most of those conceptions. And this is the idealist notion that, somehow or another, the revolutionary consciousness embodying the overcoming of alienation derives from some more or less residual element of externality to the alienated general social relation through which human beings reproduce their life in capitalist society. In other words, the source of the power to abolish the capitalist mode of production is to be sought in the (smaller or larger) irreducible element of free, self-determining productive subjectivity, eternally present in human life. It is the immediate affirmation of this abstract freedom that is seen as constituting the substance of the revolutionary abolition of alienated social existence. As Postone rightly points out, the underlying assumption of that train of thought is that 'revolutionary consciousness must be rooted ontologically or transcendentally'.[21]

---

[21] Postone 1996, p. 39. As an illustration of this, see the contributions to the symposium on Postone's 'Time, Labor and Social Domination'. With the exception of Stoetzler (2004) and Neary (2004), most authors explicitly distance themselves from the view that the subsumption of the working class to capital (hence alienation) is total and end up postulating a moment of human subjectivity external to its inverted mode of existence as the transcendental or ontological ground for revolutionary consciousness (see Albritton 2004; Bonefeld 2004; Arthur 2004b; Hudis 2004; McNally 2004). As I have argued above (see footnote 1), Postone himself cannot follow through his initial insight right to its full implications and ends up grounding revolutionary consciousness in a self-activating transformative action that reacts to the contradictions of its 'objective conditions', which are therefore rendered external to the subject (as opposed to immanently carried by subjectivity). On the other hand, even authors like Stoetzler who, as just mentioned, does not 'recoil in horror' in the face of the social constitution of capital as alienated total subject (see also Stoetzler 2012, p. 200, n. 7), ends up grounding capital-transcending action outside capital, in an abstract freedom of the subject. Thus, after critically noting that the notion of an abstract, pure subject keeps being reintroduced through the back door in Holloway's earlier argument in *Change the World without Taking Power* (Stoetzler 2005), in his assessment of Holloway's more recent formulation in *Crack Capitalism*, Stoetzler makes an extremely problematic (yet thought-provoking) distinction between *revolution*-as-the-negation-of-capital (which would be done by *us-as-capital*) and *communism*-as-the-negation-of-capital (which would be done by *us-as-not-capital*) (Stoetzler 2012, p. 192), i.e. in a moment of subjectivity not determined as personification of objectified forms of social mediation. In reality, Soeltzer's approach just resembles Postone's train of thought which, as discussed above, relapses into positing an externality between the objective and subjective conditions for the abolition of capital; the former conditions creating the *possibility* of communism and the latter abstractly self-developing to undertake (or not) its realisation. However, unlike Postone's implicit assumption, he makes *explicit* his reliance on an abstractly free subjectivity as the source of 'communism-as-the-negation-of-capital':

Now, from where does this notion of self-determining free subjectivity, which constitutes for those Marxist currents the content of revolutionary subjectivity, arise? Certainly not from the imagination of the theorist. When looked at more closely, we can realise that it is in fact the concrete form of the alienated consciousness abstracted from its content, transformed into its 'logical' opposite and, from that apparent exteriority, posited as the source of the revolutionary negation of alienated subjectivity. On the other hand, we can now appreciate how this is just the other side of the unilateral reading of Marx's critique of political economy (and especially, the section on commodity fetishism) solely as a genetic development of the forms of objectivity of capitalist society. Because according to this reading, the fetishism of commodities refers only to the social constitution of an apparently self-subsistent objectivity which confronts individuals as an alien and hostile power that dominates them. In this way, it overlooks the concrete form of free consciousness that is the necessary other side of the constitution of that alienated form of social objectivity.[22] Emancipation is then posed in terms of riddance of the external coercion imposed by those modes of social objectivity upon its self-

---

'*No less, no more*: by way of constituting capital, we also constitute its intrinsic, in-built, inevitable self-negation, but not, in and of itself, communism. Not communism, but only the possibility of communism follows from the inherent contradictions of the capital relation. Although capital's self-negating dynamic produces the elements and conditions of communism, communism is more than just the self-negation of capital. Communism emerges from capitalism only as a potentiality; it is born out of freedom, if it is born at all, not out of necessity. Freedom is what communism essentially is. In other words, the abolition of capitalism will create a chance which humanity has the freedom to spoil or to use. Only because we can spoil it we can also make communism: if it were a guaranteed outcome, it would be freedom arrived at by ways of unfreedom; guaranteed, necessary freedom, though, is implausible' (Stoetzler 2012, p. 193).

[22] Some authors do develop and subject to criticism the notion of bourgeois individuality. But the latter is reduced to *individualism*, that is, to the *atomistic* affirmation of that abstractly free subjectivity. Hence, the collective, solidaristic affirmation of that very same subjectivity in the form of class struggle is seen as the absolute opposite of alienated subjectivity (or, at least, as embodying the immediate potentiality to 'self-develop' into such an absolute negation of bourgeois individuality). See, for instance, Shortall's derivation of a 'counter-dialectic of class struggle' – i.e. 'the potential class subjectivity of the working class' – that 'comes to delimit the functioning of the dialectic of capital', and whose foundation resides in the presupposition of the worker 'as both a free subject and as *non-capital*' (Shortall 1994, pp. 128–9, original emphasis). By contrast, I will show in the next chapter that the solidaristic collective affirmation of that abstractly free subjectivity is but a more concrete realisation of the very same alienated content, hence, of the reproduction of capital.

determination by that apparently free consciousness. In other words, that one-sided reading aspires to get rid of the commodity, money, capital and the state *precisely on the basis* of the concrete form of the alienated consciousness which is the necessary complement of the existence of those forms of objectivity.

As stated above, the *critique* of political economy is such not only for grasping in thought the inner determinations of the value form of the product of labour as an alienated social form, but also for discovering free consciousness determined as the concrete form of alienated consciousness in the capitalist mode of production. By ignoring this second 'leg' of the critique of political economy, Marxism deprives the latter of its revolutionary character and condemns it to remain just another concrete form of the reproduction of alienated human activity. Thus, it thereby transforms the critique of political economy from the revolutionary reproduction of the concrete by means of thought into another logical representation.

Fetishism and Critique in Contemporary Marxian Theory: A Methodological Assessment of Some Recent Contributions

Another methodological issue implicit in the above discussion is the precise nature of the method of critique involved in Marx's account of commodity fetishism. Associated with the aforementioned one-sided reading of commodity fetishism as an account of the genesis of the most general forms of objectivity of capitalist society is what one could term a Feuerbachian understanding of Marx's mature method of critique, i.e. a kind of transformative criticism. Even in its most sophisticated versions, which one could locate in some of the contributions to the so-called *Neue Marx-Lektüre* in Germany,[23] and its Anglophone, more 'political' reception and appropriation by Open Marxist scholars,[24] this critique boils down to demystifying commodity fetishism by tracing the human origins of that alien objectivity. In this sense, there appears to be no difference between this method of critique and the one in the *Paris Manuscripts*. The only difference would be that in *Capital* Marx not only reduces alienated social forms to their human content, but also answers (more fully) the question of why that content takes that fetishistic form. But the thrust of the critique is seen to consist just in uncovering the practical activity of human beings as the social foundation of value.

---

[23] Backhaus 1980, 1992 and 2005; Reichelt 1982, 1995, 2005 and 2007; Heinrich 2009; Fineschi 2009.

[24] Bonefeld 1998, 2001 and 2014. For a concise historical and intellectual contextualisation of the *Neue Marx-Lektüre* in English, see Endnotes 2010.

But if the point is to change the world, then the subsequent problem is how to turn this insight into *practical criticism*, that is, how to convert it into emancipating conscious practice. And here lies the crux of the matter. Because for these readings, that connection seems to be as follows: the recognition of relations between human beings behind relations between things constitutes the foundation of radical transformative action. Since the content of the value form is our conscious practice, i.e. the 'determining power of social labour', then it follows that we must have the power of giving our practice another social form and getting rid of the value form. In other words, for such Marxists the transformative powers of our action are located not in commodity-determined practice itself, but in the essential character of an abstract material content deprived of social determinations which is 'logically' prior to its perverted social form as value-producing, albeit only appearing and existing immanently in and through it. For those readings, this mere discovery of the human content of 'economic categories' exhausts the thinking needed consciously to organise the practical critique of capitalism.[25] Let us examine this matter more closely through a discussion of some of these contributions.

Perhaps a good place to start is the work of Hans-Georg Backhaus, who explicitly traces the Feuerbachian lineage of Marx's method of critique. According to Backhaus, from an initial application 'in his critique of the metaphysical theory of the state', Marx expanded the scope of this method to economic objects as material forms of self-estrangement, commensurable to its metaphysical and theological forms.[26] This 'critical genetic method' is said to have two main aspects – the critical and the anthropological. The former does not simply consist in describing and denouncing the existing contradictions between dogmas and institutions, but aims fundamentally at explicating the inner genesis or necessity of those contradictions.[27] In turn, the anthropological aspect of the method involves an *ad hominem* reduction, the demonstration of the human basis of the economic object as a material form of self-estrangement, which is thus rendered in its totality as an object of critique.[28] The critique of economic categories thus entails the transcendence of the economic standpoint.[29]

---

[25] Holloway 1995 and 2002b; Bonefeld 1995, 2010a and 2012.

[26] Backhaus 2005, pp. 18–19.

[27] Backhaus 2005, p. 19.

[28] Ibid.

[29] Backhaus 2005, p. 23.

In Backhaus's reading, this 'application' of the 'critical genetic method' to the discipline of economics is employed by Marx not only in his early writings (an indisputable fact which I have already discussed in the first part of this book), but also in his mature critique of political economy.[30] The main thrust of the critique remains the same: whilst economics

> accept[s] economic forms and categories without thought, that is in an unreflective manner ... Marx, in contrast, seeks to 'derive' these forms and categories as inverted forms of social relations.[31]

The 'dialectical method of exposition' is thus essentially seen as the genetic development of those alienated forms of *objectivity* out of human sensuous practice.[32] The general method of critique does not change in this reading, only its terminology.[33] In the words of Backhaus himself:

> In variation of this thought process, Marx argues in the mature *Critique* of 1859 that what the economists 'have just ponderously described as a thing reappears as a social relation and, a moment later, having been defined as a social relation, teases them once more as a thing' (Marx 1971, p. 35). If one replaces 'social relation' by 'appearance of humanness' and thing qua 'value thing' by the thing in 'difference from humanness' that, as a transcendental thing, is transposed in a sphere 'outside of Man', then the continuity of the fundamental character of Marx's critique of economics from the early writing to *Capital* becomes sufficiently clear.[34]

Now, lest my argument be misread, my claim is not that these contributions from the *Neue Lektüre* see no methodological change whatsoever between Marx's early critique of economics and his mature version. My point is that they do not posit any change insofar as the nature of *critique* is concerned: the *reductio ad hominem* is considered to be the continuing ground for revolutionary praxis.[35] Yet, this novel reading does develop two additional methodological elements which are relevant for the purpose of the present discussion.

---

[30] Backhaus 2005, pp. 21 ff.

[31] Backhaus 2005, p. 21.

[32] Backhaus 2005, p. 22.

[33] Backhaus 2005, p. 25.

[34] Ibid.

[35] Reichelt 2005, p. 38.

In the first place, these authors argue that in Marx's mature critique, the genetic aspect of his method is not simply predicated on Feuerbach. Insofar as the 'inverted world of capital' (as self-valorising value) resembles Hegel's second supersensible world, 'which in its reality … contains within itself … both the sensuous and the first supersensible world',[36] Marx's mature critique also drew on Hegel's *Logic* for the 'dialectical development of categories'.[37] In other words, Hegel's dialectical method served Marx for the *synthetic* exposition of the necessary sequence of form determinations understood as 'objective forms of thought'.[38]

Secondly, taking cue from Adorno's concept of society as the 'unity of subject and object',[39] which involves 'an ongoing process of inversion of subjectivity and objectivity, and vice versa',[40] both Backhaus and Reichelt posit the alienated determination of human beings as 'personifications of economic categories' or 'character masks', as a central element of Marx's dialectical method in *Capital*.[41] Abstractly considered, this insight could be a promising programmatic starting point for an attempt at a critical investigation of the determinations of revolutionary subjectivity. Unfortunately, this is not a path that these German scholars followed. Their discussion tends to remain at a very high level of abstraction, dealing with the simpler form determinations of capital. As Endnotes write, 'class plays little role in the writings of Backhaus and Reichelt and they treat the question of revolution as outside their field of academic expertise'.[42] Nonetheless, it is possible to examine the practical implications of this approach by turning to the work of Werner Bonefeld who, as stated above, has not only introduced it into Anglophone Marxism, but also developed it further along resolutely political lines, i.e. by putting the revolutionary class struggle at the centre of his investigation.[43]

[37] Reichelt 2005, p. 43.

[38] Reichelt 2005, p. 57.

[39] Backhaus 1992, p. 56.

[40] Backhaus 1992, p. 60.

[41] Ibid; Reichelt 1982, p. 168.

[42] Endnotes 2010, p. 99. It goes without saying that the treatment of the question of revolution as 'outside their field of expertise' by scholars whose research programme revolves around the Marxian notion of *critique* seems quite odd, to say the least. The real reason seems to reside at a deeper level and is actually political. As Endnotes further remark: 'Most accounts of the *Neue Marx-Lektüre* understand as one of its main characteristics to be a rejection of Marx's attribution of an historical mission to the proletariat and a sensibility of scepticism towards the class struggle has been prevalent on the German Left' (2010, p. 98). Moreover, although seldom discussed explicitly by these scholars, there are certain passages in their work which give the impression that they would tend to locate the source of revolutionary subjectivity in a moment of human individuality which transcends its alienated existence as 'character mask': 'Marx presents the humans themselves only insofar as they have intercourse with one another as character masks. Insofar as they come into

A recent article by Bonefeld on Adorno and social praxis is a fertile ground to discuss this issue. The starting point of Bonefeld's discussion is the recognition that in capitalism the 'subject's objectification exists in an inverted form, in which the thing subjectifies itself in the person, and the person objectifies him- or herself in the thing'.[44] In other words, Bonefeld takes up the Adornian insight, which originally triggered the *Neue Marx-Lektüre*,[45] that in this society, individuals become determined as 'character masks' or 'agents of value': their social activity becomes the activity of 'personifications of economic categories'.[46] In more overtly Adornian terms, Bonefeld speaks of this phenomenon as involving a specific 'objective conceptuality', which 'holds sway in reality (*Sache*) itself'.[47] However, unlike Backhaus and Reichelt, Bonefeld explicitly poses the question of the implication of this form determination of human individuality for emancipatory praxis, i.e. for revolutionary class struggle:

> The critique of political economy is not satisfied with perpetuating the labourer. Its reasoning is subversive of all relations of human indignity. Subversion is not the business of alternative elites that seek revolution as mere conformist rebellion – a revolution for the perpetuation of wage slavery. Their business is to lead labour, not its self-emancipation. Subversion aims at general human emancipation.[48]

---

relation with one another as individuals, they are not the object of the theory. Insofar as they act as individuals, they withdraw from the building of theory in this specific sense; there they anticipate something which still has to be constructed' (Reichelt 1982, p. 168). If my reading is correct, rather than simply residing 'outside their field of expertise', for these scholars revolutionary subjectivity would lie outside the scope of the dialectical presentation of 'economic categories'.

[43] Endnotes 2010, p. 98. For an earlier assessment of the relation between value-form theory, systematic dialectics and revolutionary politics, see also the discussion provided by Eldred 1981.

[47] Bonefeld 2012, pp. 125–6.

[48] Bonefeld 2010a, pp. 62–3.

The interesting thing about Bonefeld's answer to this question is that, at least in principle, he explicitly rejects those attempts at grounding 'resistance' against reification in an 'asserted subject conceived in contradistinction to society', and whose transhistorical basis would be the worker's 'humanity and soul' (Lukács), 'the inner transcendence of matter' (Bloch), a 'materialist instinct' (Negt and Kluge), or biopower (Hardt and Negri).[49] In other words, Bonefeld is at pains not to relapse into any exteriority to the perverted forms of existence of the social individual as the ground for the revolutionary subject:

> And Adorno? He would have none of this. The idea that there is a world out there that has not yet been colonized by the logic of things is nonsensical. Instead of a concept of society, these differentiations of society into system and soul/transcendent matter/materialist instinct/bio-power separate what belongs together.[50]

Bonefeld elaborates further on this through a 'philosophical' discussion of Hegel's conception of the relation between essence and appearance.[51] Essence, he argues following Hegel, has to appear (it cannot choose not to do so). Moreover, this appearance is its (only) mode of existence. This means that there is no exteriority to essence's actual manifestation, however perverted the latter might be: 'its appearance is thus at the same time its disappearance'.[52] Translated into social theory, this philosophical argument means that human sensuous practice (essence) does exist as personification of economic categories (appearance), and that this inversion is no mere subjective illusion, but is all too real. Now, whilst this certainly allows Bonefeld formally to avoid relapsing into an externality between human subject and society, it begs the question as to how to avoid the political dead-end to which Adorno pessimistically succumbed. In other words, the question arises as to how to avoid the conclusion that 'there could be no such thing as emancipatory praxis because the reified world of bourgeois society would only allow reified activity'.[53]

---

[49] Bonefeld 2012, p. 131. As Charnock and Ribera-Fumaz (2011, p. 617) note, Henri Lefebvre is also an exemplary proponent of this kind of 'residualist' view of revolutionary class struggle. For a critical discussion of the relationship between Lefebvre's contribution and the Open Marxist tradition, see Charnock 2014.

[50] Bonefeld 2012, p. 131.

[51] Bonefeld 2012, pp. 127–8.

[52] Bonefeld 2012, p. 128.

[53] Bonefeld 2012, p. 124.

And here lies the crux of the matter, because, in my view, Bonefeld can remain true to the project of emancipatory praxis only by backtracking on his declamation to reject any exteriority between 'essence' and 'appearance'. Thus, right after claiming that the former vanishes in the latter, he endorses Adorno's claim in *Negative Dialectics* that 'objects do not go into their concepts without leaving a remainder' since 'the concept does not exhaust the thing conceived'.[54] According to Bonefeld, the critical move consists in 'opening the non-conceptual within the concept'.[55] This non-conceptual content, Bonefeld further argues, 'subsists within its concept but *cannot be reduced to it*'.[56] Crucially, *it is this moment of irreducibility of the content which, in that simplicity and unmediatedness, constitutes the ground of revolutionary subjectivity*. In other words, the latter is seen by Bonefeld as the expression of the direct affirmation of the ('non-conceptual') content. The fact that he does not see this affirmation as a pure positivity but only as negation of 'the negative human condition'[57] makes no difference. The point is that the immediate 'source' of that negativity is located in the (formless) content itself: 'Subversion is able to negate the established order because it is "man" made'.[58] The postulate of immanence between content and form ultimately thereby remains just a formal declaration which is belied as the argument unfolds. In the end, an element of exteriority to alienated social practice creeps back in as the residual 'substance' of revolutionary subjectivity.[59]

---

[54] Adorno 2007, p. 5.

[55] Bonefeld 2012, p. 130.

[56] Bonefeld 2012, p. 130, my emphasis.

[57] Bonefeld 2012, p. 130.

[58] Bonefeld 2010a, p. 66.

[59] In more concrete terms, Bonefeld puts it as follows: 'For example, the conceptuality of the wage-labourer as a personification of variable capital entails what it denies. It denies sensuous practice, and this practice is immanent in the concept wage-labour. Sensuous practice exists within the concept of variable capital in the mode of being denied – sensuous practice cannot be reduced to the concept of variable capital – it subsists within its concept but cannot be reduced to it. Further, for variable capital to function, it requires the ingenuity and spontaneity of human purposeful practice. Yet, this too is denied in its concept' (2012, p. 130). The revolutionary class struggle is seen by Bonefeld as an expression of that sensuous human practice that 'variable capital' denies. In actual fact, his point seems to be that all struggles by workers express something more than their social determination as personifications of 'variable capital', namely, their 'human social autonomy' and 'freedom'. That is why they can always potentially develop, in and of themselves (i.e. not as expressions of any concrete social determination), into communist struggles. See Bonefeld 2010a, pp. 68–72.

Now, I have already discussed at greater length the shortcomings of this kind of approach in the previous section. Here the important point to address is the implication of this conception of revolutionary subjectivity for the *meaning of science as critique*. Briefly put, for Bonefeld, dialectical critique comes down to the demystification of 'economic categories' by revealing their social constitution as perverted modes of existence of human activity, that is, by discovering sensuous practice as the negated content behind those reified forms of social mediation.[60] What follows from this is that, for Bonefeld, the 'subversive' moment of Marx's methodological programme is essentially *analytic*: it consists in the discovery of the content of a determinate form. Drawing on the work of Backhaus commented on above,[61] it is through *reductio ad hominem* that science as critique provides enlightenment on revolutionary practice.

Yet I have shown in earlier chapters that dialectical analysis is actually incapable of offering an *explanation* (hence comprehension) of the *raison d'être* of determinate concrete forms of reality. In moving 'backwards' from concrete form to content, dialectical analysis can at most reveal *what* are the more abstract determinations whose realisation is presupposed and carried by the immediate concrete form under scrutiny. But it cannot account for its 'why' (i.e. its necessity). In this sense, the analytical discovery of the human content of fetishised relations between things can shed little light on the comprehension of revolutionary subjectivity. As we have seen, that was the achievement of the early Marxian critique of political economy, which allowed him to grasp the *simplest* (human) determination behind the content and form of the abolition of the fetishism of capitalist social relations. But the whole point of Marx's subsequent scientific endeavour was precisely to advance in the comprehension of the *further mediations* entailed by the social and material constitution of the revolutionary subject, which could only be the result of their *synthetic* ideal reproduction.

Evidently, this presupposes that one considers that there actually *are* further mediations that need to be unfolded synthetically in order fully to comprehend revolutionary practice. But this is what Bonefeld's approach denies. As I have argued, despite his critique of other perspectives that resort to the immediacy of 'an asserted subject externally counterposed to society', his own endeavour ultimately finds the immanent ground of revolutionary subjectivity in something simple and unmediated, i.e. the abstract materiality of 'sensuous human practice' which 'lives within and through relations between things'. Bonefeld's restriction of the subversive moment of dialectical critique to analysis is therefore perfectly coherent on this score. In his view, when it comes to revolutionary subjectivity, there are actually no *determinations* at stake, there is nothing to be explained. In other words, the revolutionary abolition of capital has no material, social or historical *immanent necessity*.[62] Its only 'necessity' is moral, the practical realisation of the 'communist categorical imperative of human emancipation'.[63] In brief, it is the result of an abstractly free and socially autonomous political action, represented as the absolute opposite of the alienated automatism of the capital form (albeit one that can only exist as 'negativity', i.e. in the struggles 'in and against' capitalist oppression):

---

[60] Bonefeld 2001, pp. 56–9; and 2012, p. 127.

[61] Bonefeld 1998.

> The existence of the labourer as an economic category does therefore not entail reduction of consciousness to economic consciousness. It entails the concept of economy as an experienced concept, and economic consciousness as an experienced consciousness. At the very least, economic consciousness is an unhappy consciousness. It is this consciousness that demands reconciliation: freedom turns concrete in the changing forms of repression as resistance to repression.[64]

It follows that the only thing that actually requires explanation is the social constitution of the fetishised forms of objectivity in which human practice exists in capitalism. In this sense, Bonefeld acknowledges that the critical power of the dialectical method involves not only analysis, but also, fundamentally, synthetic or 'genetic' reproduction. Thus, in an article on the meaning of critique, he approvingly quotes Marx's methodological remark that

---

[62] Bonefeld 2010a, p. 64. Taking at face value the orthodox Marxist *mechanistic* (hence extrinsic) notion of determination of subjectivity for the only available one, Bonefeld can only see in the idea of historical necessity an accommodating and passive attitude towards the alienated laws of motion of capital. It can never be the point of departure for the conscious organisation of its practical abolition: 'The future that will come will not result from some objective laws of historical development but will result from the struggles of today. The orthodox argument about the objective laws of historical development does not reveal abstract historical laws. It reveals accommodation to "objective conditions", and derives socialism from capitalism, not as an alternative but as its supposedly more effective competitor. There is no universal historical law that leads humankind from some imagined historical beginning via capitalism to socialism. Neither is history on the side of the working class. History takes no sides: it can as easily be the history of barbarism as of socialism' (Bonefeld 2010a, pp. 63–4).

[63] Bonefeld 2010a, pp. 66, 77.

[64] Bonefeld 2010a, p. 71.

> It is, in reality, much easier to discover by analysis the earthly kernel of the misty creations of religion than to do the opposite, i.e. to develop from the actual, given relations of life the forms in which these have been apotheosized.[65]

However, this synthetic reproduction is recognised by Bonefeld as the only materialist and scientific method for the genetic development of perverted social forms, i.e. for the social constitution of fetishised *forms of objectivity* out of human relations. As far as forms of *subjectivity* are concerned, they might at most be considered part of the genetic development of forms only insofar as individuals 'act rationally as executors of economic laws over which they have no control',[66] which for this approach is the only aspect under which human beings act as personifications of economic categories. But as for *antagonistic* forms of subjectivity and action, they seem to fall outside the scope of the systematic unfolding of 'economic categories' (except, of course, as instances of abstract negation of the latter's self-movement, i.e. as struggles *against* it). Thus Bonefeld states: 'Does it really make sense to say that workers personify variable capital? Variable capital does not go on strike. Workers do'.[67] And they do so not (only?) as owners of labour power trying to secure the reproduction of their commodity. More importantly, the workers struggle daily against 'the capitalist reduction of human purposes to cash and product'.[68]

In sum, for this kind of approach the synthetic movement of the dialectical exposition concerns the social constitution of 'economic categories' and the continuous process of reproduction of the constitutive premise of their existence at every turn of the conceptual development. Bonefeld locates this premise in the 'logic of separation' of labour from its conditions,[69] i.e. in the *formal subsumption of labour to capital.* But the systematic sequence does not entail any progress in the knowledge of the immanent determinations of revolutionary subjectivity. The significance that Bonefeld attaches to the culminating point of Marx's systematic exposition in Volume 1 of *Capital*, which for him should be better confined to the concept of *primitive accumulation*, is symptomatic in this regard.[70] The chapter on the 'historical tendency of capitalist accumulation' only matters insofar as 'it also continues the process of expropriation in its own terms, as capital centralization'.[71] As for the revolutionary expropriation of the expropriators and the bursting asunder of the capitalist integument that Marx posits as the necessary outcome of the alienated socialisation of private labour, Bonefeld considers that they should be left aside as 'desperately triumphal remarks'.[72] This should come as no surprise. As I have shown, according to his approach, revolutionary subjectivity is quite simply self-grounded in an abstract inner negativity, which is expressed in every manifestation of resistance to oppression. However, I have also shown that this idea is deeply problematic: it entails the naturalisation of the apparently free consciousness of the commodity producer and hence the practical impotence to abolish the fetishism of commodities.[73] The connection between science as critique and commodity fetishism thus requires an alternative formulation. To this discussion I will now turn.

[66] Bonefeld 2012, p. 128.

[67] Bonefeld 2010a, p. 68.

[68] Bonefeld 2012, p. 72. As we shall see in the next chapter, strictly speaking, workers do not go on strike as 'variable capital', but as owners of the commodity labour power. Be that as it may, the point is that they do it in full accordance with their alienated social being as 'executors of economic laws that they cannot control' and not in 'defiance' of them.

[69] Bonefeld 2011b, p. 395.

Commodity Fetishism and Science as Practical Criticism

According to the approach developed in this book, the question must be posed differently. As already argued in the first part, the starting point of a truly dialectical critique of political economy must be our own conscious practice in its singularity. Science as practical criticism is such for being the conscious organisation of transformative action. Thus, the question under investigation when engaged in dialectical research relates to the social determinations, i.e. the necessity, of our action.[74] Only on that basis can we come to know what concrete form our action should take in order to achieve the willed transformation of the world. As Lukács puts it in *History and Class Consciousness*, the question at stake is the establishment of the 'genuine and necessary bond between consciousness and action'.[75]

---

[70] It is also symptomatic that in his otherwise rigorous, stylised reconstruction of the systematic sequence of Marx's exposition in *Capital*, Volume 1, the concrete forms of production of relative surplus value are absent (Bonefeld 2011b, pp. 392–5). As we shall see later on, it is precisely in those chapters on the *real subsumption of labour to capital* that Marx unfolds (albeit incompletely) the determinations of revolutionary subjectivity.

[71] Bonefeld 2011b, p. 394.

[72] Bonefeld 2011b, p. 395.

[73] Iñigo Carrera 2007.

[74] Iñigo Carrera 1992, p. 1.

My own reconstruction of Marx's dialectical investigation of the determinations of the commodity form (commodity fetishism included) thus leads to a different conclusion regarding the social determinations of revolutionary action. True enough, in this process of cognition we become aware of the human content of the objective social powers borne by the commodity. However, what follows from this insight is not that we therefore immediately carry the power to negate the commodity form of our general social relation. Rather, it follows that whatever power we might have to radically transform the world must be a concrete form of the commodity itself. Yet, far from revealing the existence of that transformative power, the abstract determinations of social existence contained in the commodity form show no potentiality other than the reproduction of that alienated social form. So much so that the free association of individuals (the *determinate* negation of capitalism) appears in Chapter 1 (incidentally, precisely in the section on fetishism) as the *abstract* opposite of value-producing labour and hence, as the *extrinsic* product of the *imagination* of the subject engaged in that process of cognition. Thus, Marx starts that passage referring to communism by saying 'let us finally *imagine* …'[76]

Thus, the defetishising critique of revolutionary science does not simply consist in discovering the constituting power of a generic human practice as the negated content of capitalist alienated forms, which would constitute the ground for our revolutionary transformation of the world. Rather, it involves the production of the self-awareness that the reproduction of human life in all of its moments, *including our transformative action*, takes an alienated form in capitalism. The immediate result of the demystifying critique of the fetishism of commodities is to become conscious of our own alienated existence, i.e. of our determination as personifications or 'character masks'. This *is* our general social being and there is no exteriority to it. This means that fetishism *is total* which, in turn, means the social powers of our transformative action are effectively borne by the product of labour and we cannot but personify them.

---

[75] Lukács 1971, p. 2. As I have argued elsewhere (Starosta 2003), although Lukács correctly posed the problem of dialectical knowledge as practical criticism, he eventually *failed* in establishing that link between consciousness and action. This failure lies behind his relapse into the Leninst separation between scientific organisation and execution proper in the political action of the working class (Starosta 2003, pp. 57–8).

[76] Marx 1976g, p. 171, my emphasis.

This obviously bears on the question discussed earlier on the relationship between alienation and freedom. Specifically, this means that upon consciously discovering the social basis of the value form, we do not *cease* to be determined as its personifications and become able to affirm an abstractly free self-determining action. What this discovery changes is, as Iñigo Carrera puts it, that our social determination as personification of the commodity no longer operates behind our backs.[77] In this way, we do affirm our freedom. However, we do so not because we realise that 'in reality' we are free beings by nature and could thereby choose to 'stop making capitalism' if we tried hard enough, i.e. if we *turned our backs* on our social being.[78] Instead, through the critical investigation of the value form we affirm our freedom because we come *consciously to cognise* our own determination as alienated social subjects.[79] Armed with that objective knowledge of the alienated nature of our subjectivity, we could *consciously act upon* those alienated determinations in order to transform them in the direction of their revolutionary transcendence. Still, this would only be possible if those determinations actually carried the objective potentiality for their self-abolition, which is something that the simple commodity form of social relations does not show. This does not mean that commodity fetishism cannot be abolished. It only signals the need to move forward in the dialectical investigation of the more concrete social determinations of its revolutionary abolition.

Perhaps a good way to clarify this argument is by examining a methodological external remark that Marx introduces when discussing the function of money as means of payment in the 1859 *Contribution to the Critique of Political Economy*. It is worth quoting that profoundly rich text at length:

> But the metamorphosis of commodities, in the course of which the various distinct forms of money are evolved, transforms the commodity-owners as well, and alters the social role they play in relation to one another. In the course of the metamorphosis of commodities the keeper of commodities changes his skin as often as the commodity undergoes a change or as money appears in a new form. Commodity-owners thus faced each other originally simply as commodity-owners; then one of them became a seller, the other a buyer; then each became alternately buyer and seller; then they became hoarders and finally rich men. Com-

---

[77] Iñigo Carrera 2007, p. 204.

[78] Cf. Holloway 2010.

[79] Iñigo Carrera 2007, p. 204.

> modity-owners emerging from the process of circulation are accordingly different from those entering the process. The different forms which money assumes in the process of circulation are in fact only crystallisations of the transformation of commodities, a transformation which is in its turn only the objective expression of the changing social relations in which commodity-owners conduct their exchange. New relations of intercourse arise in the process of circulation, and commodity-owners, who represent these changed relations, acquire new economic characteristics.[80]

This passage could be read as a kind of *dynamic* development of the alienated determination of human productive individuality, whose simplest expression Marx presented through the discussion of the fetishism of commodities. As we have seen, in the latter text Marx unfolds the way in which the productive consciousness of the private individual unconsciously posits its own immanent determinations in the external form of the value-objectivity. Subsequently, he shows how the very subjectivity of the commodity producer becomes determined as the personification of those objectified forms of social mediation it had unconsciously engendered. What we have here is a statement of the transformative dynamics structuring the constitution of novel forms of subjectivity as an expression of the further concretisation of the 'law of value' beyond its simplest form. It is, as it were, the 'law of private subjectivity' that regulates the development of further concrete forms in which human beings act as 'personifications of economic categories'.

Certainly, those more complex forms in which the movement of value attains unity remain 'only the objective expression of the changing social relations in which commodity owners conduct their exchange', i.e. their *simplest* (social) content remains the general productive relation between human beings. However, the real inversion of those social relations as attributes of things means that human beings cannot consciously control the self-transformation of their subjectivity (at least not with the determinations unfolded so far). This transformation thereby occurs 'behind their back' as a result of the self-transformation of the alienated forms of objectivity through which their social metabolic process takes place. As those objectified forms self-develop and change, commodity owners 'who represent these changed relations, acquire new economic characteristics', i.e. they progressively emerge from the circulation process wearing different 'character masks' from those with which they entered.

---

[80] Marx 1987a, p. 371.

In the passage above, Marx specifies the forms of subjectivity that have emerged up to that particular stage of his presentation. More concretely, he mentions the figure of simple commodity owner, buyer and seller, hoarder and rich man. However, the implication of this discussion is that commodity owners shall undergo further 'changes of skin'. Thus, a few pages later he develops the figure of debtor and creditor,[81] noting also how the corresponding general ideological forms change as well. From religion as the ideological form corresponding to the hoarder, we now move to jurisprudence as the one corresponding to the subjective form of creditor.[82] Furthermore, 'as money develops into world money, so the commodity owner becomes a cosmopolitan', the general ideological form of which is that of 'cosmopolitanism, a cult of practical reason, in opposition to traditional religious, national and other prejudices which impede the metabolic process of mankind'.[83]

The fundamental point of this discussion is that those passages from the 1859 *Contribution* bring out very nicely a claim that I had made earlier about the object of Marx's 'systematic dialectic': it includes both the forms of *objectivity and subjectivity* of capitalist society. But additionally, they implicitly contain important methodological insights into the way in which the genesis of different forms of subjectivity should be materialistically investigated, namely, as necessary mediations of the autonomised self-movement of forms of objectivity. This, I think, is the only method which allows us *immanently* to ground forms of consciousness and will *within* the movement of present-day social relations. Crucially, my central claim is that if we want to stay true to this materialistic approach, this method should not only 'apply' to 'value-reproducing' forms of subjectivity and action, *but must also include revolutionary subjectivity as well.* In other words, the form of 'revolutionary political subject' (more specifically, of our own subjectivity as an individual organ of such a collective class subject) must be immanently unfolded as a much more developed mode of existence taken by the original commodity owner with which the dialectical exposition started.[84]

---

[81] Marx 1987a, p. 373.

[82] Ibid.

[83] Marx 1987a, p. 384.

[84] As we shall see in the following chapters, those transformations of commodity owners do not simply derive from the 'new economic characteristics' with which they 'emerge from the process of circulation' as it develops novel determinations. Instead, they derive from the changes they experience as they enter into, and emerge from, a capitalistic *process of production* that will develop revolutionary transformations as well.

To put it in more general terms, the immanent ground of revolutionary subjectivity is not simple and unmediated. Instead, it is a 'unity of many determinations', which therefore means that its scientific comprehension can only be the result of a complex dialectical investigation involving *both* the analytic movement from the concrete to the abstract, and the synthetic, mediated return to the concrete starting point, i.e. revolutionary transformative action. Dialectical research must therefore analytically apprehend all relevant social forms and synthetically reproduce the 'inner connections' leading to the constitution of the political action of wage labourers as the form taken by the revolutionary transformation of the historical mode of existence of the human life process.

Now, if the reproduction of the concrete in thought shows that the determinations immanent in the commodity form do not carry, in their simplicity, the necessity of transcending value-production, the search for the latter must move forward unfolding the subsequent concrete forms in which the former develop. Our process of cognition still needs to go through more mediations in order to become fully aware of the necessity of our action in the totality of its determinations, i.e. beyond any appearance presented by it. In order to develop the plenitude of its potentiality, this conscious development must reach a concrete form of our alienated social being which embodies a determinate potentiality whose realisation: (a) entails the abolition of alienated labour itself; and (b) has our transformative action as its necessary concrete form. In sum, revolutionary action must personify a concrete determination of value-producing human practice; a determination, however, whose realisation precisely consists in the abolition of value production itself.

Thus, the ideal reproduction of the commodity form is thereby but the *first step* in the broader process of dialectical cognition through which the subject of revolutionary transformation discovers the alienated character of her/his social being and, consequently, of her/his consciousness and will (including its transformative will). However, we shall see that when developed in its totality, this process also produces the awareness of the historical powers developed in this alienated form and, consequently, of the revolutionary action that, as personification of 'economic categories', the emancipatory subject needs to undertake.[85] This is not the awareness of the *external circumstances* or *objective conditions* of a self-determining action.[86] It is the awareness of the *inner determ-*

---

[85] Iñigo Carrera 2008.

[86] Note that Marx himself occasionally relapsed into this representational language of external relations and spoke of conditions and circumstances for human action. An example

inations of our alienated transformative action. Thus, dialectical social science does not look outside our action in order to comprehend the 'objective' circumstances that 'constrain' its affirmation, but rather, in penetrating its immediate appearances, goes right 'inside' it. In this way, the field of human practice is never abandoned. Only by virtue of its dialectical form does the critique of political economy become determined as the fully conscious organisation of human practice in the capitalist mode of production and, hence, as the revolutionary science of the working class.[87]

Thus far, however, this critical reading of Marx's *Capital* has shown no sign of providing us with the consciousness of the concrete determinations of our radical transformative action. In fact, all references to the working class as the revolutionary subject were, strictly speaking, completely extrinsic to the determinations we had before us. Therefore, in the next chapter, I jump ahead in Marx's dialectical presentation right into the heart of the determinations of social existence taking the form of the class struggle, in order to see the extent to which they shed light on the necessity of revolutionary action.

---

of this is the oft-quoted opening lines from *The Eighteenth Brumaire of Louis Bonaparte*: 'Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances directly encountered, given and transmitted from the past' (Marx 1979, p. 103). Contrary to most Marxists who tend to celebrate this passage, I think that it is actually quite unfortunate.

[87] Iñigo Carrera 2007.

CHAPTER 7

Capital Accumulation and Class Struggle: On the Content and Form of Social Reproduction in Its Alienated Form

Introduction

In the previous chapters, I have critically reconstructed Marx's presentation of the determinations of the commodity form and shown the fundamental importance of his dialectical method for a proper understanding of those first steps in the critique of political economy. I have also discussed the implications of such an understanding for the translation of those initial insights into the conscious organisation of the practical abolition of the alienation inherent in the commodity form of social relations. Thus, I concluded that although those first steps already revealed to us the alienated nature of our social existence (hence of our consciousness), they provided no answer to the question about all the social determinations behind our radical transformative action, i.e. about revolutionary subjectivity. The very idea of a revolutionary subject, or even of social life taking the form of a political action, was completely extrinsic to the determinations we had before us. The reproduction of the concrete by means of thought thereby still needs to advance towards more concrete determinations of the real in order to account for the necessity of the practical abolition of alienated social life.

The main aim of this chapter is, therefore, to move forward in the critical reconstruction of Marx's critique of political economy up to the point at which, for the first time in his presentation, he shows capitalist social existence as taking concrete form in an antagonistic political relation between classes. In other words, we shall discuss Marx's presentation of the specifically capitalist determinations of the class struggle. Again, the discussion will be carried out in a methodologically minded fashion, so as to highlight the intrinsic connection between the specific form of Marx's scientific argument and its revolutionary content as practical criticism. I argue that, for Marx, the class struggle is a necessary concrete form in which the accumulation of capital realises its determinations. More concretely, the class struggle is the most general *direct* social relation between *collective personifications of commodities* through which the *indirect* relations of capitalist production assert themselves.[1] This

---

[1] Iñigo Carrera 2008, p. 15.

© KONINKLIJKE BRILL NV, LEIDEN, 2016 | DOI: 10.1163/9789004306608_009

real relation is not grounded in the abstract general principles of structuralist methodology.[2] Rather, it is the necessary expression of the development of the historically specific alienation inherent in the commodity form into its more concrete social form of capital. In other words, that real relation expresses the fact that, as an expression of an alienated social existence, *the total social capital becomes determined as the concrete subject of the movement of modern society*.[3] This, I think, is the fundamental discovery of Marx's critique of political economy, which, in turn, allowed him to find the determinations of revolutionary class struggle as *immanent* in the historical movement of alienation itself. Moreover, we shall see that only on the basis of the unfolding of that determination is it possible to understand the limited transformative powers of the class struggle as a form of the reproduction of capital, its specific revolutionary powers behind its determination as the form of the latter's abolition and, finally, the mediation between the two.

In order fully to understand these determinations of the class struggle in capitalist society, it is evidently necessary to unfold the more abstract social forms which the latter presupposes. The following section, then, briefly reconstructs Marx's dialectical presentation of the determinations of capitalist social relations whose realisation leads to the constitution of the class struggle as a social form.[4]

---

[2] This oversweeping accusation of 'structuralism' hurled at anyone making the *critical* (as opposed to apologetic) point about the real constitution of capital as *alienated* subject has been a recurrent feature of the Open Marxist and other 'workerist' approaches. See, for instance, Bonefeld 1995, 2004 and 2014. In a recent article, Stoetzler makes a sharp response to that line of reasoning: 'When some humanist and workerist Marxists, in terms of a defence of subjectivity and agency, slander as "structuralists" those who emphasize the deplorable fact that we humans are ruled and overpowered by a structure, a form of our self-incurred immaturity or tutelage, they grant structuralism too much. The tradition that, following on from Marx, discovered and critiqued dichotomies in various aspects of the *capitalist* reality of human subjectivity – explicitly *not* of trans-historical human subjectivity – merely needed to spell out what was implied in Marx's suggestion that more and more aspects of human and societal reality are "really subsumed" to capital and its nuclear structure, the commodity form. The discovery that humans have, over the last two centuries, formed a dangerous and increasingly dominating social structure (totality) that urgently needs to be destroyed has nothing to do with structuralism. It was Marx who referred to value as an "automatic subject" (in the fourth chapter of *Capital* vol. 1; Marx, 1990: 255) that turns those to whose activity it owes itself into its "carriers", character masks, object-automatons; the point is that such a thing as an automatic subject, like the totality that forms it, should not exist. Emancipation means the de-automatization of subjectivity, a shared concern of the Enlightenment and all its inheritors' (Stoetzler 2012, p. 200).

Capital: The Materialised Social Relation That Takes Possession of the Species-Powers of Humanity

Capital as the Subject of the Circulation Process

The point of departure of Marx's analysis of the capital form is the result of the circulation of commodities, namely, money. As already mentioned, the circulation of commodities and its development engenders money in its functional determinations. The question arises, then, as to why it is necessary to start the exposition of capital with the money form. The reason can be found in the fact that Marx, as in the analysis of the commodity, starts the analysis of capital with an immediate observation, i.e. with capital 'as it appears at first sight'.[5] On a formal level, this point of departure reflects Marx's structuring principle of the different chapters around presentational nodes, with the capital form constituting a new stage in an exposition which, again, takes the immediate appearance of the social form under consideration as its starting point. And in its simplest manifestation capital presents itself as money. What needs to be investigated is, therefore, the specific nature of money as capital in contradistinction to money simply as such. Through this investigation, Marx presents the *analytic* moment of the exposition.

---

[4] Compared to the detailed discussion of Chapter 1 of *Capital* offered in the previous chapters of this book, and the one on Chapter 10 that makes up the focus of this chapter, my commentary on Chapters 4 to 9 will be admittedly sketchier. Thus, I will mostly limit myself to the summary of Marx's argument on its own terms, without critically bringing out many methodological or substantive issues underpinning his dialectical presentation. Similarly, I will not examine as many controversies among Marxists to which these chapters have given rise.

[5] Campbell (2013, pp. 154–5) also notes the isomorphism in the structure of exposition between Chapters 1 and 4 of *Capital*. Additionally, she rightly points out that this structure of the exposition generates the *appearance* of a lack of immanent unity (hence of a 'dialectical transition') between the commodity and money forms, on the one hand, and the capital form, on the other. As she also notes, this unity is given by the progressive 'autonomisation' of value in the course of the unfolding of the different functions of money (Campbell 2013, pp. 152–3; and 2005). Uncritically falling prey to the aforementioned appearance, some authors thus make a case for a *rupture* between the 'market form' and the 'capital form' (Bidet 2005, pp. 140–2; and 2007, p. 163; see also Saad-Filho 2002, p. 13). Reichelt (1995) somehow represents an intermediate perspective. Like Campbell, Reichelt agrees on the existence of an immanent unity between money and capital premised on the increasing independence of value. However, he considers that Marx argued along those lines in the *Grundrisse*, but not in *Capital*.

All that our immediate observation can tell us about this specificity is that it resides in the *form of its circulation*. Whereas the circulation of money as means of circulation can be represented with the form 'C–M–C, the transformation of commodities into money and the re-conversion of money into commodities: selling in order to buy', money that is transformed into capital circulates in the form of 'M–C–M, the transformation of money into commodities, and the re-conversion of commodities into money: buying in order to sell'.[6] However, behind these two distinct *forms* of circulation a difference of *content* lies hidden.[7] In the case of the simple circulation of money within the framework of the circulation of commodities, the content of the process is given by satisfaction of needs, that is, by individual consumption. In other words, the use value of the commodity is what constitutes the immediate object of the circuit.[8] In this sense, the aim of the cycle is external to the process itself. In the other case, on the contrary, the circuit 'proceeds from the extreme of money and finally returns to the same extreme. Its driving and motivating force, its determining purpose, is therefore exchange-value'.[9] This has a twofold consequence. In the first place, insofar as both extremes of the cycle M–C–M are identical, this process as such simply appears meaningless. Consequently, the extremes must be distinguished from each other in order for the circuit to acquire a purpose. Inasmuch as they are *qualitatively identical*, the only possible difference (and hence that which must become the aim of the process) is the *quantitative increase*. Thus, the adequate form of this process of circulation must necessarily be M–C–M′ where the initial sum of money (value in its concrete form of appearance) produces through its movement a larger amount of value, that is, a *surplus value*.[10] Money which circulates according to this form becomes determined as *capital*.[11] Secondly, and in contradistinction to what happens in the circuit C–M–C, the aim of the process is not external to it. The motive force – i.e. the valorisation of value – is internal to the process; it derives from the movement of circulation itself. Once the circulation of money as capital is complete, we return to the same point of departure: a quantitatively limited sum of money. And if the latter is to act as capital it must be thrown back into circulation. This means that the process of valorisation of value carries within itself the necessity of its own renewal, giving the process the character of being *formally* boundless.[12]

The exposition started with the circulation of capital as it appears in its immediacy and found the production of surplus value to be its content. The following point that needs to be accounted for is the source of the necessity of that movement. In other words, the phase of analysis still needs to go on in order to discover what sets into motion this process of multiplication of value. As with the analysis of the commodity, Marx presents his argument by first looking at apparent paths that the dialectical analysis could follow. Thus, it might seem that this process originates in the abstractly free activity of the possessor of money. However, as already shown by the analysis of commodity fetishism, through their free conscious and voluntary action the owners of commodities cannot but act as the personification of the social powers inherent in their commodities. Inasmuch as she/he is an alienated human being, the capitalist only realises through her/his apparently free action the immediate necessity of her/his capital.[13] The movement of value, although mediated by the subjectivity of the capitalist, is not grounded in her/his consciousness and will. Thus, Marx discovers that *the necessity of the process of circulation of money as capital comes from the automatic movement of value itself*.[14] In becoming capital, value – the materialised social relation of the private and independent individuals – turns into the concrete *subject* of the process of circulation of social wealth.[15] In turn, the commodity and money, the particular and the general mode of existence of mercantile wealth, become determined as transitory forms which value takes in its process of self-expansion. As Marx states,

> [V]alue is here the subject of a process in which, while constantly assuming the form in turn of money and commodities, it changes its own magnitude, throws off surplus-value from itself considered as original value, and thus valorises itself independently. For the movement in the course of which it adds surplus-value is its own movement, its valorisation is therefore self-valorisation [*Selbstverwertung*].[16]

[15] Robles Báez (1992) provides a useful discussion of the mediations involved in the constitution of capital as subject.

[16] Marx 1976g, p. 255.

The alienation of the human individual thus reaches a new stage. It is not only about a process of social production mediated by the value form of the product. Not even about one that simply has value as the direct object of the process of exchange. The objectified abstract labour represented as the exchangeability of commodities has taken possession of the potencies of the process of circulation of social wealth itself. This moment of the human life process is turned into an attribute of the life cycle of capital, which has the production of more of itself, i.e. its quantitative increase, as its only general qualitative determination.[17] This is where the formal specificity of capital as an *indirect*, hence *materialised*, social relation resides. Thus, the production of human life has ceased to be the content of the movement of social reproduction and has become the unconscious outcome of the production of surplus value, that is, of the *only* (alienated) content presiding over the movement of modern society.[18]

In my view, this is probably the most important *critical* insight of the fully developed Marxian critique of political economy and also the link with the so-called 'early writings': the discovery of the social constitution of capital as an autonomous and self-moving subject amounts the concretisation of the young Marx's account of alienated labour. Thus, unlike its first manifestation at the level of the commodity form, the activation of the autonomised regulation of social life no longer has the private individuals' apparently free decision to engage in the organisation of their production as its premise. Furthermore, it is not extinguished upon the completion of its mediating role in the cycle of metabolic exchange – that is, once the commodity leaves circulation and enters the sphere of personal consumption. Upon reaching the capital form, the automatism of the general social relation between private and independent individuals becomes the constantly renewed *premise and result* of the social metabolic process itself. The social relation between humans, existing in the form of the attribute of a thing, becomes *self-activating* and sets the 'human exchange of matter' into motion by itself, with the only aim of boundlessly expanding its magnitude.

Now, as Marx puts it in the *Grundrisse*, this 'twisting and inversion [*Verdrehumng und Verkehrung*]' of the general objectified form of social mediation into the self-moving subject of the process of human metabolism is 'not merely a *supposed one* existing merely in the imagination of the workers and the capitalists'.[19] On the contrary, it is a '*real phenomenon*',[20] unconsciously or spontaneously posited as 'socially-valid objectivity' by the human brain itself, when the general social character of labour is established behind the back of the privately undertaken activity of individuals. At least two important questions follow from this.

---

[17] Iñigo Carrera 2008, p. 12.

[18] The emphasis on 'only' will become clear in the discussion below.

[19] Marx 1993, p. 831, original emphasis.

[20] Ibid.

In the first place, insofar as from Marx's materialist perspective this social production process is not simply 'the reproduction of the physical existence of the individuals', but a 'definite form of expressing their life, a definite *mode of life* on their part',[21] there can be absolutely no aspect of human existence that does not become determined as an instance of this metabolic interaction inverted as an attribute of capital. However inverted in its form, this *is* the mode in which the materiality of human life exists. As a consequence, there can be no exteriority to its movement. The upshot of the constitution of capital as alienated subject is that *all* the determinations of the human life process will *really* prove to be material bearers of the former's self-expansion. From this point onwards, the exposition will show that individuals, *precisely* for being the *material* subjects of this process (rather than 'in spite of'), shall become fully *form-determined* as personifications of different determinations emerging out of the movement of value's self-valorisation.

In the second place, this means that capital, as self-valorising value, is not simply an 'abstract social structure of impersonal *domination*' over human beings.[22] It certainly is such a form of objective or impersonal subjection, but only as the concrete form taken by its essential character as a mode of 'articulation' of the social division of labour, i.e. a specific form in which society resolves the establishment of the material unity between social production and consumption. That the form of capital taken by this process entails its inversion into a *means* for an *alien purpose* does not change the matter. At stake here is first and foremost the material reproduction of human society and not a system of 'power or domination'.[23]

Yet, although at this stage of Marx's argument there are already elements which allow the reader to *infer* that capital turns into the alienated subject of human life *in its totality*, this unity is still to be concretely *posited* by the dialectical exposition. Certainly, the unfolding of the commodity and money forms reached a point in which, in the form of the movement of simple circulation as a whole, a first expression of such social unity became manifest. But that unity was only abstractly posited. As Marx states in those pages, that 'the scattered elements' comprising 'society's productive organism' attained 'qualitative and quantitative articulation' into 'the system of the division of labour' appeared as entirely haphazard.[24] On the other hand, as the exposition moved on to the inversion of simple circulation of commodities into the circulation of capital, that abstractly posited unity fell apart. In effect, Marx immanently discovers the general determination of capital as self-valorising value by reproducing in thought an *individual* cycle of money-as-capital. Both the fact that capital subsumes the content of social (re)production in its unity and the concrete form in which that unity is formally and materially established as its own alienated attribute, has not been systematically posited by the dialectical presentation. As a matter of fact, the gradual unfolding of this progressive subsumption of the materiality of the human life process under the movement of capital is what the rest of the three volumes of *Capital* are all about. At that stage, however, Marx only encountered the most abstract appearance of this total social process, which is the constitution of individual capitals as the subjects of their apparently autonomous respective cycles of valorisation in the sphere of circulation. Let us resume Marx's exposition from that point.

---

[22] Cf. Postone 1996, p. 30.

[23] Cf. Holloway 2002b and 2010.

Having discovered the generic essential determination of capital as self-valorising value, Marx's exposition turns to follow the concrete form in which this content, i.e. the production of surplus value, is realised. The analytic phase of the exposition thereby gives way to the synthetic stage, which consists in positively unfolding by means of thought the previously discovered self-movement of capital as the alienated subject of that process.

> As the dominant subject [*übergreifendes Subjekt*] of this process, in which it alternately assumes and loses the form of money and the form of commodities, but preserves and expands itself through all these changes, value requires above all an independent form by means of which its identity with itself may be asserted … Value therefore now becomes value in process, money in process, and, as such, capital. It comes out of circulation, enters into it again, preserves and multiplies itself within circulation, emerges from it with an increased size, and starts the cycle again and again.[25]

At this point, the exposition seems to face an impasse: the determinations developed thus far are revealed to be impotent to account by themselves for this process of multiplication of value. The law that governs the movement of the sphere of circulation – that is, the exchange of equivalents – is incapable of explaining the generation of a surplus value.[26] As Clarke succinctly puts it, this process

---

[24] Marx 1976g, p. 203.

[25] Marx 1976g, pp. 255–6.

> cannot take place within exchange, at least as so far developed, because exchange does not *create* value, it merely changes its form. It is certainly the case that unequal exchanges could take place, but such exchanges could not yield a *surplus* value, they can only redistribute a portion of an existing sum of value as gains and losses balanced out.[27]

Although having circulation as its point of departure and hence with this sphere as one of its moments, the process of value's self-expansion pushes beyond circulation itself. The movement of capital shows the necessity to find within the circulation of commodities a commodity whose use value for capital is to produce more value than it costs. The existence of the doubly free worker provides capital with this requirement.[28] As an independent human being, this worker can freely dispose of her/his individual productive powers.[29] However, insofar as she/he is deprived of the objective conditions in which to externalise her/his free subjectivity, she/he must give her/his labour power the form of a commodity to be sold on the market to the immediate personification of capital.[30]

What are the determinations of the commodity in its concrete form of the labour power of the doubly free worker? As any other commodity, labour power is a unity of value and use value. The former is thus determined by the socially necessary labour time required for the production of this commodity which, in this particular case, resolves itself into the production of the means of subsistence necessary to reproduce the physical and mental powers of the labourer.[31] The latter is nothing other than the actualisation of the productive capacities of the worker, i.e. labour.[32] As stated above, it is through the appropriation of the use value of this peculiar commodity that capital is able to valorise itself. The exposition must therefore develop the determinations of the process of consumption of labour power, which takes place 'outside the market'.[33] In this way, we will see in the next section how capital not only becomes the subject of the process of circulation of social wealth, but also turns into the subject of the immediate process of production.

[32] Marx 1976g, pp. 270, 274–5.

Capital as the Subject of the Immediate Process of Production

In order to valorise itself, then, capital has to take possession of the potencies of the human labour process. Through the movement of material production that at the same time produces the reified general social relation – value – capital is able to carry out its real valorisation, which, before this point, was only potential. At this stage of the presentation, in which capital takes the materiality of the labour process as a given presupposition (the *formal subsumption* of labour in capital), the only possibility to actualise capital's valorisation is to expand the amount of labour power productively consumed by extending the working day of the labourer beyond the hours of labour socially necessary to reproduce the value of labour power (which therefore becomes determined as necessary labour).[34] Thus, the secret of the immediate source of surplus value is revealed: its origin lies in the surplus labour that the labourers perform under the control of the capitalist to whom they freely sold their labour power at its value. Consequently, this surplus value becomes materialised in the product of labour which takes the form of the rightful private property of the capitalist.[35] In other words, the valorisation of capital takes concrete form through the exploitation of the productive powers of living labour. In this way, it determines the production of use values in the commodity form as a concrete form of the production of surplus value. From now on, the labour process becomes determined as the material bearer of the process of value's self-valorisation. In this unity, the immediate process of production becomes a process of production of capital.[36]

Although capital is essentially determined to be indifferent to any qualitative distinction other than the production of its quantitative increase, its material embodiment in the labour process produces its qualitative differentiation. It is clear that the production of use values, through which the production of surplus value takes place, necessarily involves the organic unity of labour power and means of production in order to put the labour process into motion.[37] However, the only portion of capital able to change its magnitude is the one that is materialised in labour power, which thus becomes determined as *variable capital*.[38] The portion materialised in the form of means of production lacks this capacity and hence negates the essential determination of capital of being an inherently variable magnitude. The value of the means of production is transferred by living labour to the product and just reappears in the same magnitude.[39] Capital is thus negated simply as such to affirm itself as *constant capital* which, however, constitutes a necessary condition for the affirmation of its power of self-valorisation.[40] In short, the valorisation of capital can only take concrete form through its qualitative differentiation between variable and constant capital.

Valorisation of Capital and Class Struggle

The differentiation of the total capital advanced into constant and variable capital reveals to us that, on condition that a part of capital does take the concrete shape of means of production in the right proportion, the actual change of magnitude in which the valorisation process consists immediately springs from the part of capital materialised in the form of labour power.[41] The inner measure of the degree in which capital self-valorises thus becomes determined by the ratio of the surplus value produced to the variable capital.[42] This is what Marx terms the rate of surplus value. From the perspective of its material content, the rate of surplus value expresses, in a specifically capitalist form, the relation between surplus labour and necessary labour.[43] The latter is the part of the working day necessary to produce the means of consumption which allow the reproduction of the labour power of the workers. The former is constituted by the labour expended during the part of the working day which goes beyond the labour time necessary for the reproduction of labour power.

With the determinations unfolded thus far, the value of labour power – hence the magnitude of variable capital – is a given quantity for capital's process of valorisation.[44] In effect, with the productive subjectivity of the wage labourer and the material forms of the objective conditions of the process of production as an external presupposition, the means of subsistence which enter into the consumption bundle of the labourer and the productivity of labour constitute a given condition for capital's production of surplus value. Thus, if we look at the circuit of capital's valorisation in its purity – i.e. assuming that the law of equivalence regulates exchange – the value of labour power appears to constitute an external limit to the realisation of capital's essential determination as self-expanding value. Under these circumstances, the degree of capital's valorisation depends on the length of the working day, which, unlike the value of labour power, appears in its immediacy to be a variable quantity with no inherent limit to its extension apart from the absolute one constituted by the 24 hours of the day.[45] However, this appearance vanishes as soon as we consider the materiality of the process of consumption of labour power; the physical determinations of the expenditure of labour power already pose a limit to the prolongation of the working day. In addition, the very reproduction of labour power in the conditions determined by what Marx calls 'the general level of civilisation' – and which, again, are external to capital at this stage of the presentation – requires that a part of the day is spent on the satisfaction of the 'intellectual and social requirements' of the labourer.[46]

[42] Marx 1976g, p. 324.

[43] Marx 1976g, p. 325.

It is only at this juncture that Marx, for the first time in the dialectical exposition of the critique of political economy, shows the necessity of the class struggle as a capitalist social form. In Marx's exposition, the class struggle is presented only as the necessary concrete form in which the physical and social limits to the extension of the working day are set. However, a closer scrutiny of Chapter 10 of *Capital* makes clear that its essential *simplest* determination is actually more general: *the historically specific determination of the class struggle in the capitalist mode of production consists in being the necessary concrete form of the buying/selling of the commodity labour power at its value.*

In order to appreciate this, it is fundamental to highlight an aspect of Marx's presentation which could otherwise appear as capricious and extrinsic to the concrete determinations we had before us, namely, the calculation of the *daily* value of labour power, which is the one that ensures the reproduction of labour power throughout the whole of a worker's working life.[47] What Marx intends to show by means of that calculation is that the excessive prolongation of the working day actually involves the payment of labour power below its value. Hence, the resistance to that extension in the productive consumption of labour power beyond a socially determined 'normality' is only a concrete manifestation of the broader question about the realisation of the full value of labour power.[48] This is illustrated by Marx through the words of that fictional average wage worker who, in giving the reasons for his refusal to let the capitalist impose her/his will on the determination of the length of the working day, claims: 'I demand a normal working day because, like every other seller, I demand the value of my commodity'.[49]

---

[44] Marx 1976g, p. 340.

[45] Marx 1976g, p. 341.

[46] Ibid.

[47] Marx 1976g, p. 343.

The above quote has crucial implications. It shows without ambiguity that, in opposition to the claims of many contemporary Marxists, for Marx the *simplest* social determination of the class struggle is not to be the antagonism between two different and irreconcilable principles of organisation of social life: the valorisation of capital and the production for human needs, or the 'logic of abstract labour' and the 'logic of concrete labour'. In this sense, the resistance of workers to the extraction of surplus value does not immediately express (however 'contradictorily') the absolute opposite of the general social relation through which they reproduce their lives, namely, the valorisation of capital.[50] On the contrary, I think that Marx's discussion of the length of the working day in Chapter 10 of *Capital* implies exactly the opposite: it presents the struggle of workers as a concrete form of the movement of alienated social life as any other form of their life activity. In other words, though clearly an 'endemic' reality of the capitalist mode of production, the class struggle is not *ontologically* but *socially* constitutive of capitalism, since capitalist and worker, *as owners of commodities* (not as embodiments of ontologically different principles of social reproduction), personify social determinations of the process of valorisation of capital whose realisation is antagonistic.[51] Let us return to Marx's text in order to substantiate this point.

---

[48] See the appendix for a discussion of the meaning and determination of the 'normality' involved in the purchase of labour power at its value.

[49] Marx 1976g, p. 343.

[50] For instance, the 'recalcitrance of use value' (Arthur 2001b) to the pure dialectic of the value form, 'a world of pure form empty of content' (Arthur 2001a, p. 33). One could argue that the essentials of this train of thought can be found, in different guises, in various traditions of unorthodox Marxism. See, among others, Cleaver 1979 and 1992; Albritton 2003; Radical Chains Collective 1993; Kay and Mott 1982; Dunayevskaya 1988; Dinerstein 2002. The difference between these alternative versions resides in the specific determination in which they locate this radical 'otherness' to capital which sets into motion its abolition. They all seem to have in common the view that the revolutionary negation of capital is not an alienated necessity of the accumulation of capital itself, engendered by the latter's own historical movement, instead of being its abstract negation. And notice that I mean this in the profoundest 'dialectical' sense of 'intrinsic connection'. That is, not just in the banal sense that the revolutionary action is 'produced' by capital because the proletariat 'reacts' to the miserable or inhuman conditions to which capital condemns it. Thus posed, the relation is completely external. The question is: which concrete historical potentiality of the valorisation of capital – the *only* present-day *general* social relation – carries within itself, as its only form of realisation, the necessity of its own annihilation through the revolutionary action of the working class? At the other extreme of those 'ontologisations' of the class struggle lies its 'biologisation' by Kautsky, for whom the class struggle was simply a human instance of the natural struggle for survival characterising the relation among species. See Kautsky 1978, p. 201.

Marx's starting point in his presentation of the determinations of the class struggle over the length of the working day is the individual direct relationship between capitalist and worker, whose antagonistic character, far from constituting the abstract negation of the indirect social relations regulating the circulation of commodities, springs from the realisation of those laws themselves. The capitalist, acting as the personification of the necessity of her/his capital, wants to extend the length of the working day as much as possible. As a rightful buyer of commodities, she/he wants daily to extract as much use value as possible from the commodities she/he buys;[52] among them, the labour power of the wage labourer. Actually she/he is forced to do so by the competition from other individual capitals that mediates her/his determination as personification of the most immediate necessity of capital: the production of surplus value.[53] The worker wants to limit that daily extraction. Actually she/he is compelled to do so if she/he wants to preserve her/his productive attributes in the conditions needed to be able to sell her/his labour power in the future. In other words, if she/he wants to get paid the full value of the latter throughout the course of her/his productive lifetime. As we have seen, the struggle of the worker over the length of the working day is actually a concrete manifestation of the struggle over the realisation in full of the value of labour power.[54]

---

[51] It could be argued, following Shortall (1994, Chapter 5) – building on insights originally developed by Negri in *Marx Beyond Marx* (1991) – and Lebowitz (2003), that my reading of Marx's presentation of the class struggle in *Capital* is perfectly accurate but only because Marx's account itself is one-sided and/or incomplete, leaving the struggles of wage labourers which go beyond their determination as 'variable capital' out of the picture. Although these authors also give the class struggle an ontological foundation, they differ from those referred to above, insofar as they recognise that was not Marx's formulation, although it should have been.

[52] Marx 1976g, p. 342.

[53] Marx 1976g, p. 381.

[54] Hence, we can see now that every circumstance affecting the reproduction of labour

Thus, Marx concludes, the very operation of the *indirect* laws of commodity exchange leads to equally rightful but antagonistic stands on the length of the working day. The resolution of this antinomy makes the valorisation of capital take the concrete form of a *direct* social relation of *force*:

> There is here therefore an antinomy, of right against right, both equally bearing the seal of the law of exchange. Between equal rights, force decides. Hence, in the history of capitalist production, the establishment of a norm for the working day presents itself as a struggle over the limits of that day, a struggle between collective capital, i.e. the class of capitalists, and collective labour, i.e. the working class.[55]

The point to note here is that although Marx claims that that direct social relation is actually a class relation, the determinations unfolded thus far do not show any necessity for such transition from the individual antagonism between capitalist and worker to its constitution as *class* struggle. In reality, that observation is at this stage of an external character, an anticipation of the actual presentation of the determinations of the valorisation process that make it take the form of an antagonism between social classes. Marx unfolds this presentation of the essential determinations of the class struggle through a very long 'historical sketch' of the particular forms through which the former acquired concrete existence. Here, I shall concentrate on the general aspects of the determinations at stake, that is, I shall attempt to capture from Marx's account the contradictory tendencies of capital's valorisation process as such without reference to the concrete forms taken in the history of England as described by him.[56]

---

power – such as the intensity of labour, the wage, health and safety of working conditions, and so on – is a concrete expression of the question of the buying/selling of labour power at its full value.

[55] Marx 1976g, p. 344.

[56] On the dialectical-methodological significance of the notion 'historical sketch', see the seminal contribution by Müller and Neusüss to the so-called 'German State Derivation Debate' (Müller and Neusüss 1975). In that text, these authors highlight very well the need for concrete empirical study to see how the general determinations of capital accumulation unfold in the course of history in order to avoid the twin shortcomings of both an unmediated 'application' of the latter which would lead to a 'dogmatic history', and the abstract empiricism of sociology and political science. More generally, Müller and Neusüss's reconstruction of Marx's argument in the chapter on the working day is still one of the best accounts to date. Marx himself concisely presents the general determination

Marx organises his exposition by sketching out the way in which opposing tendencies regarding the length of the working day asserted themselves in the course of the movement of the history of the capitalist mode of production. Initially, he shows that a tendency to the brutal extension of the working day, which overstepped all traditional limits inherited from pre-capitalist social forms, made its way through history. In its general determination, this roughly corresponds to unchecked imposition of the will of the immediate personifications of capital in their voracious search for the utmost valorisation of their individual capitals, before 'the working class, stunned at first by the noise and turmoil of the new system of production, had recovered its senses to some extent' and 'began to offer resistance'.[57] In other words, the realisation of that tendency in its purity manifests the determinations of the valorisation process as they take shape without the constitution of the sellers of labour power as a class, i.e. through the individual antagonistic relationship they establish with the buyers of the only commodity they own, as discussed above. Under these circumstances, the respective power of buyer and seller of labour power is systematically biased towards the capitalist. Thus, if between equal rights, force decides, there will be a systematic tendency for the immediate personifications of capital to impose their will regarding the duration of the working day. Which means, as we have seen, the strife for 'the full 24 hours, with the deduction of the few hours of rest without which labour-power is absolutely incapable of renewing its services'.[58] Whilst the capitalist could survive without buying the labour power of any particular labourer, the latter faces the sale of her/his labour power, which is her/his only general social relation, as an immediate necessity. Thus, in the desperate attempt to establish her/his general social relation, the worker faces the competition of other individuals who can only personify the commodity form of their labour power. Although at this stage it cannot but be an external reflection, Marx points out that even immediate observation suffices to see how the very movement of the alienated regulation

---

at stake 'in its purity' – i.e. without its particular realisation in the course of the history of capital accumulation in England – in the preparatory *Manuscripts of 1861–3* (Marx 1988, pp. 180–5). As a matter of fact, the addition of a historical narrative to illustrate the systematic exposition of the general determination already developed by 1861–3 was not part of Marx's original plan. Thus, in a letter to Engels from 10 February 1866, he reports that he decided to elaborate 'the section on the "Working Day" from the historical point of view, which was not part of my original plan' because his poor health conditions prevented him from making progress 'with the really theoretical part' (Marx 1987b, p. 224).

[57] Marx 1976g, p. 390.

[58] Marx 1976g, p. 375.

of social life engenders the existence of a surplus population relative to the needs of capital's valorisation process, thus making evident that not all workers will be able to sell their labour power and thereby placing them in a relation of exacerbated competition. Hence the capitalist knows that she/he will always find a worker willing to sell her/his labour power, however long the working day might be:

> What experience generally shows to the capitalist is a constant excess of population, i.e., an excess to capital's need for valorization at a given moment, although this throng of people is made up of generations of stunned, short-lived, and rapidly replaced human beings, plucked, so to speak, before they were ripe.[59]

Marx then goes on to show the consequences of the pure operation of this tendency for the lengthening of the working day when the fixation of its limits is left to the unilateral action of the immediate personifications of capital, namely, the impossibility of workers to reproduce their labour power in the very conditions that the valorisation of capital demands from them, which means, sooner or later, the impossibility of reproducing labour power as such.

> By extending the working day, therefore, capitalist production, which is essentially the production of surplus-value, the absorption of surplus labour, not only produces a deterioration of human labour-power by robbing it of its normal moral and physical conditions of development and activity, but also produces the premature exhaustion and death of this labour-power itself.[60]

More generally, this implies that when considered at the level of the individual antagonistic relationship between capitalist and worker, the valorisation of capital inevitably leads to a tendency for labour power to be sold *systematically below* its value. However appealing this might be to the voracious appetite for an extra surplus value of the individual capital, this *immediate* necessity goes against the *mediated* necessity of the reproduction of the valorisation of capital as such to prevent the productive attributes of labour power, the one and only *direct* source of surplus value and hence of self-expansion, from exhaustion. Marx points this out by looking at this same phenomenon from another angle, i.e. by commenting on what would happen if labour power was consumed during an unnaturally prolonged working day:

---

[59] Marx 1976g, p. 380.

[60] Marx 1976g, p. 376.

> If then the unnatural extension of the working day … shortens the life of the individual worker, and therefore the duration of his labour-power, the forces used up have to be replaced more rapidly, and it will be more expensive to reproduce labour-power … It would seem, therefore, that the interest of capital itself points in the direction of a normal working day.[61]

It is this other necessity of the valorisation of capital that takes shape through the antagonistic will of the worker, who tries to limit her/his conscious and voluntary subjection to the will of the capitalist in the immediate production process. And this is what gives rise to the opposite tendency of the valorisation of capital regarding the length of the working day, whose concrete realisation takes the form of the struggle of workers as a class. Marx illustrates this by showing how only the long and protracted resistance of workers eventually led to the intervention of the capitalist state, which, in the alienated form of a law, imposed the direct general regulation of the extensive quantitative limit to the productive consumption of labour power by individual capitals. Seen from the perspective of the worker, this appears as the only way of securing her/his material and social reproduction in its capitalist form, that is, of getting paid the full value of labour power. And she/he can only succeed at this – on average, through the cyclical oscillation of the wage around the value of labour power – by establishing a relation of conscious co-operation with the rest of the workers in order to sell their labour power as a directly collective force. The general relation of competition among sellers of labour power is thus realised in the form of its self-negation, i.e. by taking the form of a relation of solidarity.[62] Hence the social constitution of antagonistic *class* wills or the necessary concrete form of *class struggle* taken by the reproduction of the alienated existence of social life.

---

[61] Marx 1976g, p. 377.

[62] Here we have the same point that the young Marx made against Proudhon that I commented upon in the first part of the book, namely, that co-operation or solidarity is not the abstract opposite of competition, but rather its necessary concrete form when labour power becomes a commodity. However, in *Capital* the same conclusion is reached by Marx after unfolding all the determinations presupposed by it, thus eliminating the traces of externality in the relation between those two social forms contained in his presentation in *The Poverty of Philosophy*.

> For 'protection' against the serpent of their agonies, the workers have to put their heads together and, as a class, compel the passing of a law, an all powerful social barrier by which they can be prevented from selling themselves and their families into slavery and death by voluntary contract with capital.[63]

Thus far I have developed the textual reconstruction of the simplest determinations of the class struggle in the capitalist mode of production, as they derive from their systematic place in Marx's dialectical presentation of the critique of political economy. As the above quote from *Capital* makes clear, in its simplest and most general form, the class struggle carries no content other than the establishment of the conditions for the preservation and reproduction of the productive attributes of workers as wage labourers. That is, it is the necessary form of the buying/selling of the commodity labour power at its full value. More generally, this implies that the determinations implicated in the mere existence of labour power as commodity (or the merely *formal subsumption* of labour to capital) do not give the class struggle the transformative potentiality to go beyond the capitalist mode of production.[64] In this simple determination, the political action of the working class is merely determined as a concrete form of the *reproduction* of capitalist social relations.[65] Although for the first time in this reconstruction of Marx's reproduction of the concrete by means of thought, we faced the necessity of capitalist social life to take the form of a political action of the working class, nothing in this journey put us before the necessity of the abolition of capital or, *a fortiori*, of the political action of the working class as its concrete form.[66] The search for the determinations of revolutionary subjectivity must therefore proceed into even more concrete determinations.

---

[63] Marx 1976g, p. 416.

[64] In an earlier presentation of the argument which eventually appeared in *Time, Labor and Social Domination*, Postone made a similar point from his own idiosyncratic perspective. See Postone 1978, pp. 781–3, where he refers to this determination as involving 'class-constituting consciousness', as opposed to properly revolutionary consciousness, which he terms 'class-transcending consciousness'.

[65] In contrast to my reading, Psychopedis (2005, pp. 80–1) sees in the implementation of legal norms to regulate the working day an immediate expression of the 'logic of revolution' already at work. Writing from a broadly understood 'Open Marxist' perspective, Psychopedis grounds revolutionary subjectivity in the affirmation of a generic human materiality that exists in the mode of being denied, i.e. in an alienated social form. On this score, his argument does not substantially differ from that of Bonefeld discussed in the previous chapter. However, Psychopedis gives the overall argument an idiosyncratic twist. In his own words, 'the dialectical presentation is not simply a matter of contrasting the "bad form" with the "good contents"' (Psychopedis 2005, p. 80). Instead, it is a matter of 'the demonstration that in capitalism the social forces of production become forces of destruction', so that 'this form poses a real threat to the continued existence of this materiality' (Ibid). The ground of the revolution is thereby seen as residing 'in the attempt of preserving the conditions of life' in the face of capitalism's destructive tendencies and the ultimately *unstable* character of the capitalist state's direct regulation of the material

---

conditions of social reproduction, insofar as 'in the long run capital cannot tolerate regulations that reduce the profit margin' (Psychopedis 2005, p. 81). As compared to Bonefeld's approach, this train of thought has the merit of acknowledging that the foundation of revolution is not contained in the *simplest* contradiction between human content and reified form, but in a *more concrete determinate expression* of that contradiction. The further dialectical exposition of form determinations beyond commodity fetishism thus becomes more meaningful for the discovery of the social foundation of the emergence of the revolutionary subject. Nevertheless, Psychopedis still relapses into grounding revolutionary subjectivity in an element which is external to the contradictory self-movement of the capital form: revolution is seen as the affirmation of an abstractly self-determining struggle for society's survival in response to capital's destructive barbarism. Thus, the necessity of revolution is not *immanently* carried by the capital form; instead it is carried by the reproductive conditions of an abstractly conceived 'society' lacking in form determinations, whose existence is 'thwarted' by its subsumption under the capital form. In the end, Psychopedis's account comes down to a more sophisticated version of Luxemburg's 'socialism or barbarism', i.e. of the classical Marxist view of socialism as the 'only salvation for humanity' in the face of 'war, famine and disease' (Luxemburg 1971, p. 367).

[66] In order to avoid misunderstandings, let me note that I do not restrict the determination of the class struggle as a *political* action to the conquest of state power or to an action involving demands directed at the state. The political determination of the class struggle springs from the *objectively general* scope of the antagonistic direct social relation between capitalists and wage workers (Iñigo Carrera 2008, pp. 267–8). As Marx puts it in a letter to Bolte, 'a *political* movement' is 'a movement of the *class*, with the object of enforcing its interests in a general form, in a form possessing general, socially coercive force' (Marx 1965). Whether that general determination is manifested in the form of fragmented 'economic movements' or an immediately general 'political movement' is something which cannot be addressed at this level of abstraction. What should be clear is that the determination of the class struggle as the form of the sale of labour power at its value does not simply involve the 'trade union' form of the class struggle. Concomitantly, neither does that simplest determination of the class struggle mean that it will always be realised through the development of mere 'trade union consciousness'. In other words, that determination may well manifest itself in *apparently* extremely radical or militant forms of the class struggle. In brief, what is at stake in this discussion is the simplest *content* of the class struggle regardless of its *concrete forms*. The confusion between content and concrete form of the class struggle is precisely what lies at the basis of the orthodox rigid separation between economistic and political consciousness of the working class.

This will be the subject of the next chapter. For the moment, I would first like to further explore the implications of this determination of the class struggle as a concrete form of the valorisation of capital.

Class Struggle and the Concrete Subject of the Movement of Capitalist Society

The form of class struggle taken by the movement of capitalist society evidently implies the obstruction of the ceaseless movement of valorisation that constitutes the most general determination of capital as the alienated subject of that process. This could raise the question as to whether this determination entails the absolute negation of capital as the subject of the valorisation process, thus reducing the latter to a concrete form of the class struggle.[67] Or, as commented above, it could lead to the conclusion that since workers' struggles press in the opposite direction to the immediate necessity of capital personified by the capitalists, they must be expressing a different principle of social reproduction from the valorisation of capital. Thus, although it might be true that capital is the subject of the valorisation process, this does not exhaust the 'logic of capitalism as a whole', which is said to comprise the antagonistic unity between the political economy of capital and the political economy of wage labour.[68] Each pole of that unity in opposition is seen as the concrete subject of its own production process and the realisation of their respective goals is seen as repelling the other – hence their antagonism. However, each side needs the mediation of the other for its own reproduction – hence their unity.[69]

There is no doubt that the interruption of the valorisation process constitutes the immediate negation of the most general necessity of capital as subject. However, as my reconstruction of Marx's argument has shown, the form of class struggle taken by the movement of society is actually a determination of the *affirmation* of capital as subject, albeit through *its own negation*. In other words, my point is that the social form of class struggle does not abstractly negate capital's condition of alienated subject, but only expresses the necessarily *contradictory* character of its own movement as one of *affirmation through self-negation*. What the class struggle does negate is the condition of subject of the process of valorisation to what up to that point *appeared* to be the bearer of that social determination, namely, the *individual* capital. The fact that the actions of individual capitals undermine the reproduction of the very direct source of their self-expansion thus makes clear that the production of surplus value is an attribute that exceeds the former's potentiality as particular private fragments of social labour. However, this does not reveal the class struggle as the self-determining force behind the movement of capitalist production, nor does it unveil the emergence an antagonistic principle of organisation of social life other than the valorisation of capital, which would be, in turn, incarnated in the working class.[70] Rather, it only shows that the production of surplus value is a potentiality of the alienated existence of social labour *in its unity*. In other words, Marx's exposition of the social form of class struggle evidences, for the first time in the pages of *Capital*, that the concrete subject of the process of valorisation – and hence of the movement of alienated social production – is the *total social capital*.[71]

---

[67] Cf. Bonefeld 1995.

[68] Lebowitz 2003, Chapters 4 and 5.

[69] Lebowitz 2003, pp. 75–6.

The class struggle, then, is the concrete form of development of the antithetical social necessities generated by this alienated total social subject in its process of valorisation. The fact that the most *immediate* necessity of capital is the *formally boundless* quantitative expansion of the surplus value produced does not imply that the limitation to that expansion is not a necessity of its own reproduction. However, we have seen that the latter is a *mediated* necessity, this being the reason why it cannot be realised through the actions of capital's *immediate or positive* personifications – i.e. the capitalists – and why it can only be *negatively or mediatedly* personified by the working class in its struggle against the bourgeoisie. Hence, when the workers struggle, they do not cease to be subsumed to the movement of reproduction of alienated social life. On the one hand, their subjectivity does not act according to an abstractly different 'logic' from that of capitalist commodity production. As we have seen, the relation of conscious solidarity established by workers in their opposition to the positive personifications of capital is in complete accordance with the specific form of their social being, that is, with their determination as private and independent individuals and, more precisely, as commodity sellers.[72] Their conscious co-operation in the form of a political action is not the unmediated expression of a relation of solidarity between *human beings as such*. Rather, it is such a solidaristic relation mediated by the workers' condition as alienated human beings, that is, as *personifications*. In acting in this way without being aware of their determination as attributes of the total social capital – i.e. *in seeing themselves as naturally free* but under an external compulsion which thwarts the affirmation of that personal freedom – they unconsciously personify a necessity of the *reproduction* of their alienated general social relation, albeit one which is evidently antagonistic to that personified by the capitalist.[73]

---

[70] De Angelis 1995 and 1996.

[71] From a textual point of view, Marx does not *name* the total social capital at this stage. Instead he refers to an abstract 'society', acting through the state as the representative of its general interests (standing as an external force over the particular interests of social classes), as the subject that compels capital to take 'account of the health and life of the worker' (Marx 1976g, p. 381). However, as Caligaris remarks (2012, p. 80), for Marx 'society' in the abstract is a meaningless entity. For him, society always exists in a specific historical form. On the other hand, in its general determination, society is not an abstraction existing over and against human beings, but is the general social relation through which the immanent social unity of their individual actions is posited. But insofar as this unity in capitalism operates behind the backs of individuals (hence of social classes), it appears as an external power vis-à-vis human beings. In the chapter on the Working Day, this alienated social unity is posited in its directly political form as the *state*. But its economic content (material reproduction in its value form) is not yet fully posited. A first instance of this positing eventually occurs in the chapter on simple reproduction. In my view, this is why Marx decides at that particular stage explicitly to name the total social capital as the concrete alienated subject of material reproduction in its unity. Retrospectively, it then becomes clear that the 'society' of Chapter 10 was actually the total social capital, and the state was the latter's general political representative (Caligaris 2012; Iñigo Carrera 2012).

Once Again, the Question of the Dialectical Method

At this juncture we can now appreciate the methodological significance of this discussion. For the aforementioned notion that the political action of the working class ultimately expresses social necessities radically opposed to those of the accumulation of social capital rests on what we have seen in the first part of the book as the *logical representation* of the specific movement of affirmation through self-negation constituting the determination of social forms, in the form of a unity of two immediate affirmations. Thus, when the mediated necessities of the total social capital are only grasped in their immediate concrete form of existence as simple and abstract 'human' needs of the working class, the development of the latter appears as a social process regulated by different 'laws' from those of the reproduction of the valorisation of the total social capital itself. This is a process that furthermore appears to stand in external opposition to the needs of the total social capital, one-sidedly reduced to those immediate ones that are personified by the capitalist class. Moreover, this appearance is reinforced by the form taken by the circuit of reproduction of labour power, which has the satisfaction of needs – hence the production of the worker – as its immediate result ($\text{LP–M–C} \ldots \text{P}_{\text{LP}} \ldots \text{LP}^{*}$; C–M–C^{*} in its most general form).[74] From this, the conclusion is drawn that this circuit expresses a different existential logic or social ontology from that of capital's valorisation process (M–C ... P ... C′–M′) and, according to some authors, that it thereby provides the social basis for the revolutionary subjectivity of the proletariat.

---

[72] Cf. Postone 1996, pp. 314–23.

[73] It follows from this that the distinction between capital-reproducing and capital-transcending consciousness does not revolve around that between 'trade-union' or 'economic' consciousness, and 'political' or 'socialist' consciousness. It is a matter of whether wage workers are conscious of their own alienation in the totality of its determinations, or whether they fall prey to the appearance of natural human freedom taken by their subordination to the total social capital.

In a nutshell, the general question at stake concerns the social determinations of both the needs of workers and the social form of their satisfaction. Thus, it may seem that, at least outside the process of production, i.e. in the sphere of individual consumption, the freedom of the wage labourer ceases to be a concrete form of her/his alienation. There is no doubt that outside the immediate process of production, and in the process of individual consumption through which labour power is reproduced, wage labourers freely pursue their own goals. Unlike the subordination to the capitalist's despotic will reigning in the immediate process of production, in the process of reproduction of labour power the wage worker appears to be freely acting as a 'being-for-self' and not 'for another', as 'one who approaches capital as a *means*, a means whose end is the worker for self'.[75] And yet, since the selling of labour power as a commodity is the general social relation regulating the reproduction of the worker's life, she/he must apply that free consciousness and will materially to produce her/his productive subjectivity in the conditions determined by the autonomised movement of social life as an attribute of the product of social labour – i.e. by the production of surplus value. The second sense of her/his freedom (the divorce of the labourer from the means of production) means that she/he can reproduce her/his natural life only by producing her/his attributes as a human individual in the material and moral conditions in which *the total social capital* needs her/him in order to produce surplus value; that is, by producing herself/himself as an adequate personification of the only commodity she/he owns. Certainly, in this process of self-production, the wage labourer is not subsumed to the cycle of valorisation of the *individual* capital and, therefore, she/he does not act for this or that particular 'other'. However, the whole gist of Marx's arguments aims at showing that precisely through this free individual consumption (which certainly can only be secured by the class struggle), the worker reproduces her/his subsumption to the total social capital, which thereby affirms itself as the concrete subject not only of the processes of production and circulation of social wealth, but also of the process of individual consumption.

---

[74] Where LP is the abbreviation of labour power and P_{LP} corresponds to the process of reproduction of labour power through individual consumption.

[75] Lebowitz 2003, pp. 71–2.

> The individual consumption of the worker, whether it occurs inside or outside the workshop, inside or outside the labour process, remains an aspect of the production and reproduction of capital … The fact that the worker performs acts of individual consumption in his own interest, and not to please the capitalist, is something entirely irrelevant to the matter … The maintenance and reproduction of the working class remains a necessary condition for the reproduction of capital. But the capitalist may safely leave this to the worker's drive for self-preservation and propagation.[76]

In short, the individual consumption of the labourer is neither for the benefit of individual capital nor for herself/himself, but for the total social capital. The cycle $\text{LP}–\text{M}–\text{C} \ldots \text{P}_{\text{LP}} \ldots \text{LP}^{*}$ is a moment of the accumulation of capital – and hence of capital's 'goal' of self-valorisation – as any other aspect of alienated social reproduction.[77]

As we can see, there is no exteriority to the alienated social relations of capital. Therefore, any revolutionary will and actual *material powers* the workers might have to go beyond these alienated social relations can only derive from this complete subsumption of humanity to capital's 'principle' of valorisation. With the determinations unfolded thus far, the class struggle embodies no transformative potentiality other than being the form in which labour power is sold at its value and, therefore, a form of the reproduction of the alienation of human productive powers in the form of capital. And yet, even in this simple form, the class struggle puts us before a determination which, although unable to account for the *content* of the necessity for the abolition of the capitalist mode of production, already sheds light on the reason why the latter can only have a political action of the working class as its *form*. I am referring to the fact that the class struggle is the most general form taken by the organisation of social labour through a conscious and voluntary *collective* action in capitalist society.[78] This is because determining the value of labour power entails the determination of the way in which the total labour power of society is allocated into its different useful forms; in this case, the general division between necessary labour and surplus labour. And we have seen how this is resolved in the capitalist mode of production through the establishment of a direct relation of solidarity among workers in order to develop a consciously organised collective action. On the other hand, the annihilation of capital through the creation of the society of the consciously – hence concretely free – associated producers precisely consists of a social action of such a nature. Evidently, the latter is a social action which no longer expresses the total social capital's need for labour power being sold at its value. Rather, it expresses the historically determined necessity to move forward in the development of human productive subjectivity in a form which negates capital's existence as the general social relation reproducing human life, namely, by giving the materiality of social life the form of its conscious general organisation as an attribute borne by each of the associated individuals. But the point is that the *material content* of this transformation is achieved in the *form* of the political action of the (self-abolishing) proletariat, only because the latter already contains, within its simplest form, the potentiality of being the necessary concrete form taken by the general conscious organisation of social labour as a moment of the reproduction of the total social capital.[79]

---

[76] Marx 1976g, p. 718.

[77] As a matter of fact, we shall see in the next chapter, when discussing large-scale industry, that concerning the productive attributes of workers (hence the satisfaction of their needs), the interests of individual capitals might clash with the needs of the reproduction of the total social capital, which is why the latter must be personified by the struggle of wage workers as a class. *Pace* Arthur, the essential implication of this is that labour power is *not* 'an external condition of capitalist production'. See Arthur 2006, p. 92.

---

[78] Iñigo Carrera 2008, p. 15. By virtue of this character as a conscious collective action, the class struggle becomes determined as a *political form* of social relations, which mediates the general *indirect* relation through the value form (determined as the *economic form* of social relations). The emergence of the class struggle and the distinction between individual capitals and the total social capital are therefore at the basis of the historically specific differentiation of the capitalist social relations into economic and political forms. This is the rational kernel of the best contributions to the so-called 'German State Derivation Debate' (Müller and Neusüss 1975; Alvater 1973), and to its reception within the Conference of Socialist Economists in the UK (Clarke 1988 and 1991b). My own views on the nature of the state are more directly informed by Iñigo Carrera (2012), insofar as he grounds the differentiation of economic and political forms of the capital relation in a manner which is consistent with the determination of the total social capital as alienated subject. Thus, although the antagonistic character of the class relation is a necessary form taken by the reproduction of the total social capital, it disrupts the fluidity of the former's valorisation. The establishment of the general unity of social labour must therefore take shape through a further objectified form of social mediation, the state, which confronts commodity owners (the personifications of money-as-capital and of the commodity labour power) as an apparently external power with the authority and capacity to establish the overall direct regulation of their antagonistic social relations. The state thus develops as the most concrete political form that embodies the direct organisation of the unity of the conditions of social reproduction in its alienated capital form. That is, it is a concrete form of the essentially indirect social relations through the valorisation of capital. By virtue of this content, the state becomes the *general political representative of the total social capital.* Far from enjoying 'autonomy' (relative or otherwise), state actions are a necessary mode of realisation of the contradictory content of the economic mode of existence of capitalist social relations. In other words, class struggle and state policies are not to be conceived of as independent, self-subsisting factors that externally modify or influence the workings of the 'law of value'. Instead, they need to be grasped as necessary modes of motion through which the law of value further unfolds beyond the strictly economic forms immediately springing from the indirect nature of the social relations of capitalist production.

Appendix: Some Marxist Controversies over the Determination of the Value of Labour Power[80]

As we have seen, Marx argues that the value of labour power is *determined* by the socially necessary labour time required to produce this particular commodity, which in this case comes down to the socially necessary labour time required for the production of the use values which must be consumed in order to (re)produce the physical and intellectual productive powers of the wage worker in 'normal' conditions. On the other hand, my close reading of Marx's presentation of the establishment of a normal working day has shown that the *realisation* of the full value of labour power must necessarily be *mediated* by (i.e. *takes concrete form* in and through) the class struggle. Yet, these two aspects of Marx's account of the determination of the value of labour power have not remained without controversy among his followers. Thus, some Marxist scholars have either challenged their validity or offered an alternative reading which in my view parts company with Marx's actual argument in *Capital*. More specifically, some authors have objected to the commodity nature of labour power (hence to the very idea of there being a 'value' of labour power).[81]

---

[79] It is this determination that generates the appearance that the class struggle as such embodies the potentiality to transcend the capitalist mode of production.

[80] For a fuller discussion of the issues treated in this Appendix, see Caligaris and Starosta 2015; Fitzsimons and Starosta 2015.

[81] The rejection of the commodity nature of labour power, and *a fortiori* of Marx's account of the determination of its value, has come from rather disparate traditions, namely, the

In the second place, and more intimately connected with the theme of this chapter, many (if not most) Marxists tend to claim that the value of labour power is (at least partially) *determined* by the class struggle. In light of the centrality of this latter issue for the content of this book, it is worth giving it closer scrutiny.

Class Struggle and the Determination of the Value of Labour Power: The 'Received Wisdom' and Its Limits

As mentioned above, most if not all Marxists tend to take for granted that the class struggle determines, at least in part, the 'standard of necessity' or 'customary living standard' implied in the reproduction of the class of wage workers. There are, however, variations within this theme.

At one end of the spectrum, there are those scholars who conceive of the class struggle as the fundamental (if not the only) *determinant* of the value of labour power. For instance, this is the case of authors belonging to the so-called 'New Solution' perspective.[82] As Mavroudeas perceptively notes,[83] the implication of the 'New Solution' approach is that the value of labour power must be considered, in a rather Smithian fashion, as the quantity of 'labour commanded' by the money wage, which in turn is solely determined by the class struggle in the sphere of *distribution* (or maybe mediated through specific 'institutional arrangements'). The 'Autonomist' theory of the *political* determination of the wage can also be seen as sharing in this broad perspective, albeit with a more 'orthodox' focus on the class struggle in *production* (thus preserving the link between socially necessary labour time actually expended in the production of 'wage goods' and the value of labour power, which is lost in the 'New Solution' approach).[84] Despite their differences, however, for both perspectives the determination of the value of labour power ultimately comes down to a simple expression of *power relations* between social classes. There are two problems with this. Firstly, the objective social basis of the respective power of each social class is left without explanation. More importantly, since thus conceived the value of labour power bears no relation to the conditions

---

systematic dialectics strand of value form theory (Arthur 2006, pp. 90–3; Reuten 1988, p. 56; Reuten and Williams 1989, pp. 68–9) and the so-called New Solution to the 'transformation problem' (Lipietz 1985, p. 154; Mohun 1994b, pp. 397–8, 400–1; Foley 1982, pp. 42–3). For a critique of the New Solution's departure from Marx's argument about the commodity nature of labour power, see Mavroudeas 2001.

[82] For references, see previous footnote.

[83] Mavroudeas 2001, p. 55.

[84] Negri 1991, pp. 132–3; Cleaver 1979, pp. 80–5.

in which labour power is expended in the direct process of production, all connection is lost between the reproduction of the capital relation and the *materiality* of the human metabolic process in its unity (i.e. the nexus between social production and consumption).

However, the majority of Marxist scholars tend to support a rather different approach to the determination of the value of labour power. This widespread view hinges on the distinction made by Marx in Chapter 6 of *Capital* between the 'physical' element of the value of labour power ('natural needs, such as food, clothing, fuel and housing') and the 'historical and moral' component ('which depend therefore to a great extent on the level of civilisation attained by a country' and 'on the conditions in which, and consequently on the habits and expectations with which, the class of free workers has been formed').[85] Insofar as the former element is usually seen as directly linked to the recovery from the prior expenditure of labour power in the direct production process, the materiality of the reproduction of the wage labourer is taken into consideration by this approach. However, these authors add to what they consider to be the strictly material element of the value of labour power a historical and social element constituted by the 'customary standard of living', which in turn is seen as determined by the class struggle.[86] It is this latter component which, allegedly, sets Marx's approach apart from Ricardo's 'beast of burden' view of the determination of the 'value of labour'. Whilst this perspective on the value of labour power is more rigorous and consistent with the Marxian critique of political economy, it is not itself exempt from shortcomings.

The first thing to note in this regard is that despite its widespread acceptance among Marxists, the idea of the *determination* of the value of labour power by the class struggle has no supporting textual evidence from Marx's writings. There is no single passage in *Capital* (or in other works for that matter) in which he states that the 'average' amount and qualitative nature of means of subsistence results from the balance of class forces. More specifically, at no point does Marx state that, in contrast to the physical element of the value of labour power, the historical and moral element is constituted by the class struggle. What he does say is that that the latter component expresses the specific conditions inherited from *pre-capitalist* social relations underlying the genesis of each national fragment of the global working class, i.e. the 'general level of civilisation' attained in a particular place at a particular time. In Marx's own words, 'the important part' in the determination of those social conditions is not played by the class struggle but, as he puts it in *Value, Price and Profit*, by 'historical tradition and social habitude'.[87]

---

[85] Marx 1976g, p. 275. This, I think, is the general determination underlying E.P. Thompson's historical study of the 'moral economy'. See Thompson 1971.

[86] The references for this perspective are numerous since it constitutes the general consensus among Marxists. See Mavroudeas (2001, pp. 58–9), Lapides (1998, p. 177), and Lebowitz (2003, p. 74), for paradigmatic exponents who discuss the matter explicitly and at great length. Still, the same ideas are touched upon in passing by many other authors. See, for instance, Bellofiore (2009b, pp. 194–7) and Heinrich (2012, p. 94).

Incidentally, it is *Value, Price and Profit* from which some scholars draw the textual evidence for the idea of the class struggle as determining the value of labour power.[88] However, in those passages Marx only states that the fixation of the actual degree of *profit* among the immense scale of possible variations up to its maximum is settled by the continuous struggle between capital and labour.[89] This maximum corresponds to the 'physical minimum of wages and the physical maximum of the working day'. In other words, it corresponds only to the 'physical component' of the value of labour power. Thus, what Marx discusses in that text is the extent to which the class struggle manages to make the actual level of the *wage* approximate the full value of labour power, which includes the 'traditional standard of life' above the physical minimum.

As far as *Capital* is concerned, the situation of a price of labour power falling below the traditional standard of life to its 'minimum' is characterised by Marx as involving the purchase of labour power below its value.[90] But he does not state that the 'traditional standard of life' (and *a fortiori* the full value of labour power) itself varies according to the ebbs and flows of the class struggle.[91] Exegetical issues aside, we shall see in the next section that, even at a substantive level, matters are much more complex than they appear at first sight.

[87] Marx 1985, p. 145.

[88] See, for example, Lapides 1998, p. 177.

[89] Marx 1985, p. 146.

[90] Marx 1976g, p. 277.

[91] In one of the few remarkable exceptions (if not the only one) to the 'received wisdom', David Harvey makes a similar point in *Limits to Capital* (2006, pp. 54–6). However, the question is one-sidedly reduced (in a rather 'Luxemburgist' or underconsumptionist fashion) to the essentially *quantitative* problem of the realisation of surplus value.

Rethinking Marx's Account of the Determinations of the Value of Labour Power

The main thrust of Marx's argument about the determination of the quantity and quality of the bundle of commodities that constitutes the value of labour power is that it is resolved into what is 'needed to maintain it, i.e. to maintain the worker's life as worker, so that having worked today he will be able to repeat the same process under the same conditions the next day'.[92] As Marx puts it in Chapter 6 of Volume I of *Capital*, 'the means of subsistence must therefore be sufficient to maintain him in his *normal state* as a *working individual*'.[93] Several key issues follow from this.

In the first place, this implies that it is the consumption of those means of subsistence that (re)produces 'the muscles, nerves, bones and brains of existing workers',[94] and whose materiality bears 'the aggregate of those mental and physical capabilities which he sets into motion whenever he produces a use-value of any kind'.[95] In other words, it is through the appropriation of those use values that the worker (re)produces the *materiality* of her/his *productive subjectivity* which, as argued at great length in the first part of the book, is nothing more (but also nothing less) than her/his human individuality or species-being. Consumptive activity therefore reproduces the materiality of the specifically human attributes of the individual: her/his productive consciousness and will, i.e. 'what distinguishes the worst architect from the best of bees'.[96] The other side of the same coin, however, is that the 'amount and quality of the means of subsistence, and therefore also the extent of needs'[97] that enter into the wage worker's consumption bundle, can have no material determination other than that which is necessary to reproduce whichever specific form the productive 'ability, aptitude and power enclosed in the living body of the worker' takes at a 'certain level of civilisation'.

Furthermore, this raises the question as to what exactly Marx means by the '*normal* state as a working individual'. A first self-evident but trivial answer is that the wage labourer must be able to act in the particular labour process in which she/he usually takes part. However, a passage quoted above from the *1861–3 Manuscripts* is a little more specific: she/he has to be able to repeat her/his participation in the labour process *in the same conditions* as the previous day. The question therefore turns to what is entailed by those conditions. In many passages Marx gives the impression that he has in mind only the *physical* reconstitution of the wage worker as implicated in the normal state of her/his labour power. Thus, in Chapter 6 of *Capital*, he explicitly refers to those same conditions in relation to health and strength.[98] At some point in the *1861–3 Manuscripts*, he adds 'vitality in general' to the list.[99] These formulations can lend themselves to the association of the normal state of labour power solely with the so-called 'physical' component of the value of labour power.[100] However, two arguments militate against this reading.

---

[92] Marx 1988, p. 42.

[96] Marx 1976g, p. 284.

[97] Marx 1988, p. 42.

Firstly, in those preparatory manuscripts, just a few lines below, Marx introduces a clarifying remark stating that 'it is hardly necessary to mention here that the head belongs to the body as well as the hand'.[101] I take it to mean that the normal state as a working individual involves not only fully functioning physical capabilities, but also the '*mental*' capabilities whose 'aggregate' constitute labour power in its unity, according to Marx's own definition. This is, to some extent, self-evident, insofar as the particular concrete labour performed by some wage workers might involve mainly intellectual activity (e.g. academic labour). Both Marx's stress on the physical 'wear and tear' of labour power, and his clarification that 'mental' capabilities must not be forgotten, might have to do with the fact that in his time the great majority of workers performed mainly 'manual' labour in the direct production process and intellectual wage labour was scarcely developed. However, I shall argue below that much more is involved in the normal reproduction of those 'mental capabilities' than what Marx insinuates. Secondly, I showed above that in *Capital* Marx is unambiguous that the reduction of the price of labour power to a magnitude which only covers the ultimate minimum given by the *physically* indispensable means of subsistence, involves its fall below its value. As I see it, the upshot of this is that for Marx it is the overall 'customary standard of life', which *includes* the 'historical and moral' component, that constitutes the wage labourer's 'normal state as a working individual'.

This latter point dovetails with another key issue worthy of discussion following from Marx's simplest definition of the value of labour power. It also relates to the aforementioned broader significance of the 'mental capabilities' that comprise labour power. For the productive attributes of workers (and so

---

[98] Marx 1976g, p. 275.

[101] Marx 1988, p. 51.

their productive subjectivity) do not just include those that are strictly necessary for the labour process in a restricted 'technical' sense (the specific knowledge required for the performance of the determinate productive tasks under their individual responsibility). Additionally, they comprise what, in keeping with Marx's terminology of the historical and moral component of the value of labour power, can be referred to as 'moral attributes' as well. By this I mean the 'aggregate' of determinate forms of consciousness, self-understanding, attitudes and dispositions that *also* need to be 'set into motion whenever the workers produce a use value of any kind'. These moral attributes are of course not natural but the product of history, and therefore vary with the 'level of civilisation' attained by society, i.e. with the historically specific technical configuration of the production process that constitutes the general material basis in each phase of capitalist development. Moreover, they differ for each partial organ of the collective labourer in accordance with the differences in the productive functions that each of them respectively undertakes under the command of capital. Crucially, primordial and generic among those 'moral' attributes (hence cutting across every segment of the working class) is what I have presented (in Chapter 6) as the most general form of subjectivity taken by the alienated consciousness of the private individual in the capitalist mode of production, namely, the personal freedom and independence of the commodity producer.[102] As we have seen, this freedom as a concrete form of the alienation in the commodity form is not simply an abstractly ideological, juridical or cultural form. It is first and foremost a *material* determination of the productive subjectivity of the human individual, a *productive power or attribute*.[103]

With all these elements in mind, I would like to suggest a possible interpretation (or resignification) of what Marx might have been getting at with the distinction between the 'physical' and the 'historical and moral' component of the value of labour power. Succinctly put, the former broadly corresponds to the (re)production of the strictly 'technical' dimension of labour power as defined above. Here I am quite simply sticking to the letter of Marx's text (with the proviso that, as he further clarifies, the costs of education and training deriving from the degree of complexity of labour power must be added to this 'technical' component). As a consequence, the point is rather uncontroversial and there are few disagreements among commentators. The key contentious issue hinges on the 'historical and moral' element which, as we have seen, without any solid textual evidence most Marxists take for granted as condensing the result of the class struggle. By contrast, my argument is that this other component of the standard of life of workers condenses the *materially determined* aggregate of use values which are qualitatively and quantitatively necessary to (re)produce her/his productive attributes as a personally free working subject who, through this freedom, affirms her/his objective subjection to the autonomised movement of the product of her/his social labour (capital). Thus, *both* the 'technical' attributes of labour power and the different dimensions of the general 'moral' attribute as a personally free subject are *productive requirements* for the reproduction of capital. In this sense, *both* are *fully determined* by the *material* conditions of the valorisation of capital in the production process.[104]

---

[102] In reality, all those other dimensions of the 'moral' productive attributes of wage workers are diverse *specifications* of their free consciousness as the *generic* determination of their subjectivity of private working individuals. In *The Results of Immediate Process of Production*, Marx discusses in great depth the determination of 'the idea of self-determining freedom' as a productive attribute. See Marx 1976c, pp. 1026–34.

[103] This actually applies to all moral attributes described above. So-called 'cultural' forms, 'values' and 'identities' are not abstractly autonomous entities floating in mid-air, but concrete forms of existence of the production and reproduction of the materiality of human productive subjectivity.

At this juncture, a final question obviously arises. For in this account of the determinations of the value of labour power, and contrary to the 'received wisdom' of Marxists, the class struggle seems to play absolutely no part. It could seem that in order to access the means of subsistence that they need for the normal reproduction of their labour power, workers can safely leave the establishment of its value to the 'automatic' operation of the 'iron law of wages'. Unlike the establishment of a normal working day discussed above, here there would be no need to 'put their heads together as a class' in order to obtain in circulation the full value of their labour power. In the concluding section of this Appendix, I show why this is not the case.

---

[104] Although not free from ambiguities, the conceptualisation of the nexus between working-class consumption and their reproduction as bearers of the capital-relation can be traced back to Aglietta's *A Theory of Capitalist Regulation* (2000). In that book, Aglietta explicitly states that the workers' consumption is a process that is subject to a 'general logic' of reconstitution of the forces expended in social practices and of preservation of capacities and attitudes entailed by the social relations of which individuals are carriers (2000, p. 156). What is more, among those 'capacities and attitudes' Aglietta includes those processes that maintain 'social relations of an ideological nature', making clear that those other relations 'posses just as "material" an existence as economic relations' (2000, p. 157). However, presumably under the influence of the then fashionable Althusserian structuralism, Aglietta further argues that those processes 'are not directly under the sway of the relations of production' (ibid.). In this way, he ends up losing sight of the inner material connection between the process of capitalist production and the 'norm of consumption' in its totality. As noted by Mavroudeas (2003), this severance of the link between capitalist production and working-class consumption is even more pronounced in Aglietta's concrete empirical analysis of the evolution of capital accumulation in the United States. Thus, the 'Fordist' norm of consumption is not seen as expressing the reproduction of wage-workers with novel productive attributes (both physical and moral), as demanded by the new material forms of the labour process. Instead, the change in the norm of consumption is, in underconsumptionist fashion, attributed to the need to resolve the disequilibrium between sector I (that produces means of production) and sector II (that produces means of subsistence), in the context of an 'intensive regime of accumulation'.

Content and Form of the Determination of the Value of Labour Power: On the Role of the Class Struggle

In contrast to the view outlined above, Marxists tend to conceive of the inner connection between the conditions of reproduction of labour power and the material forms of its consumption in the capitalist production process as solely pertaining to the 'physical/technical' component of the workers' consumption. Regarding this part of the workers' standard of necessity, they would not deny that it is *determined* by the material conditions of the direct production process of capital. However, all the means of subsistence which do not appear as immediately linked to the physical and technical reconstitution of labour power are seen as having no intrinsic connection whatsoever with the materiality of the capitalist labour process. The 'historical and moral' element is therefore rendered as *materially indeterminate* and subject to the *contingent* result of the struggle between capitalists and workers, who are therefore not seen as personifications of antagonistic necessities of the reproduction of their alienated social being in its unity (i.e. the total social capital), but as abstractly free political subjects pursuing the satisfaction of their class interests and needs.

The approach developed here leads to another view of the connection between the determination of the value of labour power and the class struggle. True to the methodological perspective informing this book, the key to this nexus hinges on the 'unity-in-difference' between the content and the form of the determination at stake; or, to put it differently, between the determination proper and its necessary mode of motion or realisation. Specifically, the material conditions of the reproduction process of capital (i.e. the unity between social production and consumption) constitute the *content* of the determination of the value of labour power. They do so by materially determining the differentiated forms of productive subjectivity that compose the collective labourer and, as a consequence, the quantity and kind of means of subsistence that workers need to consume to produce and reproduce those diverse qualitative attributes (both technical and moral) of labour power. In turn, the class struggle becomes the necessary *form* that *mediates* the establishment of the material unity between the productive and consumptive requirements of the reproduction of the total social capital. Note, however, that the necessary mediating role of the class struggle in concretely *fixing* (as opposed to *determining*) the customary living standard of workers does not only apply to the historical and moral component; it also pertains to the workers' consumption bundle *as a whole*, i.e. including the physical or technical element. In other words, there is not a single use value entering the determination of the value of labour power, whose consumption is not *secured through* the struggle of wage workers as a class. Conversely, the other side of the same coin is that there is not a single use value consumed by wage workers which is not *determined by* the material requirements of the valorisation process of the total social capital (which, it goes without saying, might clash with the immediate interest of individual capitals).

From a textual point of view, this perspective is consistent with the only evidence on this issue that Marx left us in his works. On the one hand, I have briefly mentioned above his comments from *Value, Price and Profit*, the only text in which he *explicitly* discusses the connection between the class struggle and the quantitative and qualitative determination of the 'norm of consumption' of the working class. On the other hand, the close textual reconstruction of Chapter 10 of *Capital* on the 'Working Day' offered earlier in this chapter tends to support and confirm this reading. According to Marx's account in those pages, class antagonism is not the self-determining process that contingently establishes the duration of the working day. By contrast, it is the *mediating social form* that forces the capitalist state to set legal limits to its extension beyond its *normal* length. However, the *content* of this normality is not undetermined, although it *appears* as such at first sight at the beginning of the presentation in the respective chapter. But as the exposition unfolds, it emerges that the normal duration of the working day is *materially determined by* the conditions in which labour power is consumed by capital in the process of production.[105] A normal working day is therefore that which does not lead to the premature exhaustion of labour power. The class struggle over the length of the working day thus gives shape to the payment of labour power at its full value. It is the same with the amount and quality of means of consumption that enter into the reproduction of working class.

---

[105] Since at the systematic expositional stage of Chapter 10, the material forms of the labour process are an external presupposition vis-à-vis the self-movement of capital, Marx does not need to say much about the specific determinations that generate the necessity for the shortening of the working day beyond a general reference to overwork and premature exhaustion of labour power caused by capital's 'voracious appetite for surplus labour'. However, as the systematic exposition progresses to the real subsumption of labour to capital, the material foundation of that alienated social necessity is brought to light: the shortening of the working day is the necessary concrete form taken by the increase of the *intensity* of labour that large-scale industry brings about. See Marx 1976g, p. 536.

Substantively, all this is a necessary corollary of the constitution of the total social capital as the alienated subject of the human reproduction process in its unity. As much as the determinations of the direct production process, the process of individual consumption becomes inverted into an attribute of capital. The development of human labour power is not the end of capitalist production, but simply a means for the only finality presiding over its movement: the production of surplus value. To claim that the material content of social consumption does not (fully) derive from the requirements of the reproduction of capital renders that moment of the human metabolic process as external to the alienated social forms in which the latter exists. In other words, it involves an unmediated grounding of workers' needs in an anthropological determination of the human species. *A fortiori*, working class struggles over the conditions of their material reproduction become represented as a political assertion 'of the needs of workers as *human beings* in opposition to the rights of capital as property'.[106] We have seen, however, that when workers struggle as a class, they do not unmediatedly act in their abstract determination as persons (i.e. as human beings), but as *personifications* of the only commodity they own and, in that condition, as executors of the establishment of the material unity of the total social capital. Through their apparently free struggle for their personal needs, they therefore satisfy an alienated 'need' of the total social capital. The theoretico-political challenge for the critique of political economy is to discover the form determination that *immanently* carries the objective potentiality for their conscious self-abolition as such personifications. The determination of the value of labour power is no such form.

---

[106] Lebowitz 2003, p. 99. Indeed, for Lebowitz, the ground of the tendency to drive beyond wage labour is the abstract humanity of the worker: 'Ultimately, then, both for the Young Marx and the mature Marx (the "scientist"), it is because workers are not *merely* wage-labourers but are human beings that there is a tendency to drive beyond wage-labour. Underlying the struggle against capital is that the worker "strives not to remain something he has become, but is in the absolute movement of his becoming" (Marx, 1973: 488). *In the end, we understand the contradiction of capital and wage-labour as that of wage-labour and the human being'* (Lebowitz 2003, p. 207).

CHAPTER 8

Real Subsumption and the Genesis of the Revolutionary Subject

Introduction

Thus far, my critical reconstruction of Marx's argument in *Capital* has focused on determinations which belong to what Marx termed the *formal* subsumption of labour to capital, i.e. to the concrete form of production of surplus value in which the materiality of the production process remains a given presupposition of the valorisation process. As we have seen, nothing in those determinations places us before the central question I have been trying to answer through this reading of Marx's texts, namely, the necessity of revolutionary subjectivity. From a merely textual point of view and, as it were, 'by default', this already offers a clue as to the alternative place in which to search for those social determinations: the *real* subsumption of labour to capital. In effect, I shall argue in this chapter that it is precisely in the development of the ever-changing concrete forms of the real subsumption that the answer to the question about revolutionary subjectivity is to be found.[1]

---

[1] A methodological question that immediately arises concerns the role of the different concrete forms of the real subsumption in Marx's 'systematic-dialectical' exposition in *Capital*. On the one hand, Tony Smith argues that simple co-operation – which, incidentally, he incorrectly sees as expressing the formal subsumption of labour to capital – 'does not characterize a specific stage in the reconstruction in thought of the value-form' (1990a, p. 126). On the other hand, he does admit that capital's necessity to transform the materiality of the production process of human life must have a place in the 'systematic ordering of the categories'. But this transformative dynamic, captured by the category 'capital as principle of transformation', must remain at that level of generality, the specific concrete forms of the production of relative surplus value having no necessity other than being arbitrary 'historical examples' among 'a myriad of combined and uneven forms that could have been selected' (Smith 1990a, p. 127). Murray, for his part, correctly points out against Sayer (1987) and Balibar (1968) that all three material forms of the labour process belong to the real subsumption of labour to capital. However, he considers that only the general concept of co-operation belongs to the systematic dialectical argument, the three concrete forms of co-operation belonging to a separable historical dialectics (Murray 2004, pp. 251, 258). Finally, Reuten and Williams (1989) simply exclude the concrete forms of production of relative surplus value from their systematic presentation of the determinations of the 'bourgeois epoch'. In my view, a rigorous

© KONINKLIJKE BRILL NV, LEIDEN, 2016 DOI: 10.1163/9789004306608_010

The proposition that the real subsumption constitutes the ground of revolutionary subjectivity should come as no surprise. In reality, this is no more than the concretisation of that insight about the most general determination of the process of 'natural history' constituting the development of humanity that Marx expounded in the *Paris Manuscripts* in 1844. According to that early text, the content of the history of the human species consists in the development of the specific material powers of the human being as a working subject, that is, of *human productive subjectivity*. It is in the historical transformation of its material and social forms, Marx concluded, that the key to the abolition of capital – hence, to revolutionary subjectivity – should reside. However, I have argued in the first part of this book that this early attempt at the critique of political economy could not offer a rigorous scientific comprehension of the social determinations underlying the revolutionary transformation of society.

It was fundamentally in *Capital* (but, crucially, also in the *Grundrisse*), mainly through the exposition of the determinations of the different forms of production of relative surplus value (hence of the real subsumption of labour to capital), where Marx managed to concretise the systematic dialectic of alienated human labour which he had grasped only abstractly in his early writings. He did this by showing precisely what the capital form does to the materiality of human productive subjectivity as it takes possession of, and transforms, the labour process. Seen externally, the implicit concrete question under investigation was the following: does capital transform human productive subjectivity in a way that eventually equips the latter with the material powers to transcend its

---

treatment of the qualitatively different concrete forms of the real subsumption must be an essential moment of the systematic-dialectical presentation of the determinations of capital. The chapters of Marx's *Capital* dealing with the forms of production of relative surplus value are not there simply for the sake of an arbitrary historical illustration. Rather, as I demonstrate below, they are part and parcel of the dialectical unfolding of the immanent dynamic of self-valorising value, and the transition between them expresses the necessary forms of development of human productive subjectivity as an alienated attribute of capital. Their exclusion from the presentation can only result in a formalistic comprehension of the nature of capital, which posits as contingent the relation between the latter and historical transformations of the materiality of the production process of human life. On the other hand, it should be noted that neither the distinction between formal and real subsumption, nor the one among the different forms of the latter, express pure historical phases of capitalist development on the basis of which to construct a formalistic periodisation. The historical material in those chapters should be read in exactly the same way as that of the chapter on the working day, that is, as a 'historical sketch' which, in its 'empirical' existence, expresses the realisation of the more abstract determination.

alienated social form of development? From this materialist standpoint, only if this were the case would it make sense to pose the question of conscious revolutionary action as a concrete objective potentiality immanent in capitalist society. As Marx puts it in an oft-quoted passage from the *Grundrisse*,

> On the other hand, if we did not find concealed in society as it is the material conditions of production and the corresponding relations of exchange prerequisite for a classless society, then all attempts to explode it would be quixotic.[2]

In other words, Marx's point was the need to discover the material determinations of communist society in their present mode of existence as an *alienated potentiality* engendered by the autonomised movement of the capital form to be realised – that is, turned into *actuality* – precisely and necessarily through the conscious revolutionary action of the self-abolishing proletariat.[3]

Those determinations appear scattered and are just mentioned in passing in several of Marx's texts. They all characterise the simplest defining character of communism as the fully self-conscious organisation of social labour as a collective potency by the thereby freely associated producers. It is in the *Grundrisse*, in the context of the critique of Adam Smith's conception of labour as sacrifice, that Marx offers the clearest and most concise characterisation of the general attributes of what he calls 'really free working'.

> The work of material production can achieve this character [i.e. as 'really free working'] only (1) when its social character is posited, (2) when it is of a scientific and at the same time general character, not merely human exertion as a specifically harnessed natural force, but exertion as subject, which appears in the production process not in a merely natural, spontaneous form, but as an activity regulating all the forces of nature.[4]

---

[2] Marx 1993, p. 159.

[3] Note that as a consistent materialist, Marx tended vigorously to reject the formulation of 'recipes (Comtist ones?) for the cook-shops of the future' (Marx 1976g, p. 99). In other words, he refused time and again to elaborate on the *actual concrete forms* that social life would take under the free association of individuals or communism. However, this did not prevent him from grasping the *most general or simplest* determinations of the social form that constitutes the determinate negation of the capitalist mode of production in the only way available to an individual living before the emergence of the material conditions for the abolition of capital, i.e. as an objective potentiality.

[4] Marx 1993, pp. 611–12. This crucial passage has not generally caught the attention of Marxists.

The interesting and 'intriguing' aspect of this passage is that Marx claims not only that in order to be really free labour must become a consciously organised, directly social activity, but also that the consciousness regulating that emancipated productive activity must be of a *general* and *scientific* kind.[5] As we shall see later, this latter attribute, scarcely mentioned by Marx on other occasions,[6] will prove to be of paramount importance for the comprehension of the concrete determinations of revolutionary subjectivity; a task that Marx himself achieved, although not without tensions and ambiguities. At this stage, I would just like to reformulate the question of the relation between capital and productive subjectivity posed above in light of that passage from the *Grundrisse*. Does the development of capital transform human productive subjectivity in such a way as to engender the necessity of producing the latter with the two general attributes mentioned by Marx? Furthermore, is the working class the material subject bearing them?

I think that the answer to these questions lies at the basis of any attempt to develop a materialist account of the determinations of revolutionary subjectivity. It is a question not just of the mere will to radically 'change the world', but of the concrete *material powers* to do so. In this final chapter, then, I discuss the way in which Marx, through the dialectical exposition of the contradictory movement of the real subsumption, actually presented the genesis of the revolutionary subject, thereby determining the critique of political economy as the proletariat's self-consciousness of the *alienated* social necessity of its political action.

An exception can be found in Schmidt (1971, pp. 143–4), who offers an interesting discussion of the determinations of emancipated labour.

[5] The Nicolaus translation of that passage of *Grundrisse* is not uncontroversial. The 'general' character of labour that is really free is Nicolaus's English choice of word for 'allgemeine Arbeit'. However, a passage of Volume III of *Capital* in which Marx also refers to scientific labour as 'allgemeine Arbeit' (Marx 1991, p. 199) is translated by Fernbach as 'universal labour'. This latter translation seems preferable in light of the argument developed in this chapter. Besides, it is to be noted that 'das Allgemeine' is the term that Hegel uses in his *Logic* to refer to 'the universal'. See Inwood 1992, pp. 302–3.

[6] See, however, Marx's remarks in the *Paris Manuscripts* on the need for the constitution of 'natural science of man' or 'human natural science' as the basis for emancipated human practice (Marx 1992, p. 355).

The Production of Relative Surplus Value: General Determinations

With the determinations unfolded so far in this reconstruction of *Capital*, i.e. with the material conditions of production and the value of labour power taken as a given presupposition, the valorisation of capital can only expand through the increase in the amount of labour that it sets into motion. This, in turn, can only be achieved by the lengthening of the working day and/or by the increment of the number of workers exploited. I have already mentioned how the physical and social limits to the duration of the working day are asserted in the concrete form of the class struggle.[7] The extension of number of wage workers option has its 'mathematical limits' determined by the growth of the working population.[8] These barriers to the production of surplus value are transcended by capital by giving its valorisation the concrete form of the production of relative surplus value.

The revolution in the material conditions of the social process of production, and the consequent *real subsumption* of labour under the rule of capital, constitutes the general determination of the production of relative surplus value. In its different forms, the production of relative surplus value consists in the transformation of the materiality of the labour process (and, crucially for my argument, *in the subjectivity of the wage labourers*) in order to raise the productivity of labour and, therefore, reduce the value of labour power and increase the rate of surplus value. In this way, capital internalises the determination of that which, up to this stage, existed as an external condition for its power of self-valorisation, namely, the magnitude of variable capital. Notice that I am not referring here just to an abstract increase in the productivity of social labour unilaterally taken in its quantitative determination, i.e. as the development of the capacity to produce more use values with the same amount of labour. As we shall immediately see, the key to this development lies in its specific *qualitative* aspect (which obviously entails a quantitative determination as well), consisting in the advance of the productive co-operation of the labourers through simple co-operation, the division of labour of manufacture and the automatic system of machinery of large-scale industry.

---

[7] Besides, the extension of the working day would reach its absolute limit at the point of determining the whole 24 hours of the day as a means of producing surplus value. See Marx 1976g, p. 419.

[8] Marx 1976g, p. 442.

Co-operation and Capital's *raison d'être* in the Historical Process

In simple co-operation, the free wage labourer must apply her/his consciousness and will to the realisation of her/his individual productive activity which, as with the independent artisan, still involves the production of the commodity in its entirety. However, insofar as she/he is *doubly* free, she/he must do so in the conditions imposed by the direct relation established with the capitalist (to whom she/he freely sold her/his labour power) within the immediate process of production. On the other hand, the capitalist is able to transform her/his money into capital because she/he employs not just one wage labourer, but a relatively large number of them. Thus, the possession by the capitalist of a certain magnitude of capital becomes a material condition for the realisation of this social production process.[9]

The labour of these numerous workers working 'together side by side in accordance with a plan, whether in the same process, or in different but connected processes' takes the form of *co-operation*.[10] *Simple* co-operation, the mere agglomeration of the individual wage labourers under the same roof, produces a first transformation in their labour process by determining them as members of a collective productive organism, a collective labourer.[11] The initial *formal* expression of this is the objective constitution of the expenditure of the labour power of the co-operating labourers as *average social labour*.[12] However, beyond this formal aspect and the aforementioned constitution of a collective labourer, the materiality of the individual human productive subjectivity of the workers qualitatively remains the same as in pre-capitalist forms of handicraft labour. As Marx puts it, these developments in the process of production of human life derived from simple co-operation do not entail any major 'alteration in the method of work' itself.[13]

And yet, a *material* revolution in the conditions of the labour process does take place: simple co-operation gives the free wage labourers' labour process a *directly social character*. In the first instance, Marx notes, this mainly affects the objective conditions of the production process, which start to be consumed in common, thereby resulting in the economy in the use of means of production.[14]

---

[9] Marx 1976g, p. 448.

[10] Marx 1976g, p. 443.

[11] As Marx points out, co-operation is the 'fundamental form of the capitalist mode of production', whereas simple co-operation is its most abstract form (Marx 1976g, p. 454).

[12] Marx 1976g, pp. 440–1.

[13] Marx 1976g, pp. 441.

[14] Marx 1976g, pp. 441–2.

But, in addition, the directly social character of the labour process reacts on the subjective factor as well. Although the productive subjectivity of each worker remains unaltered, the productive powers of human labour do suffer a development. First, the human individual being a social animal, through this co-operation the productive powers of social labour are enhanced so that the worker 'strips off the fetters of his individuality, and develops the capabilities of his species'.[15] Secondly, not only do the workers develop their individual productive powers, but also a directly social potency is created, 'a new productive power, which is intrinsically a collective one'.[16]

The significance of all this cannot be overestimated. For even these simplest determinations of the real subsumption suffice to put us, for the first time in this reconstruction of Marx's dialectical exposition, before an all-important aspect of the critique of political economy. I am referring to the discovery of the *material specificity* of capital. In effect, one of the central questions addressed by Marx's presentation in Chapter 13 of *Capital* is to show that, as a social form, capital not only entails a formal specificity – the inversion of human powers as powers of the product of labour – but also a material one. Or rather, it involves a specific material determination that can only develop through a specific social form. More concretely, *capital is the social form that transforms the productive powers of free but isolated individual labour into powers of directly and consciously organised social labour*.[17]

As Marx points out, co-operation in the production process can be found in earlier social forms of the reproduction of human life. However, those forms presuppose a very weak development of the individuality of the human producer, either because they are based on the common ownership of the conditions of production and on an individual who 'has as little torn himself free from the umbilical cord of his tribe or community as a bee has from his hive', or, alternatively, because they 'rest on direct relations of domination and servitude, in most cases on slavery'.[18] Capitalist co-operation, on the contrary, presupposes a degree of development of the productive individuality of the labourer historically 'attaining classical form' in the form of the *freedom and independence* of the *isolated* individual labour of the peasant and the artisan, i.e. on the basis of the *dissolution* of all relations of personal dependence.[19] As Marx puts it when summarising at the end of Volume I the essence of the historical tendency of capital accumulation,

---

[15] Marx 1976g, p. 447.

[16] Marx 1976g, p. 443.

[17] Strictly speaking, Marx's exposition encounters a first manifestation of this immanent self-negation of the productive powers of private labour when discovering the doubling of the commodity producer into capitalist and wage labourer. As we have seen, already in Chapter 7 Marx shows how the capitalist acts as the productive consciousness of the unity of the worker's activity in the direct process of production. In other words, already at that stage the dialectical presentation reveals that private labour as the general social relation actually involves a situation in which a personally free individual directly organises the labour of another personally free human being within each private fragment of social labour.

> [t]he private property of the labourer in his means of production is the foundation of petty industry, whether agricultural, manufacturing, or both; petty industry, again, is an essential condition for the development of social production and of the free individuality of the labourer himself …[20]

At this juncture it is necessary to emphasise that the mode of existence of social labour as private labour is not simply a juridical form referring to the fragmentation of the property of means of production (though that is certainly its *simplest* juridical expression).[21] But neither should it be understood as an abstract atomisation of social production unilaterally seen from an exclusively formal point of view, i.e. as just another social form of the production process of humanity that constitutes the present-day objective conditions in which human individuals exercise their naturally free productive consciousness. As a social form, the private character of labour must be understood in its essential determination as a mode of development of the material productive forces of society borne by individual labour, i.e. of human productive subjectivity. Hence the simplest form determination of private and independent labours discussed in Chapter 5: the absolute *material* capacity consciously to rule the individual character of labour, with no control of its general social character. In other words, private labour as a social form must be comprehended in relation to the *individually borne material powers of human beings* consciously to organise their socially determined transformative action upon the natural environment, i.e. the productive consciousness of human beings as working subjects.

---

[18] Marx 1976g, p. 452.

[19] Marx 1993, p. 156. That is why Marx centres the great bulk of his exposition of primitive accumulation and of the historical tendency of capitalist accumulation in the (violent) expropriation of the independent agricultural producer, which 'forms the basis of the whole process' (Marx 1976g, p. 876), instead of elaborating on the 'direct transformation of slaves and serfs into wage-labourers', which is a 'mere change of form' in the exploitation of the direct producers (Marx 1976g, p. 927). It is the former transition that condenses the essential material content of the social transformation at stake, i.e. the specific historical powers of the capital form in the development of human productive subjectivity. This point is completely overlooked by those formalistic approaches that reduce the capital form to a relation of power and struggle. Thus, to Holloway, the essence of the genesis of the capitalist mode of production is best captured as the process of conversion of the serf into a wage labourer (Holloway 2002b, pp. 180–3), i.e. as the 'mere change of form' of exploitation of the direct producers. The *raison d'être* of capital in the materiality of human (pre)history is simply left out of the picture.

[20] Marx 1976g, p. 927.

[21] As Chattopadhyay (1996) notes, in the classic works of Soviet Marxism (including Lenin, Trotsky, Bukharin and Preobrazhensky) there was a noticeable tendency to conceive of the social relations of production as primarily *juridical*. The 'juridicist' ideological representation can also be found in Kautsky (1978).

It follows from this that if human beings invert their social powers as the value form of the product of labour, it is because they have developed the individual character of their productive powers to a degree that cannot be further expanded under relations of personal dependence. However, the other side of this coin is that they have not yet created the universality of the material powers needed to regulate their social reproduction in a fully conscious form either. This is why the product of their social labour still confronts them as an alien power in the form of capital and the material development of their productive subjectivity takes the form of the production of relative surplus value.

> But it is an insipid notion to conceive of this merely *objective bond* as a spontaneous, natural attribute inherent in individuals and inseparable from their nature (in antithesis to their conscious knowing and willing). This bond is their product. It is a historic product. It belongs to a specific phase of their development. The alien and independent character in which it presently exists *vis-à-vis* individuals proves only that the latter are still engaged in the creation of the conditions of their social life, and that they have not yet begun, on the basis of these conditions, to live it.[22]

It is the socialisation of that historical form of free labour – necessarily realised through the alienated value form of the product of labour and through the relative mutilation of that individuality imposed by the second sense of the freedom of the wage labourer – that constitutes the *raison d'être* of capital in the history of the development of the powers of the human species. Although capital is the historical producer of the powers of directly social labour, it achieves this by subordinating direct productive co-operation to the autonomised movement of social life alienated as an attribute of the material product of labour. In other words, those powers are developed by determining directly social labour as a concrete form of development of the powers of private labour, i.e. as a mode of existence of capital's self-valorisation through the production of relative surplus value.[23] The movement of self-valorisation constitutes capital's *formal specificity*, the necessary social form in which the aforementioned *material* transformation of the production process of human life is historically achieved.[24]

---

[22] Marx 1993, p. 162.

---

[23] In other words, those productive powers are developed by determining personally free subjectivity as a concrete form of its alienated determination. Or, to grasp it from a different angle, by determining the organisation of social labour in the form of direct (i.e. conscious) social relations in the immediate process of production as a concrete form of the essentially *indirect general organisation* of social labour through the valorisation of capital.

[24] The material specificity of the concrete forms of production of relative surplus value has been generally ignored by orthodox Marxism, which tended to reduce the problem to a question of who manages those very forms of the labour process. A classic example of this is Lenin's (1971) claim, after the Russian Revolution, that Taylorism could provide in its immediacy the material forms of the labour process for a socialist society (for a brief account of the evolution of Lenin's changing views of Taylorism throughout his writings, see Scoville 2001). However, it is not just a question of simply noting the specifically capitalist character of the labour process and concluding that they cannot immediately provide the basis for a communist society, as many Marxists have done in opposition to the orthodox uncritical silence on this issue (just to name a few classic works from very different heterodox traditions, see Braverman 1998; Dunayevskaya 1988; Panzieri 1980). The crux of the matter resides in grasping the *relative historical necessity* of those material forms, which certainly express the alienated domination of capital over labour, as a *vanishing* moment in the process of development of human productive subjectivity and, hence, in the production of the necessity of their own supersession. See Marx 1993, pp. 831–2. This, on the other hand, cannot but be overlooked if the critique of capital-determined technology is reduced to the representation of this technological form as a simple weapon in the class struggle, i.e. as an attempt by capitalists to re-impose discipline on the labour process when faced with the insubordination of workers, with capitalist control in turn achieved through the arbitrary imposition of divisions and hierarchies (Cleaver 1979, pp. 109–14, and 1982; Holloway 1991). Seen in this light, the capitalist form of the production process of human life is represented as having no necessity other than an abstract power relation between capitalist and worker in the immediate process of production. Eventually, the logic of such an approach must lead to the very abandonment of the specific notion of the capitalist process of production as the unity of the labour process and the valorisation process, and to its replacement with the abstract unity of the 'technique of production' and

> Just as the social productive power of labour that is developed by co-operation appears to be the productive power of capital, so co-operation itself, contrasted with the process of production carried on by isolated independent producers, or even by small masters, appears to be a specific form of the capitalist process of production. It is the first change experienced by the actual labour process when subjected to capital … This starting point coincides with the birth of capital itself. If then, on the one hand, the capitalist mode of production is a historically necessary condition for the transformation of the labour process into a social process, so, on the other hand, this social form of the labour process is a method employed by capital for the more profitable exploitation of labour, by increasing its productive power.[25]

The significance of this *twofold* character of capital's historical specificity (*social and material*) cannot be overestimated. In effect, overlooking this material determination can only result in depriving the working class of the historical specificity of its revolutionary powers, thus making it impossible to distinguish

---

'technique of dominating those who are producing' (Gorz 1976, p. viii). See also Marglin (1974) and Brighton Labour Process Group (1977) for other examples of extrinsic juxtaposition of power relations and technical forms. For a critique of this kind of approach, see Reinfelder (1980). This perspective actually renders inexplicable the historical specificity of the material forms of the production of relative surplus value. To begin with, it cannot account for the fact that 'co-operation remains the fundamental form of the capitalist mode of production' (Marx 1976g, p. 454). And secondly, as we shall see below, it cannot account for the universal productive subjectivity that such co-operation eventually entails when taking the form of large-scale industry. If the inner motive of capital were to 'dominate workers', it would quite simply refrain from introducing technical changes that under certain circumstances might actually enhance workers' solidarity and that, eventually, lead to its own supersession. But as self-valorising value, capital has no other purpose than producing surplus value, the most potent form of which is the increase in the productivity of labour. In reality, those approaches actually conflate two distinct determinations, both mentioned by Marx in the same section of *Capital*, pertaining, as it were, to different levels of abstraction, namely, the determination of the materiality of the production process as a concrete mode of existence of capital's production of relative surplus value (Marx 1976g, pp. 553–62) – the content – and the deliberate use of machinery by the capitalist as a weapon in the class struggle over the value of labour power (Marx 1976g, pp. 562–3) – the mediating concrete form. The necessity of those material forms is grounded in capital's immanent drive to produce relative surplus value. The class struggle is certainly a necessary mediation in such an alienated development of the productive powers of humanity, but it does not determine it.

[25] Marx 1976g, p. 453.

the proletarian revolution, i.e. the political form taken by the fully conscious organisation of the social production process of human life, from the revolt of slaves against the personal domination of their owner.[26]

In a nutshell, Marx's uncovering of this twofold determination of capital constitutes the first step – but *only* the first step – in the reproduction in thought of the material genesis of the revolutionary subject. On the one hand, we can appreciate now that the conscious organisation of the immediate production process of human life is not, as it appeared when we were before the most abstract determinations of social life synthesised in the commodity form, the abstract negation of our present-day general social relation. However, the determinations unfolded so far also carry a *limit* to the expansion of directly social labour, thereby still determining it as a concrete form of the historical development of the powers of its opposite: private labour.

In effect, although the constitution of simple co-operation represents a step forward in the organisation of human life as a directly collective potency, this social power is not yet the self-conscious product of the direct association of the producers. Instead, it is set into motion with the previous mediation of the sale of their labour power as independent and isolated individuals to the capitalist. Therefore, since 'their co-operation only begins with the labour process, but by then they have ceased to belong to themselves',[27] and their labour now belongs to capital, all the productive powers of labour that spring from the social combination of the workers are transformed into attributes of capital. In their very corporeality as working subjects, i.e. in the materiality of their productive subjectivity, the labourers 'merely form a particular mode of existence of capital' in its movement of valorisation.[28] What is more, not only are those directly social productive powers of co-operation inverted as an attribute of the wage workers' materialised social relation, but its conscious organisation is not even exercised by them but by the immediate personification of self-valorising value, namely, the capitalist. Inasmuch as it is through her/his consciousness and will that the now collective conditions required for the wage labourers' individual labours to take place are posited, the capitalist becomes the conscious incarnation of the direct organisation of the social character of the labour of the group of workers under her/his command. For the workers, this social character thus appears in the ideal form of a 'plan drawn up by the capitalist, and, in practice, as his authority, as the powerful will of a being outside them, who subjects their activity to his purpose'.[29] On the other hand, inasmuch as it is not only oriented to the production of a use value but to the valorisation of capital through the production of surplus value – i.e. through the exploitation of labour – the direction of this process by the capitalist takes a despotic form.[30]

---

[26] See De Angelis (1995) and Holloway (2002b) for examples of such a formalistic understanding of capital. In a way, one could argue that these approaches ultimately remain refined versions of what Loren Goldner in the early 1980s insightfully noted concerning not just twentieth-century 'official Marxism' (broadly conceived to include authors as diverse as Lenin, Bukharin, Baran, Sweezy, Bettelheim), but also 'Western Marxist' currents such as the Frankfurt School, namely, the comprehension of 'capitalism … not [as] a system of valorization, but [as] a system of power', according to which 'capital ceased to be a dynamic and was transformed into a "hierarchy"' (Goldner 1981). The consequence of this is, as Goldner comments concerning 'Monopoly Capital' theory, the production of a theory which ceases to be 'about forces and relations of production', and becomes 'a *sociological* theory of hierarchy and oppression, the balance of forces between the classes in question being a question of struggle and will' (Goldner 1981). Whilst the approaches that constitute the explicit target of Goldner's critique tended directly to ignore the general determination of capital as value-in-process, the interesting thing about works such as those of De Angelis and Holloway referred to above is how they relapse into the same reduction of the critique of political economy to a sociological theory of oppression, *while* at the same time paying lip-service to the categories of Marx's *Capital*. See Goldner (2001, pp. 2–3) for suggestive reflections on the historical conjuncture underpinning this cultural mood of 'middle-class radicalism', which, unlike the Marxian notion of freedom as the fully conscious transformation of necessity, 'conceives of freedom as "transgression", as the breaking of laws, the "refusal of all constraints"'.

The determinations of simple co-operation thereby seem to intensify the power of the capitalist over the worker in the antagonistic direct relationship that they establish in the immediate process of production. This power is not simply the formal result of the separation of the labourer from the objective conditions of labour. Inasmuch as the capitalist concentrates the 'work of directing, superintending and adjusting the co-operative labour of wage-workers',[31] her/his command becomes a *material* prerequisite of the labour process itself. As Marx puts it, 'that a capitalist should command in the field of production is now as indispensable as that a general should command on the field of the battle'.[32] The dependence of the wage labourers upon capital now starts to be expressed even in relation to the materiality of the production process. Far from moving in the direction of the determination of the working class as a revolutionary subject, these developments seem to deepen the latter's subjection to the alienated movement of capital's valorisation.

And yet, the very same alienated form of their co-operation that, furthermore, strengthens the power of the capitalist, engenders a countertendency which presses in the opposite direction to the unchecked imposition of capitalist discipline. In effect, by putting the workers together under the same roof, capital facilitates the establishment of the relations of solidarity through which, as we have seen in the previous chapter, the workers attempt to restrict the consumption of their labour power by the capitalist.[33] However, Marx immediately adds, this intensified resistance does not yet express an absolute limit to the development of the alienation inherent in the capital form. It only increases 'the pressure put on by capital to overcome this resistance'[34] through the development of the despotism of capitalist command in the forms that are peculiar to it.[35] Eventually, capital attempts to break this barrier to its valorisation by revealing 'in practice' that simple co-operation is just one particular figure of the production of relative surplus value 'alongside the more developed ones'.[36]

Capitalist Manufacture and the Material Basis of the Class Struggle over the Full Value of Labour Power

Whatever the historical origins of the production process of capitalist manufacture – i.e. whether it arises from a combination of formerly independent crafts into one collective labour process of a single commodity, or whether its genesis is found in the analytical decomposition of an existing activity into its component parts – the essence of this concrete form of production of relative surplus value consists in the division of the total labour necessary for the production of a determinate use value into particular detail operations. The labour process of an entire commodity now involves the articulation of those differentiated productive functions into a co-ordinated whole. As the resulting different manual tasks involved are assigned to what now become specialised workers, their labour becomes more productive.[37] With this increased productivity of labour, capital's production of relative surplus value is consequently achieved. This increased surplus value is not just the result of the enhanced productivity.

[33] Marx 1976g, p. 449.

[34] Ibid.

[35] Marx 1976g, p. 450.

[36] Marx 1976g, p. 454.

[37] Marx 1976g, p. 458.

Since the latter is the result of the simplification of the required necessary skills, the 'expenses of apprenticeship' are reduced (or almost disappear in the case of the unskilled type of labourer also produced by the development of manufacture). This has the additional result of *decreasing the value of labour power*.[38] Moreover, the fixation of the worker in a single form of activity eliminates the time necessary to change from one sort of activity to the other, permitting capital to *increase the intensity of labour*.[39]

These transformations of the productive subjectivity of the individual labourers have their counterpart in the way in which they are articulated organically as part of a single labour process. In other words, those mutations result in the transformation of the determinations of the collective labourer, which actually becomes 'the item of machinery specifically characteristic of the manufacturing period'.[40] The latter no longer consists in the mere agglomeration of individual productive processes under the same roof. It now becomes a complex, directly social body differentiated into qualitatively distinct partial organs. In turn, these transformations not only make the qualitative articulation of the different individual labours a more complex process. They also determine, as a material necessity of the labour process, the establishment of a quantitative proportionality between the qualitatively different partial organs of the collective labourer. The individual labour of the workers in itself ceases to be productive of commodities. This attribute now belongs to the integration of those particular and partial labours, i.e. to the collective labourer as such.[41] The immediately social character of the production process within the workshop is thus no longer limited to the positing of its objective conditions, but reaches the labouring activity itself, a point that Marx brings out by comparing the determinations of the organisation of the fragment of social labour under the command of an individual capitalist with the general organisation of social labour through the commodity form across society.[42] Furthermore, since the renewal of the production of relative surplus value involves the further development of the division of labour within the workshop, it becomes a law of the valorisation of capital that the number of partial organs comprising the collective labourer – and hence the conscious organisation of social labour – must keep extending.[43]

In this way, capital makes another step forward in the realisation of its civilising mission. However, it still does so by determining directly social labour as a concrete form of development of the powers of private – hence alienated – labour, so that 'anarchy in the social division of labour and despotism in the manufacturing of labour mutually condition each other'.[44] As happened with simple co-operation, all the emerging powers of social labour deriving from this more developed form of human productive co-operation are turned into attributes of capital in its process of self-expansion through the production of relative surplus value.[45] But the subsumption of the powers of living labour under the rule of capital is now not only expressed in that formal inversion between subject and object of social production. With the manufacturing division of labour, the alienated development of the powers of social labour is achieved through the deepening of the material mutilation or degradation of the individual productive subjectivity of wage labourers. As a consequence, this process gives the conscious organisation of social labour within the workshop a *specifically capitalist character*, not only because of its determination as the material bearer of the valorisation of capital and, hence, as an attribute despotically exercised by the capitalist, but by virtue of the materiality of the production process itself. In effect, the specialisation of the worker in a single operation means that a one-sided aspect of human personality is developed, undermining all the potential universality of human productive capacities. The wage labourer thus becomes a fragmented individual. If with simple co-operation the productive subjectivity (hence activity) of the worker formally became a *mode of existence* of capital, now her/his *corporeality as a working subject*, in its very materiality, becomes a *result* of the production of relative surplus value.

> While simple cooperation leaves the mode of the individual's labour for the most part unchanged, manufacture thoroughly revolutionizes it, and seizes labour-power by its roots. It converts the worker into a crippled monstrosity by furthering his particular skill as in a forcing-house, through the suppression of the whole world of productive drives and inclinations, just as in the states of La Plata they butcher a whole

---

[44] Marx 1976g, p. 477. This point about the 'inner connection' between the general unconscious regulation of social life through the valorisation of capital and the despotic nature of the conscious plan inside the workshop (later on, the factory) has been correctly emphasised by Dunayevskaya and her followers against the uncritical celebration of the latter by orthodox Marxists (Dunayevskaya 1988; Hudis 1998, p. 103).

[45] Marx 1976g, p. 486.

> beast for the sake of his hide or his tallow. Not only is the specialized work distributed among the different individuals, but the individual himself is divided up, and transformed into the automatic motor of a detail operation, thus realizing the absurd fable of Menenius Agrippa, which presents man as a mere fragment of his own body.[46]

The directly social powers of the collective labourer are thus developed *at the expense* of the productive attributes of the individual worker.[47] This specifically capitalist concrete form of human labour power means that the direct producer actually further *loses* the productive consciousness of the unity of the labour process of the entire commodity – now immediately social within the workshop – which the simple commodity producer still preserved. The productive consciousness of the unity of the collective labourer becomes an attribute personified by the capitalist, the workers only keeping conscious control of the ever more partial individual activity under their responsibility, now only a fragment of the total labour process of the determinate use value at stake.

> The knowledge, the judgement, and the will, which, even though to a small extent, are exercised by the independent peasant or handicraftsman, in the same way as the savage makes the whole art of war consist in the exercise of his personal cunning, are faculties now required only for the workshop as a whole. The possibility of an intelligent direction in production expands in one direction, because it vanishes in many others. What is lost by the specialized workers, is concentrated in the capital that confronts them. It is a result of the division of labour in manufacture that the worker is brought face to face with the intellectual potentialities [*geistige Potenzen*] of the material process of production as the property of another and as a power that rules over him. This process of separation starts in simple co-operation, where the capitalist represents to individual workers the unity and the will of the whole body of social labour. It is developed in manufacture, which mutilates the worker, turning him into a fragment of himself. It is completed in large-scale industry, which makes science a potentiality for production which is distinct from labour and presses it into the service of capital.[48]

---

[46] Marx 1976g, pp. 481–2.

[47] Marx 1976g, p. 483.

[48] Marx 1976g, p. 482.

In this process, the alienation of the human powers of the labourer as attributes of capital reaches a further stage. What the workers lose with their subjection to the manufacturing division of labour is that specific human attribute that, as Marx discusses in Chapter 7 of *Capital* but had claimed as early as in the 1844 *Manuscripts*, distinguishes the human form of the appropriation of the forces of nature from its animal form, namely, the 'spiritual powers' of the production process or the conscious capacity to organise its rationality and purpose. Concerning the total labour process in which the workers take part, that which 'distinguishes the worst architect from the best of bees'[49] is stripped of their productive subjectivity. In this specifically material sense, capital is thus an *inhuman* social form of development of human productive powers.[50]

The subordination of workers to the rule of capital and the dependence of the production process on the direction of the capitalist that already started to appear with simple co-operation is thereby intensified in the division of labour of manufacture. The conversion of the worker into 'the automatic motor of a detail operation' means that the wage labourer not only has to sell her/his labour power for not possessing the objective means necessary for exercising her/his subjective productive capacities. The crippling of her/his productive abilities means that 'now his own individual labour power withholds its services unless it has been sold to capital'.[51] The worker whose labour power is now the product of the production of relative surplus value does not even know how to produce an entire commodity by herself/himself. She/he becomes increasingly forced to sell her/his labour power to capital as the only means to reproduce her/his life.

And yet, these very same determinations, which appear to weaken the workers' resistance to capital's restless striving for relative surplus value, engender a barrier to this affirmation of the materialised social relation as the concrete subject of the process of production of human life. The key to the comprehension of this contradiction immanent in capital's valorisation process lies in the very essence defining the division of labour of manufacture:

> Whether complex or simple, each operation has to be done by hand, retains the character of a handicraft, and is therefore dependent on the

---

[49] Marx 1976g, p. 284.

[50] This inhumanity reaches its extreme with capital's production of a relative surplus population, comprising the workers who are literally prevented from the exercise of their own species being.

[51] Marx 1976g, p. 482.

> strength, skill, quickness and sureness with which the individual worker manipulates his tools.[52]

In other words, the production process of manufacture still depends on the crucial intervention of the handicraft expertise of the labourer. The structure of co-operation is purely subjective, gaining articulation only through the bodily motion of the individual workers as the fundamental material subjects of that collective labour process. The fluidity of the labour process (hence, of the valorisation process which it sustains) depends on the willingness of individual workers to act as partial organs of the collective labourer. Hence, this lack of 'an objective framework independent of the workers themselves'[53] as the foundation of manufacture provides a *material basis* for an empowered resistance of workers in the antagonistic relation they establish with capital.[54] This material basis, however, does not yet provide the class struggle with a different *qualitative* determination other than being the concrete form which secures the realisation of the full value of labour power (whether being the form of the expropriation of the bourgeoisie, or being the form of the abolition of capital). It only increases the *magnitude* of the force borne by the working class in its political action.[55] Thus, the insubordination of the workers constitutes an obstacle to the valorisation of capital which does not yet express the need for the development of the productive powers of social labour to transcend its alienated form as production of relative surplus value. As Marx makes clear, it only forces the latter to develop into a concrete form which undermines that material basis underlying the said obstacles to the domination of capital, namely, the system of machinery.

---

[52] Marx 1976g, p. 458.

[53] Marx 1976g, p. 489.

[54] Marx 1976g, p. 490. Note, however, that this material basis also engenders a countertendency to that increased political force through the fragmentation of workers caused by their insertion into a wage hierarchy revolving around skills.

[55] The relevance of this determination is not confined to the historical comprehension of the now very distant past used by Marx as illustration in *Capital*. It is crucial, for instance, to understand the peculiar political power of the workers during the so-called Fordist cycle of accumulation (Iñigo Carrera 2008, pp. 63–4). In effect, especially concerning the production of machinery itself, and however degraded the productive subjectivity of workers, Fordist methods still involved the subordination of the adjustment and calibration of machines and even the assembling process itself to the manual skills of labourers.

> One of its [manufacture's] most finished products was the workshop for the production of the instruments of labour themselves, and particularly the complicated pieces of mechanical apparatus already being employed … This workshop, the product of the division of labour in manufacture, produced in its turn – machines. It is machines that abolish the role of the handicraftsman as the regulating principle of social production. Thus, on the one hand, the technical reason for the lifelong attachment of the worker to a partial function is swept away. On the other hand, the barriers placed in the way of the domination of capital by this same regulating principle now also fall.[56]

As we can see, the form of manufacture taken by the immediate production process further develops the contradictions and tendencies immanent in the movement of capital as alienated subject which were insinuated by the determinations of simple co-operation. In the first place, both capital's world-historical role in the development of the species powers of humanity and its contradictory march forward in the historical process of its realisation acquire a clearer expression. Thus, in giving an immediately social character not only to the 'objective factor' of the labour process but also to the 'subjective factor', capital shows its historical tendency to produce at least the first of the two general attributes of productive subjectivity which, as mentioned in the introduction, are crucial for the constitution of 'really free working' (and hence for the abolition of capital itself). However, the division of labour of manufacture also reveals the contradictory form in which that process unfolds. In the first place, the socialisation of labour is still achieved by formally determining immediately social labour as a concrete form of the self-movement of valorisation of capital. But additionally, this contradiction acquires a further *material* expression in the mutilation of the individual character of the productive subjectivity of wage labourers, which is revealed as a historical mediation in the production of direct producers with the material powers consciously to organise their social life process as a fully self-conscious collective labour power.

In the second place, we can now appreciate more clearly that the determinations of the class struggle over the value of labour power are not exhausted in the *formal* subsumption of labour to capital. If one stops short at that level of abstraction as developed in Chapter 10 of *Capital*, the appearance arises that the balance of class forces – and so, for instance, the duration of the working day – is purely contingent. However, Marx's discussion of simple co-operation and, even more so, of the division of labour of manufacture, makes evident that there is a *material basis* for the respective political power of each class in struggle.[57] Thus, the further unfolding of the determinations of the valorisation of capital reveals that the materiality of the forms of the *real* subsumption of labour to capital *mediate* not only the transformative power of the workers' political action determined as the form of *capital's transcendence* (a point I have been anticipating but still need to prove), but also that of its role as moment of *capital's reproduction*.[58]

---

[56] Marx 1976g, p. 491.

I have followed the transformations of the collective labourer brought about by capital through the first two forms of existence of the production of relative surplus value, namely, simple co-operation and the division of labour of manufacture. From the perspective of the development of the revolutionary subjectivity of the working class, these changes in the materiality of social life still do not equip the workers with the material powers to abolish capital synthesised in the two general productive attributes necessary for 'really free working' mentioned in the introduction. Although their individual labours increasingly become directly social, their work of material production is evidently *not* of a 'scientific and general character'. First, the very 'technically narrow basis' of manufacture – i.e. handicraft – 'excludes a really scientific division of the production process into its component parts'.[59] Secondly, far from developing workers with *general* productive attributes, we have seen that manufacture involves an individual labour of a *particularistic* kind.[60] The search for the determinations of revolutionary subjectivity must therefore carry on. Let us then turn to Marx's discussion of large-scale industry and see if those determinations are contained there.

---

[57] In those two chapters, Marx refers to the resistance of workers in general. Specifically concerning the length of the working day, the plenitude of this determination becomes manifest in the chapter on machinery and large-scale industry. As I have mentioned in the previous chapter, in the chapter on large-scale industry Marx shows without ambiguity that the *material* determination behind the normal duration of the working day lies in the inverse relation between its length and the intensity of labour. Grossmann, in the final considerations to *The Law of Accumulation and Breakdown of the Capitalist System* (unpublished in the abridged English translation), correctly highlights the direct relation between the intensification of labour and the increase in the value of labour power, thus showing (in opposition to Kautsky, Luxemburg and Bukharin) the existence of a material determination underlying the success of working class struggles over real wages (Grossmann 1979, pp. 374–84).

[58] More generally, this also can serve to illustrate once again the importance of the dialectical method as the 'reproduction of the concrete by means of thought'. Here we can appreciate very clearly why we can see through all appearances presented by a determinate social form (in this case, the class struggle) only by grasping it in the *totality* of its determinations, i.e. by making the full, laborious journey from the abstract to the concrete. Laziness and/or hastiness of thought thereby translates into impotence to fully comprehend and hence transform the concrete; which, as Marx reminds us in the *Grundrisse*, is such precisely for being 'the concentration of many determinations, hence the unity of the diverse' (Marx 1993, p. 101).

Large-Scale Industry and Workers' Productive Subjectivity in *Capital*

As I have been arguing, the guiding thread running through Marx's exposition of the concrete forms of production of relative surplus value resides in the revolutions to which capital subjects the productive subjectivity of the doubly free labourer as the means for the multiplication of its power of self-valorisation. However, it is not there that Marx's presentation of the determinations of large-scale industry begins. The reason for this derives from the very starting point of the production of relative surplus value through the system of machinery characterising large-scale industry. As Marx points out, if in manufacture the point of departure of the transformation of the material conditions of social labour was productive subjectivity as such (with the transformation of the instrument of labour, in the form of a specialisation, determined as a result of the former), in large-scale industry the transformation of the instrument of labour constitutes the starting point, the transformation of the wage labourer being its result.[61]

Marx presents the essence of this transformation of the human labour process by developing the specific materiality of machinery, in particular vis-à-vis the labour process in manufacture. In reality, the simplest determination of that difference was already anticipated by Marx in the transition contained in the previous chapter of *Capital*, where the necessity of the development of machinery was laid bare. I am referring to capital's need to do away with the subjective basis of manufacture through the development of an 'objective framework' for material production, independent of the manual expertise and immediate practical knowledge of workers. In brief, it is about giving an objective form to the powers of social labour springing from direct productive cooperation.[62]

---

[59] Marx 1976g, p. 458.

[60] The constitution of a section of unskilled labourers in manufacture, that is, of workers whose speciality is the lack of all specialisation (Marx 1976g, p. 470), does constitute a first insinuation of the emergence of labourers with universal productive attributes. However, this universality is not the expression of an expanded productive subjectivity of wage labourers, but of an absolute degradation. Moreover, the number of unskilled universal workers required by manufacture remains relatively small, the essence of the latter being expressed mainly in workers with particularistic development of their productive attributes. Universal workers, on the contrary, are the most genuine product of the system of machinery.

[61] Marx 1976g, p. 492.

The twofold material specificity of the machine thereby springs from the objectification of both the – however restricted – knowledge and manual skills and strength of the manufacturing labourer. On the one hand, capital strives to substitute the movement of the forces of nature for that of the human hand as the immediate agent in the transformation of the object of labour into a new use value. On the other hand, it attempts to displace the immediate subjective experience of the worker as the basis for the conscious regulation of the labour process, i.e. as the basis for knowledge of the determinations of the latter. This implies, in the first place, the need to turn the production of that knowledge into an activity which, whilst clearly remaining an inner moment of the organisation of social labour, nonetheless acquires a differentiated existence from the immediacy of the direct production process. Coupled with the need to objectify it as a productive power directly borne by the 'dead labour' represented in the machine, that knowledge must necessarily take the general form of *science*. As Marx summarises,

> As machinery, the instrument of labour assumes a material mode of existence which necessitates the replacement of human force by natural forces, and the replacement of the rule of thumb by the conscious application of natural science.[63]

We can now start to appreciate how capital advances, for the first time in human (pre)history, in the generalisation of the application of science as an immediate potency of the direct process of production.[64]

---

[62] Marx 1976g, pp. 490–1.

[63] Marx 1976g, p. 508.

[64] I say 'generalisation' because capital did not invent natural science. However, by converting science into the general principle of material production, the production of relative surplus value enormously fostered its development and continuous progress. And yet, it can only develop scientific thought within the limits springing from its determination as an alienated social form. I shall come back to this crucial issue below.

> The employment of the natural agents – their incorporation so to speak into capital – coincides with the development of *scientific knowledge* as an independent factor in the production process. In the same way as the production process becomes an *application of scientific knowledge, so*, conversely, does science become a factor, a function so to speak, of the production process. Every invention becomes the basis of new inventions or new, improved methods of production. It is the capitalist mode of production which first puts the natural sciences to the service of the direct production process, while, conversely, the development of production provides the means for the theoretical subjugation of nature.[65]

Through this concrete form of production of relative surplus value, capital starts to move in the direction of the social constitution of the second general attribute of productive subjectivity which the coming into existence of 'really free working' presupposes, namely, the determination of productive consciousness as scientific, thereby objective, in character. Note, however, that at this stage of the exposition, scientific knowledge does not appear directly as productive activity, but only as already objectified in the form of the machine, that is, simply as a presupposition for the latter's existence.

Large-scale industry does not only move forward in the constitution of the scientific character of production. It also fosters the deepening of the other material determination of 'really free working', that of labour becoming directly social. In effect, with the system of machinery the co-operative character of labour comes to be a presupposition of the actual exercise of productive activity, whose necessity springs from the materiality of the instrument of labour itself. What is more, it is possible to see now that those two general attributes are not extrinsically related, but each one presupposes the other.

> Large-industry … possesses in the machine system an entirely objective organization of production, which confronts the worker as a pre-existing material condition of production … Machinery, with the few exceptions to be mentioned later, operates only by means of associated labour, or labour in common. Hence the co-operative character of the labour process is in this case a technical necessity dictated by the very nature of the instrument of labour.[66]

---

[65] Marx 1994, p. 32.

[66] Marx 1976g, p. 508.

Thus far, then, these are the fundamental aspects of Marx's exposition of the *material* specificity of the production process of capital based on the system of machinery, i.e. the transformations it suffers in its aspect as a process of production of use values. But the process of production of capital is such for being the unity of the labour process and the valorisation process. Hence, Marx's presentation goes on to develop the specific impact of the system of machinery on the latter, which can be summarised in the following points:

> *As happened with all the productive powers deriving from the exercise of human productive co-operation in an immediately social form (whether in its simple form or through the manufacturing division of labour), the use of scientific discoveries costs capital nothing. They are natural forces of social labour that capital appropriates for free for the purpose of its valorisation.[67]
>
> *However, the productive consumption of the results of science involves the utilisation of ever more complex and costly means of production in an ever increasing scale. The capitalist appropriation of science thus entails an expanding magnitude of the average capital disbursement necessary to set the production of relative surplus value, springing in this case from the growth of constant capital.[68]
>
> *This increment in the magnitude of constant capital is evidently reflected in the value of the product. However, the twofold nature of the capitalist production process as the unity of the labour process and the valorisation process means that this reflection is not simple or immediate. Machines do not create value, but living labour transfers their value to the product; and it does so only in proportion to 'its average daily wear and tear'.[69] On the other hand, they enter as a whole in their determination as a material factor of the labour process. This 'difference between the mere utilisation of the instrument and its depreciation',[70] and expression of the powers of the objectification of past labour, is also appropriated gratuitously by capital.

---

[67] Ibid.

[68] Marx 1976g, p. 509.

[69] Marx 1976g, p. 510.

[70] Marx 1976g, pp. 509–10.

> *However attractive these gratuitous services to capital's valorisation brought about by the introduction of machinery might be, the latter faces a specific limit *stricter* than the generically mercantile one given by the difference between the labour the machine costs and the labour it saves.[71] The reason for this is founded in capital's valorisation taking concrete form through the appropriation of *unpaid* surplus labour. Thus, for the capitalist, the limit to the use of the machine 'is therefore fixed by the difference between the value of the machine and the value of *labour-power* replaced by it'.[72]

With this, Marx's presentation exhausts the novel determinations brought about by the system of machinery to the production process as they pertain to its 'objective factor'. What necessarily follows, then, is the investigation of the impact of these transformations on the 'subjective factor' of the labour process, that is, on the worker.

In the third section of the chapter on large-scale industry, Marx initially presents what he refers to as only 'some general effects' of the system of machinery on the worker, that is, those changes that can be discussed without developing the specific form in which the 'human material is incorporated with this objective organism'.[73] In other words, these are the effects whose development does not involve any new *qualitative* determination in the productive subjectivity of workers. Rather, they refer to the *quantitative* changes that machinery brings about in capital's valorisation process as a process of exploitation of living labour. These include: the quantitative extension of the mass of exploitable labour power through the incorporation of female and child labour; the tendency to prolong the working day; and the tendency to increase the intensive magnitude of the exploitation of human labour.

---

[71] Marx 1976g, p. 515.

[72] Marx 1976g, p. 515, my emphasis. This specifically capitalist limit to the introduction of machinery thus not only evidences the *restricted* character of this alienated social form of development of the material productive forces of society vis-à-vis a classless, communist society (Marx 1976g, p. 515, n. 16) – incidentally, a determination completely overlooked by bourgeois economists who, like Schumpeter and his contemporary disciples (Schumpeter 1934 and 1947; Dosi et al. 1988), make a great fuss about the technological dynamism of the capitalist mode of production. See Smith (2004) for a Marxist critique of Neo-Schumpeterian economics, and Bellofiore (1985) for a comparison between Marx and Schumpeter. In addition, this also sheds light on the contradictory forms in which capital unfolds its nonetheless undeniable dynamism in the development of the productive powers of social labour. As Marx points out, the development of the system of machinery in some branches of industry may create such a surplus labour force in others that capitalists could force down wages below the value of labour power as a source of extra profit, thereby *hindering* the development of the productive forces in those sectors of production (Marx 1976g, p. 516). Finally, this also gives the 'exact demonstration' of the progressive character of the class struggle over the value of labour power as an active force in the development of the productive powers of society and, therefore, in the production of the material conditions for its more concrete determination as the form of the abolition of capital.

[73] Marx 1976g, p. 517.

It is in section 4, through the presentation of the functioning of 'the factory as a whole', that Marx starts to unfold the specific *qualitative* determinations of the productive subjectivity of large-scale industry. The discussion of a passage from Ure serves Marx succinctly to identify the most general determination of the factory as the sphere of capitalist society where the conscious regulation of an immediately social production process takes place. A conscious regulation, however, that is determined as a concrete form of the *inverted general social regulation* as an attribute of the materialised social relation in its process of self-expansion. In the factory – and this is the issue that Ure's definition overlooks – this inverted social existence reaches a further stage in its development by acquiring a 'technical and palpable reality'.[74]

Thus, the scientific conscious regulation of social labour characterising large-scale industry is not an attribute borne by those workers performing direct labour in the immediate production process. For them, those powers exist already objectified in the system of machinery, to whose automatic movement they have to subordinate the exercise of their productive consciousness and will, to the point of becoming 'its living appendages'.[75] Large-scale industry consequently entails an enormous scientific development of the 'intellectual faculties of the production process' only by exacerbating their separation from direct labourers. In its mode of existence as a system of machinery, the product of labour comes to dominate the worker in the direct process of production not only formally but even materially as well. Capital thus appears to those workers as the *concrete material subject* of the production process itself.

As the personification of the system of machinery acting as a material mode of existence of capital, the capitalist represents before the direct labourers the consciousness of the unity of their productive co-operation. The conscious articulation of their directly social labour therefore appears as the product of the capitalist's autocratic will which, given the increasing complexity and scale of the co-operative production process under her/his command, acquires an objective form in the factory code and its 'barrack-like discipline'.[76]

---

[74] Marx 1976g, p. 548.

[75] Ibid.

With all these elements, we can now turn to summarise the specific determination of the productive subjectivity of the worker of large-scale industry. In (*tendentially*) doing away with the need for all specialised skill and knowledge of workers, the production of relative surplus value through the system of machinery gives the development of their productive subjectivity the concrete form of an *absolute degradation*. In this brutal way, and in opposition to the *particularism* of the subjectivity of the wage labourer of manufacture, large-scale industry begets, as its most genuine product, a *universal worker*, that is, a productive subject capable of taking part in any form of the human labour process. In the words of Marx,

> Hence, in place of the hierarchy of specialised workers that characterizes manufacture, there appears, in the automatic factory, a *tendency* to equalize and reduce to an identical level every kind of work that has to be done by the minders of the machines; in place of the artificially produced distinctions between the specialized workers, it is natural differences of age and sex that predominate.[77]

With this tendency to the production of workers who are capable of working with any machine, the simple material or technical necessity for the lifelong attachment of individuals to a single productive function disappears.[78] However, insofar as machines become specialised into certain particular productive functions, the persistence of the division of labour in the factory is still technically *possible*. Indeed, Marx argues, the exploitative relation between capitalists and workers that mediates the development of the material productive forces of social labour as an alienated attribute of its product, leads to the reproduction of the 'old division of labour' in an even more hideous fashion.[79] Large-scale industry's tendency to produce an increasingly universal worker is thereby realised in the concrete form of its negation, that is, by multiplying the spaces for the exploitation of living labour on the basis of an exacerbation of 'ossified particularities'. Thus, the individual capitalist could not care less about the disappearance of the technical necessity for a particularistic development of the worker's productive subjectivity. Under the pressure of competition, his/her only individual motive is the production of an extra surplus value. If he/she can obtain it by attaching the worker to 'the lifelong speciality of serving the same machine',[80] so she/he will. In effect, the reproduction of the division of labour under the new technical conditions implies that a lower value of labour power can be paid – since 'the expenses necessary for his [the workers'] reproduction' are 'considerably lessened'. In addition, it implies that a greater docility on the part of the exploitable human material is induced – since 'his helpless dependence upon the factory as a whole, and therefore upon the capitalist, is rendered complete'.[81]

---

[76] Marx 1976g, p. 549.

[77] Marx 1976g, p. 545.

[78] Marx 1976g, p. 546.

[79] Marx 1976g, p. 547.

It is crucial at this juncture to be clear about this contradictory movement between universality and particularity of the determinations of the productive subjectivity of large-scale industry. Paraphrasing Marx, here, as everywhere else, we must distinguish between the general tendency of capital accumulation and the concrete forms in which the essence of the historical movement is realised. *Thus, the essential determination which, as we shall see, expresses the reason to be of the capitalist mode of production, lies in the tendency to universalise the productive attributes of wage labourers*. This is the general movement of the production of relative surplus value through the system of machinery which underlies – hence, gives unity to – the variegated forms that the labour process presents in the course of capitalist development.[82] In order to substantiate this, let us now move ahead in this reading of Marx's investigation of large-scale industry to the point in *Capital* where he further unfolds the movement of the identified contradiction, i.e. to the subsequent discussion of factory legislation in section 9 of this same chapter.[83]

---

[80] Ibid.

[81] Ibid.

[82] Again, this point can help us highlight the fundamental importance of the twofold movement of the dialectical method (analytic and synthetic) underlying its power both to penetrate the surface appearances of reality in order to discover the essence of social forms, and to unfold the necessity of the concrete forms in which that essential moment is realised. Regarding the capitalist labour process, the dialectical method can avoid the twin shortcomings present in the Marxist literature of both a one-sided empiricist focus on its more concrete forms – which substitutes a radical industrial sociology for a proper dialectical investigation (Burawoy 1979 and 1985; Edwards 1979) – and the speculative, unmediated imposition of the general determination on concrete forms which still involve its negation – as happens, for instance, with the 'immaterial labour' thesis popularised by Negri and Hardt's *Empire* (2000, pp. 28–30), and originally coming from their and their colleagues' work around the journals *Futur Antérieur* and *Multitudes* (Lazzarato 1996; Lazzarato and Negri 1991). An empirical study informed by such an approach can be found in Corzani, Lazzarato et al. (1996).

Marx's exposition starts by reminding the reader of the most general determination of factory legislation as the mode of existence of the *general* conscious regulation of social labour as an alienated power of the accumulation of capital, i.e. not simply *within* each private fragment of the total social capital but to the establishment of the general conditions which must be presupposed by all of them. This further illustrates the point I made earlier in the discussion of the legal regulation of the duration of the working day by the capitalist state: the automatism of the movement of the indirect organisation of social labour through the valorisation of capital engenders the general direct regulation (i.e. its negation) as its necessary product.

---

[83] In my view, Marx's presentation is not fully clear and consistent in distinguishing between essential determination (and therefore general tendency) and concrete from in which it is realised. This lack of clarity probably stems from the uneasy coexistence of systematic and historical moments in the exposition. Thus, he firstly presents the general determination of the productive subjectivity of large-scale industry (namely, its universality) 'in its purity', without necessarily implying that it has been fully realised in its historical concrete forms. However, in his subsequent empirical illustrations he seems to treat the general determination as an immediate actuality. He therefore posits the persistence of the particularistic development of productive subjectivity as '*artificially*' reproduced by superimposing the division of labour where its technical necessity has actually disappeared. See Marx 1976g, pp. 546–7, where he remarks that the insignificance of 'on-the-job' skills required for machine work has done away with the need to bring up a special kind of worker and that the attachment of the worker to a single specialised machine represents a 'misuse' of the latter. While this might have been more or less the case in the particular industries that he discusses, this was by no means the general situation of large-scale industry in his time. The general tendency for a universal productive subjectivity is realised only *gradually* in the historical course of capital development. In this sense, the technical necessity for particularistic attributes of labour power is not done away with overnight. Without a doubt, the historical development of large-scale industry registers a tendency for the degradation of experienced-based ('tacit') knowledge of the determinations of the labour process. However, the progress of capitalist automation has so far involved the recreation of the technical necessity for certain (albeit increasingly more limited) particularistic development of productive subjectivity. Thus, even during the so-called 'Fordist' cycle of accumulation, the full mastery of machines required a relatively lengthy learning process achieved by shadowing a skilled operator. Only with the more recent wave of computer-based automation have particularistic or experienced-based skills significantly lost their former centrality (without, however, fully disappearing). On these recent transformations of the labour process, see Balconi 2002.

> Factory legislation, that first conscious and methodical reaction of society against the spontaneously developed form of its production process, is, as we have seen, just as much the necessary product of large-scale industry as cotton yarn, self-actors and the electric telegraph.[84]

But if in its *material content* this determination of the production of relative surplus value shows its progressive character as a form of development of the productive powers of social labour, its concrete realisation as state regulation – in turn, only imposed upon the immediate personifications of capital with the mediation of the class struggle – reveals the limits springing from its *alienated form*. Hence, as Marx points out, the fact that factory acts cannot go beyond only meagre provisions 'strikingly demonstrates that the capitalist mode of production, by its very nature, excludes all rational improvement beyond a certain point'.[85]

The crucial point for my argument is that section 9 completes (as far as *Capital* is concerned) the development of the specific determinations of the productive subjectivity of large-scale industry. In effect, Marx's exposition in section 4 had left the dialectical presentation with an unresolved contradiction between large-scale industry's general tendency for universality and the exacerbation of the particularism of the division of labour that, left to the unrestrained will of individual capitalists, it allowed. In addition, we shall see how this discussion leads Marx, for the first time in his dialectical exposition, to uncover the revolutionary historical potentialities carried by this specifically capitalist form of human labour power.

The movement of 'the contradiction between the division of labour under manufacture and the essential character of large-scale industry'[86] acquires a first expression in the establishment of compulsory elementary education for working children. As Marx points out, the unchecked exploitation of child labour by individual capitals led not only to the 'physical deterioration of children and young persons',[87] but also to an artificially produced intellectual degeneration, which transformed 'immature human beings into mere machines for the production of relative surplus-value'.[88] Since 'there is a very clear distinction between this and the state of natural ignorance in which the mind lies fallow without losing its capacity for development, its natural fertility',[89] these excesses of the capitalist exploitation of child labour power eventually reacted back on the very capacity of valorisation of total social capital by jeopardising the existence of the future generation of adult workers in the 'material and moral conditions' needed by capital accumulation itself. This is illustrated by Marx through a discussion of the case of the English letter-press printing trade, which, before the introduction of the printing machine, was organised around a system of apprenticeship in which workers 'went through a course of teaching till they were finished printers' and according to which 'to be able to read and write was for every one of them a requirement of their trade'.[90] With the introduction of printing machines, however, capitalists were allowed to hire children from 11 to 17 years of age, who 'in a great proportion cannot read' and 'are, as a rule, utter savages and very extraordinary creatures'.[91] These young workers were day after day attached to the simplest of tasks for very long hours until being 'discharged from the printing establishments' for having become 'too old for such children's work'.[92] Those then 17-year-old workers were left in such intellectual and physical degradation that they were unfit to provide capital, *even in the same factory*, with the miserably restricted productive attributes that it required from its immediate source of surplus value, namely, human labour power.

---

[84] Marx 1976g, p. 610.

[85] Marx 1976g, p. 612. The uncritical glorification of the advance in the state regulation of social production by 'state socialists' (whether in its reformist or 'revolutionary' guise) grasps the content of this process without being aware of its alienated form. The abstract critique of 'libertarian' communist currents grasps the oppressive nature of the form but ignores that, in this way, a progressive content realises itself.

[86] Marx 1976g, p. 615.

[87] Marx 1976g, p. 520.

The education clauses of the factory legislation allow Marx not only to dispel any doubt about capital's 'universal vocation' in its transformation of human productive subjectivity. They also serve to highlight, for the first time in his whole dialectical exposition, that it is *only* the development of *that* specific form of human productive subjectivity that expresses capital's historic movement in the production of the material powers for its own supersession as the general social relation regulating human life.

> As Robert Owen has shown us in detail, the germ of the education of the future is present in the factory system; this education will, in the case of every child over a given age, combine productive labour with

> instruction and gymnastics, not only as one of the methods of adding to the efficiency of production, but as the only method of producing fully developed human beings.[93]

Notice, however, that Marx makes clear that the education clauses represent the *germ* – and just that – of the 'education of the future'. To put it differently, Marx's discussion aims at showing *both* that the social forms of the future are effectively carried as a potentiality by the productive subjectivity of large-scale industry under consideration *and* that, with the determinations unfolded so far, that potentiality is not yet immediate. On the contrary, in their 'paltriness', the education clauses reveal that these determinations are far from being a 'method of producing fully developed human beings'. Rather, they are forms of positing individuals whose productive subjectivity is still trapped within the miserable forms imposed by the reproduction of the conditions for capital's valorisation. Other material transformations are still needed to mediate the development of those germinal elements into their plenitude.

The total social capital's necessity to produce universal workers is not exhausted by the obstacles to its valorisation posed by the division of labour within the workshop. As Marx remarks, 'what is true of the division of labour within the workshop under the system of manufacture is also true of the division of labour within society'.[94] In effect, inasmuch as the technical basis of large-scale industry is essentially revolutionary, it entails the permanent transformation of the material conditions of social labour and, therefore, of the forms of exertion of the productive subjectivity of individual workers and of their articulation as a directly collective productive body.[95] This continuous technical change thereby requires individuals who can work in the ever-renewed material forms of the production of relative surplus value. 'Thus', Marx concludes, 'large-scale industry, by its very nature, necessitates variation of labour, fluidity of functions, and mobility of the worker in all directions'.[96] However, he also points out again how the general organisation of social production through the valorisation of independent fragments of social capital negates the immediate realisation of this tendency for an all-sided development of individuals.[97] The private fragmentation of social labour, and its reified social mediation through the capital form, permits the reproduction of 'the old division of labour with its ossified particularities'.[98] Thus, it gives the imposition of variation of labour the form of 'an overpowering natural law, and with the blindly destructive action of a natural law that meets with obstacles everywhere'.[99] In this contradictory form, the realisation of large-scale industry's tendency to produce universal workers nonetheless marches forward, also revealing that it is in the full development of this determination that this alienated social form finds its own *absolute limit*.[100] In other words, that it is in the fully expanded universal character of human productive subjectivity that the *material basis* for the new society rests.

[93] Marx 1976g, p. 614.

[94] Marx 1976g, p. 615.

[95] Marx 1976g, p. 617.

[96] Marx 1976g, p. 617.

[97] Bellofiore (1998) provides suggestive reflections on this question.

> This possibility of varying labour must become a general law of social production, and the existing relations must be adapted to permit its realization in practice … the partially developed individual, who is merely the bearer of one specialized social function, must be replaced by the totally developed individual, for whom the different social functions are different modes of activity he takes up in turn.[101]

With this discussion Marx unfolds the way in which the general necessities of the reproduction of the total social capital – in this case, workers bearing a universal productive subjectivity – clash with its concrete realisation through the private actions of individual capitals (which strive for the perpetuation and exacerbation of the particularistic development of productive subjectivity). Moreover, we see how this contradiction moves by determining the working class as the personification of the mediated necessities of the valorisation of capital, the latter providing the material and social foundation for proletarian political power.

[98] Marx 1976g, p. 617.

[99] Marx 1976g, p. 618.

[100] Marx 1976a, p. 617.

[101] Marx 1976g, p. 618. For postmodern social thought, any claim that there is something progressive in capital's tendency to produce universal subjectivities can only represent a totalitarian attack by Western metaphysics of the subject aimed at suppressing the ontologically irreducible difference on which human subjectivity is predicated. In the same vein as Adam Smith could not distinguish labour from alienated labour and therefore saw productive activity as intrinsically a sacrifice, postmodern social thought cannot distinguish the progressive nature of the development of the universality of human subjectivity as such from the alienated capitalist form in which the conditions for its realisation are historically achieved, i.e. from the alienated universality of the determination of human beings as *personifications*. See Goldner 2001, pp. 91–7, for interesting reflections on this issue.

In effect, the development of large-scale industry makes the possession of a universal subjectivity a matter of survival for the members of the working class since, as evidenced by the aforementioned case of the printing trade workers, only in that way can they be in a position to sell their labour power to capital (thereby turning the alienated necessities of social capital into an immediate need for their social and material reproduction). Thus, workers have to 'put their heads together' again and, through their struggle as a class, force the capitalist state to 'proclaim that elementary education is a compulsory precondition for the employment of children'.[102] But what is elementary education if not a – certainly very basic – step in the formation of future *universal workers*? That is, in the development of productive attributes that equips the labourer to work not in this or that particular aspect of the immediately social labour process of the collective labourer of large-scale industry, but in whatever task that capital requires from her/him?[103]

The total social capital's need for universal workers thereby provides another material basis for the political power of the working class in its confrontation with the capitalist class over the conditions of its social reproduction. In this first expression of that relation between large-scale industry and workers' power represented by the Factory Acts, the class struggle does not appear to transcend its most general determination as the form of the buying/selling of the commodity labour power at its value, which Marx unfolds in Chapter 10 on 'The Working Day'. Yet Marx advances the proposition that, when concretely developed, that tendency towards universal productive subjectivity will eventually provide the class struggle with expanded transformative powers, namely, those necessary for the establishment of the workers' 'political supremacy' as a class.

> Though the Factory Act, that first and meagre concession wrung from capital, is limited to combining elementary education with work in the factory, there can be no doubt that, with the inevitable conquest of polit-

---

[102] Marx 1976g, p. 613.

[103] Recent historical developments of machine-based production have confirmed the general tendency identified by Marx: degradation of particularistic productive attributes developed on the job, coupled with expansion of the requirements of formal education to produce its more *universal* dimensions. The latter is the necessary prerequisite for the constitution of the more general and abstract knowledge that the contemporary operator of computer-based technologies sets into motion vis-à-vis the 'Fordist' machinist ('controlling' that a task is automatically done correctly rather than actually 'doing' it). See Balconi 2002.

> ical power by the working class, technological education, both theoretical and practical, will take its proper place in the schools of the workers.[104]

Now, the question immediately arises as to what are the more concrete determinations behind this inevitability of the proletarian conquest of political power? Unfortunately, Marx provides no answer in these pages. In fact, one could argue that no answer could have been provided at all. The unfolding of the necessity of 'proletarian dictatorship' as a concrete social form involves still more mediations and, therefore, the former is not carried by the social form we are facing at this point of the exposition in the form of an *immediate potentiality* to be realised through the political action of the workers as a class.[105] Thus, at this stage of the dialectical presentation, both this latter remark and the one discussed above regarding the totally developed individual as the basis for the abolition of capital cannot but be unmediated observations, external to the concrete determinations of the productive subjectivity of large-scale industry that we have before us. On the other hand, inasmuch as the latter *does* involve *a certain degree* of universality, a limited, albeit real, expression of the underlying tendency for the production of its fully developed shape, Marx's reflections, although external, are undoubtedly pertinent. From a methodological point of view, he could therefore legitimately introduce those remarks in order to anticipate the direction that the further unfolding of this historically specific contradiction of the capitalist mode of production – 'the only historical way in which it can be dissolved and then reconstructed on a new basis' –[106] should take. But as a proper, complete dialectical account of the determinations underlying the proletarian conquest of political power or, above all, of the revolutionary production of the free association of individuals, the presentation as so far developed definitely falls short.[107]

---

[104] Marx 1976g, p. 619.

[105] This would need the exposition of the tendency for the concentration and centralisation of capital as the alienated expressions of the socialisation of labour in the capitalist mode of production and whose absolute limit is reached when the total capital of society immediately exists as a single capital (Marx 1976g, p. 779).

[106] Marx 1976g, p. 619.

[107] In the same vein, Marx's comments on capital's *raison d'être* in the chapter on simple co-operation also bear this twofold mark of externality and pertinence. The former because, unlike the condensed recapitulation of the general movement in the chapter on the 'Historical Tendency of Capitalist Accumulation', the totality of the determinations behind the realisation of that world-historical role is not yet there. The latter because, as I have pointed out earlier in my argument, that certainly *is* the first time in the presentation that

This, in itself, should not be problematic. From the perspective of the dialectical investigation as such, this juncture of this critical reading of Marx's search for the determinations of revolutionary subjectivity is not a dead-end at all. It only means that the journey from the abstract to the concrete needs to proceed forward as our end-point – namely, revolutionary subjectivity – still lies ahead. In this sense, no anomaly lies before us. However, the question is very different when approached from the standpoint of the elements for such an investigation we can find already objectified in Marx's *Capital*. In that respect, the problem that the contemporary reader of *Capital* attempting to discover those determinations faces is, to put it briefly, that *they are not there*. Let us expand on this point.

We have seen how Marx, when faced with the tendential universality of the worker of large-scale industry and the growing conscious regulation of social labour it entails, *extrinsically* reflects upon the specific material form of productive subjectivity necessary to 'build society anew' on a really free basis. On the other hand, we have highlighted the methodological pertinence of such a reflection given that – as the passage on 'really free working' from the *Grundrisse* quoted above stated – the latter itself has as one of its determinations that of being a bearer of universal productive attributes, that is, capable of 'material production of a general character'. So far so good. But, as the reader will remember, the attribute of universality did not exhaust the determinations of the form of *productive* subjectivity with the immediate potentiality for 'really free working' (which, as I argued, should provide the material foundation of revolutionary *political* subjectivity). In the first place, the latter also entailed a process of material production whose general social character was immediately posited. This condition is present – at least tendentially – in the productive subjectivity of large-scale industry as developed in *Capital* too.[108] But, in addition, note that Marx's passage from the *Grundrisse* mentions that the uni-

---

one can grasp an initial manifestation of the historical powers of private labour to take concrete form in their opposite: consciously organised, directly collective labour.

[108] In the chapter on 'Machinery and Large-Scale Industry', the tendency to expand the scope of the conscious regulation of the social character of labour coexists with an opposite tendency to multiply the number of privately mediated branches of the social division of labour, which is also the product of the movement of this form of production of relative surplus value (Marx 1976g, p. 572). But no reason is given for one or the other tendency to prevail. This occurs later in Marx's presentation, when he unfolds the determinations of the 'General Law of Capitalist Accumulation'. There, the tendencies to the concentration and centralisation of capital show how the first tendency eventually imposes itself over the second.

versality of 'revolutionary' productive subjectivity must be the expression of a *scientific* consciousness, capable of organising work as 'an activity regulating all the forces of nature'. And herein lies the crux of the matter.

Although the productive subjectivity of the worker of large-scale industry as presented in *Capital* tends to become universal, this universality is the product not of the *scientific expansion* of her/his capacity consciously to regulate the production process, but of the increasing (eventually absolute) *deprivation* of all knowledge of the social and material determinations of the labour process of which she/he is part. As we have seen above, for the workers engaged in the direct process of production, the separation of intellectual and manual labour reaches its plenitude. This kind of labourer can certainly work in any automated labour process which capital puts before her/him, but not as the 'dominant subject' with 'the mechanical automaton as the object'. Rather, for those workers 'the automaton itself is the subject, and the workers are merely conscious organs, co-ordinated with the unconscious organs of the automaton, and together with the latter, subordinated to the central moving force'.[109] The scientific productive powers needed to regulate the forces of nature, and which are presupposed to their objectified existence in a system of machinery, are not an attribute that capital puts into the hands (or, rather, in the heads) of direct labourers. In brief, in the figure of this wage labourer bearing what, following Iñigo Carrera,[110] I term an absolutely *degraded productive subjectivity*, scientific consciousness and universality do not go together, but are in opposition to one another. In other words, it is not this degraded productive subjectivity that, simply as such, carries in its immediacy the historical revolutionary powers that Marx himself considered necessary to make capital 'blow sky high'. Moreover, neither has Marx's exposition demonstrated that the very movement of the present-day alienated general social relation – capital accumulation – leads to the social necessity to transform, in the political form of a revolution, the productive subjectivity of those labourers in the direction of their reappropriation of the powers of scientific knowledge developed in this alienated form.

Yet, despite this insufficiency as an account of the material genesis of the revolutionary subject, it is here that Marx's exposition in *Capital* about the determinations of human productive subjectivity as an alienated attribute of the product of labour comes to a halt.[111] In the rest of Volume I (and the two remaining volumes), Marx no longer advances, in any systematic manner, in the unfolding of the material and social determinations of the revolutionary subject. From the point of the presentation reached, and after moving to the exteriority of the inner determinations of the production of surplus value and to its reproduction, accumulation and the general law that presides over its movement, he just makes a gigantic leap into the conclusion contained in the chapter on the 'Historical Tendency of Capitalist Accumulation', where Marx offers the following well-known account of the determinations leading to the abolition of the capitalist mode of production.

---

[109] Marx 1976g, pp. 544–5.

[110] Iñigo Carrera 2008.

[111] This statement needs qualification insofar as the creation of a surplus population relative to the needs of the accumulation process also constitutes a transformation of productive

> Along with the constant decrease in the number of capitalist magnates, who usurp and monopolize all the advantages of this process of transformation, the mass of misery, oppression, slavery, degradation and exploitation grows; but with this there also grows the revolt of the working class, a class constantly increasing in numbers, and trained, united and organized by the very mechanism of the capitalist process of production. The monopoly of capital becomes a fetter upon the mode of production which has flourished alongside and under it. The centralization of the means of production and the socialization of labour reach a point at which they become incompatible with their capitalist integument. The integument is burst asunder. The knell of capitalist private property sounds. The expropriators are expropriated.

If we leave aside the question of the misleading conflation between two *qualitatively different* (and, therefore, *analytically separable*) 'moments' of the revolutionary action of the working class contained in this passage – namely, the expropriation of the bourgeoisie and the abolition of capital[112] – the question remains as to whether the determinations developed by Marx in the previous chapters suffice to justify the transition to this excessively simplistic and all too general account of the way 'the capitalist integument is burst asunder'.[113] Certainly, the tendency to the centralisation of capital discussed in the chapter on the 'General Law of Capital Accumulation' does provide an exposition of the necessity behind the progressive socialisation of labour as an attribute of the capitalist form of private labour. But such an account stops short at the exter-

---

subjectivity produced by the development of large-scale industry. More concretely, it represents the most extreme case of material mutilation of the productive attributes of the working class, that is, not simply their degradation but their outright non-reproduction.

[112] I return to this fundamental point in the concluding remarks developed after the present chapter.

[113] Marx 1976g, p. 929.

iority of the *quantitative determination* of the scope of consciously organised social labour without saying anything about the *qualitative transformations* of the productive subjectivity of the collective labourer that such an extension of the scale of the former presupposes. Seen from that perspective, I think that the transition to revolutionary subjectivity contained in the passage is definitely unmediated.[114] How are those workers whose productive subjectivity has been emptied of almost all content to organise the allocation of the total labour power of society in the form of a *self-conscious* collective potency (the latter being what the abolition of capital is all about)? The growing 'misery, degradation, oppression and so on' certainly confront those labourers with particularly extreme *immediate* manifestations of the alienated mode of existence of their social being. Therefore, they could lead them to reinforce their collective resistance to capitalist exploitation by strengthening their relations of solidarity in the struggle over the value of labour power. In themselves, however, those expressions of capitalist alienation have no way of transforming the class struggle from a form of the reproduction of that alienation into the form of its fully self-conscious transcendence. From a materialist perspective, the question does not boil down to the will to radically transform the world, but to the objective existence of the material powers to do so. As Marx puts it in *The Holy Family*, it is about an 'absolutely imperative *need*' determined as 'the practical expression of *necessity*'.[115] The emergence of the social necessity underlying the historical constitution of those revolutionary transformative powers involves the mediation of more revolutions in the materiality of the productive subjectivity of workers.[116]

---

[114] This weakness in Marx's argument in *Capital* has been perceptively noted by Wendling 2009, p. 168.

[115] Marx and Engels 1975, p. 37.

[116] The above-cited passage from Chapter 32 of Volume I of *Capital*, if arbitrarily taken out of its systematic methodological context, can certainly lead to the most mechanistic of accounts of revolutionary subjectivity, very easy to codify into a dogma. See, for instance, Kautsky 1936. The point is that the whole content of the chapter on the 'Historical Tendency of Capital Accumulation' merely *summarises* the general movement that Marx has been systematically unfolding *throughout the whole of Volume I and, in particular, in the chapters on relative surplus value and the general law of capitalist accumulation*. When seen in this light, it is obvious that the development of the determinations of revolutionary subjectivity is a very complex (i.e. mediated) one indeed. The mechanistic misreading of that chapter is not restricted to traditional orthodox perspectives. It can also be found in critical interpretations of Marx's *Capital*, albeit in order to take issue with its content. Thus, in his *Introduction to the Three Volumes of Capital*, Heinrich maintains that in that passage: 'Marx drew conclusions amounting to a sort of historical determinism that *are not*

In this sense, I concur in general with those who claim that Marx's *Capital* is *incomplete*. However, not in the sense that the dialectic of capital needs to be complemented with that of class struggle,[117] or with the political economy of wage labour,[118] as if those latter aspects were not an inner moment of the former itself. Rather, I think that it is the very 'dialectic of capital', and, more concretely, the contradictory movement of the production of relative surplus value through the system of machinery, that is in need of completion. Without this further exploration into the development of human productive subjectivity as an alienated attribute of social capital, a gap is bound to remain between the 'dialectic of human labour' unfolded in the relevant chapters of *Capital* and the revolutionary conclusions at the end of Volume I.

In the following section, I shall examine Marx's presentation of the determinations of the system of machinery in the *Grundrisse*. Although the complete *systematic* unfolding of the missing determinations is not there either, the main *elements* for such a further investigation of revolutionary subjectivity can be extracted from that text.

The *Grundrisse* and the System of Machinery: In Search of the Missing Link in the Determinations of Revolutionary Subjectivity

As an entry point to Marx's account of the system of machinery in the *Grundrisse*, let us return for a moment to the examination of the determinations of large-scale industry as presented in *Capital*. More concretely, let us go back to the relation between science and the production process. Although this form of production of relative surplus value entailed the general application of science as a productive force, the latter was not an attribute materially borne by those

---

justified by his categorical depiction. To that extent, the passage is more an expression of hope than analysis; revolutionary enthusiasm triumphed over the cool scholar' (Heinrich 2012, p. 198, my emphasis). By contrast, my claim is that Marx's conclusions are not simply *without justification* in his systematic development. The problem is that their ground is not *fully* unfolded. It is, however, possible (and indeed necessary) to complete the systematic development which those revolutionary conclusions presuppose. But this is not what Heinrich has in mind. For him, revolutionary subjectivity has no immanent determinations or necessity that need to be reproduced by means of dialectical thought. It therefore falls outside the systematic 'depiction of the capitalist mode of production', which 'itself is not dependent upon these questionable conclusions' (Heinrich 2012, p. 198).

[117] Shortall 1994.

[118] Lebowitz 2003.

labourers engaged in direct labour in the immediate process of production. For them, that scientific knowledge took the form of an alien power already objectified in the machine. Marx notes this in the *Grundrisse* as well.

> The worker's activity, reduced to a mere abstraction of activity, is determined and regulated on all sides by the movement of the machinery, and not the opposite. The science which compels the inanimate limbs of the machinery, by their construction, to act purposefully, as an automaton, does not exist in the worker's consciousness, but rather acts upon him through the machine as an alien power, as the power of the machine itself.[119]

Yet, as Marx puts it in the *Results of the Immediate Production Process*, those scientific powers ultimately are themselves the products of labour.[120] Thus, although the *formal* subject of those powers – as happens with all the powers springing from the direct organisation of human co-operation – remains capital, the question immediately arises as to who is the *material* subject whose (alienated) *intellectual* labour develops the scientific capacities of the human species and organises their practical application in the immediate process of production. Having discarded manual labourers as such a productive subject, it would seem that the only alternative must be to turn our attention to the remaining character present in the direct production process, namely, the capitalist. Is it she/he who personifies, through the development of her/his productive consciousness and will, capital's need for the powers to scientifically control the movement of natural forces? The answer is given by Marx in a footnote to the chapter on 'Machinery and Large-Scale Industry' in *Capital*:

> Science, generally speaking, costs the capitalist nothing, a fact that by no means prevents him from exploiting it. 'Alien' science is incorporated by capital just as 'alien' labour is. But 'capitalist' appropriation and 'personal' appropriation, whether of science or of material wealth, are totally different things. Dr. Ure himself deplores the gross ignorance of mechanical science which exists among his beloved machinery-exploiting manufacturers, and Liebig can tell us about the astounding ignorance of chemistry displayed by English chemical manufacturers.[121]

---

[119] Marx 1993, p. 693.

[120] Marx 1976c, p. 1055.

[121] Marx 1976g, p. 508.

Thus, it is not the capitalist who embodies the intellectual powers to develop the scientific knowledge presupposed by its objectified existence in a system of machinery. The science incorporated in the immediate production process is the result of the appropriation of the product of the intellectual labour of an 'other'. This 'other', whose productive activity the direct production process of large-scale industry carries as a necessary mediation, is not explicitly present in Marx's exposition in *Capital*. There might be two reasons for this exclusion. First, in Marx's time such a social subject was only beginning to develop. Secondly, and following from the previous point, Marx's presentation in *Capital* is restricted to the transformations suffered by the productive subjectivity of those workers remaining in the direct production process. However, what his whole discussion implicitly suggests is that among the transformations that large-scale industry brings about is the extension of material unity comprising its total labour process outside the boundaries of the 'factory walls'.[122] Hence, the direct process of production becomes just an aspect of a broader labour process which now entails two additional moments: the development of the power consciously to regulate in an objective and universal fashion the movement of natural forces – namely, science – and the application of that capacity in the practical organisation of the automatic system of machinery and whatever remains of direct labour – the technological application of science, including the consciousness of the unity of productive co-operation. Certainly, these other moments are also present in *Capital*.[123] However, Marx's presentation there seems to revolve around the emphasis on their separated mode of existence vis-à-vis the subjectivity of direct labourers and which is presupposed by their activity. By contrast, in the *Grundrisse* he oscillates between such an angle on the question,[124] and one which puts at the forefront the underlying material unity of the total activity of living labour, where the development of science and its technological applications act as essential constitutive moments.[125] With the system of machinery,

---

[122] In this examination of the further determinations of the production process of large-scale industry, I draw on Iñigo Carrera (2008, pp. 17–23).

[123] Marx 1976g, p. 549.

[124] Marx 1993, pp. 693–4.

[125] Dunayevskaya (1989, pp. 80–6) correctly notes the difference in presentation between the account of the system of machinery in the *Grundrisse* – where the emancipatory potentialities of the system of machinery are considered – and the one in *Capital* – where its determination as a materialised expression of the domination of dead over living labour is emphasised. However, she wrongly attributes that to a change in Marx's view on the subject, instead of as an account of *qualitatively different* potentialities engendered by the

> the entire production process appears as not subsumed under the direct skillfulness of the worker, but rather as the technological application of science. [It is,] hence, the tendency of capital to give production a scientific character; direct labour [is] reduced to a mere moment of this process.[126]

The determinations presupposed by the production of relative surplus value involve the specification of commodity owners into capitalist and wage labourer. Having discarded the former as the material subject of scientific labour, it is self-evident that only those determined as doubly free individuals can personify the development of this moment of the production process of large-scale industry. Thus, although not explicitly addressed by Marx, the benefit of historical hindsight makes it very easy for us to recognise how the total social capital deals with its constant need for the development of the productive powers of science, namely, by engendering a special partial organ of the collective labourer whose function is to advance in the conscious control of the movement of natural forces and its objectification in the form of ever more complex automatic systems of machinery. Whilst the system of machinery entails the progressive deskilling of those workers performing what remains of direct labour – to the point of emptying their labour of any content other than the mechanistic repetition of extremely simple tasks – it also entails the tendential *expansion* of the productive subjectivity of the members of the intellectual organ of the collective labourer. Capital requires from these workers ever more *complex* forms of labour.[127] As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker'. Needless to say, inasmuch as this expanded productive subjectivity is nothing more

---

very same development of the system of machinery and personified by the different partial organs of the collective labourer.

[126] Marx 1993, p. 699.

[127] Braverman's (1998) so-called 'deskilling' thesis is obviously a one-sided reduction of this *twofold* movement of degradation/expansion of the productive subjectivity of the collective labourer required by the system of machinery to one of its moments (Iñigo Carrera 2008, p. 44). One of the immediate reasons behind such a unilateral account lies, as Tony Smith points out, in its very restricted definition of 'skill', very much referring to *manufacturing* skills (Smith 2000, p. 39). An early in-depth critical examination of Braverman's thesis can be found in Elger (1979). In fact, one could argue that both 'Fordist' and 'Post-Fordist' methods involve both deskilling and the enhancement of workers' 'skills' (Tomaney 1994). On Fordism, see Clarke 1992. Clarke (1990) also demolishes the fantasies of most of the literature on 'Post-Fordism', laying bare its purely ideological character. On 'lean production' in particular, see the work of Tony Smith just referred to above.

than a concrete form of the production of relative surplus value, the exercise of the newly developed intellectual productive powers is inverted into a mode of existence of capital in its movement of self-valorisation as well.[128]

In this alienated form, capital thereby produces a material transformation whose fundamental significance exceeds the production of wage labourers simply bearing different productive attributes. At stake here, first and foremost, is a radical substantial transformation of the very nature of human labour.[129] The latter progressively ceases to consist in the direct application of labour power onto the object of labour with the purpose of changing its form. It now increasingly becomes an activity aimed at the conscious control of the movement of natural forces in order to make *them* automatically act upon the object of labour and, in this way, effect its change of form. According to Marx's exposition of the system of machinery in the *Grundrisse*, *it is in the contradictory historical unfolding of this specific material transformation of human productive subjectivity that the key to the absolute limit to capital resides*.

> To the degree that labour time – the mere quantity of labour – is posited by capital as the sole determinant element, to that degree does direct labour and its quantity disappear as the determinant principle of production – of the creation of use values – and is reduced both quantitatively, to a smaller proportion, and qualitatively, as an, of course, indispensable but subordinate moment, compared to general scientific labour, technological application of natural sciences, on one side, and to the general productive force arising from social combination [*Gliederung*] in total production on the other side – a combination which appears as a natural fruit of social labour (although it is a historic product). *Capital thus works towards its own dissolution as the form dominating production*.[130]

To put it briefly, the issue here is the old question of the relation between intellectual and manual labour.[131] More concretely, the fundamental point to grasp is the specifically capitalist form in which the antithetical movement of those two moments of living labour asserts itself with the development of the system of machinery. The revolutionary aspect of this historically specific transformation of living labour in capitalist society is that both the scale and complexity of the production process and, in particular, the increasingly scientific character of its organisation, make the subjectivity of the capitalist (the non-labourer) incapable of personifying the now directly social labour under the rule of her/his capital. This means, in other words, that the development of the powers of intellectual labour and their exercise becomes an attribute of the 'labouring classes'. As Marx states in the *Theories of Surplus-Value*:

---

[128] That is, the productive powers of science take an alienated form not just vis-à-vis manual labourers, who face them already objectified in the system of machinery. Intellectual labourers also confront the development of science, which they themselves personify, as an alien power borne by the product of their social labour. Moreover, the alienated nature of this development of intellectual labour is even expressed in its general scientific form, that is, in its method. I return to this question in the concluding remarks below.

[129] Iñigo Carrera 2008, p. 20.

[130] Marx 1993, p. 700, my emphasis.

[131] Sohn-Rethel's *Intellectual and Manual Labour* (1978) has become a *locus classicus* on this

> *Concentration of capital* … It is in this extreme form of the contradiction and conflict that production – even though in alienated form – is transformed into social production … As *functionaries* of the process which at the same time accelerates this *social* production and thereby also the development of the productive forces, the capitalists become superfluous in the measure that they, on behalf of society, enjoy the usufruct and that they become overbearing as *owners* of this social wealth and *commanders* of social labour. Their position is similar to that of the feudal lords whose exactions in the measure that their *services* became superfluous with the

---

question. It certainly provides a good starting point, especially concerning the historicity of the forms of scientific thought. However, his idiosyncratic approach is not exempt from shortcomings. For a critical assessment of Sohn-Rethel's work, see Kapferer 1980; Bahr 1980; Reinfelder and Slater 1978. The main shortcoming of Sohn-Rethel's book, correctly highlighted by these critical appraisals, is its ambiguity on the question of the capital-determined nature of the very materiality of technological forms and the forms of science presupposed by them. In effect, despite all his emphasis on the historicity of what I have termed 'representational scientific thought', Sohn-Rethel actually attributes the latter full objective validity, albeit with 'false consciousness', meaning a lack of awareness of its own social existence and historical genesis (Kapferer 1980, p. 81). The transcendence of the capitalist mode of production therefore does not actually involve the transformation of the very forms of scientific knowledge and technology; only liberation from their blindness to their own social determinations as an inner moment of human labour. This is the result of the reunification of intellectual and manual labour. But if Sohn-Rethel ultimately failed to grasp the inherently capitalist nature of the very structure of modern science and technology, the critics referred to above fail to see the necessity of the transcendence of those forms of scientific thought as an immanent potentiality engendered by the historical movement of the capital form itself, albeit one which expresses the necessity of its own annihilation.

> rise of bourgeois society, became mere outdated and inappropriate privileges and who therefore rushed headlong to destruction.[132]

The scientifically expanded productive subjectivity of intellectual labour is, by its own nature, increasingly general or universal. The exertion of this form of human labour power aims at the expansion of the conscious control over the *totality* of the forces of nature. Moreover, this subordination of the latter to the powers of living labour involves the comprehension of their *general* determination in order thereby to develop their *particular* technological applications in ever-evolving systems of machinery. Thus, as Marx puts it in Volume III of *Capital* in order to highlight its specificity vis-à-vis co-operative labour, scientific labour is, by definition, universal labour.[133]

With the constitution and permanent revolutionising of this organ of the collective labourer, capital thereby engenders *another* tendency for the production of workers bearing a universal productive subjectivity.[134] However, this universality is no longer the *empty* universality deriving from the absolute *lack* of individual productive capacities to which direct labourers are condemned. When developed into its plenitude, it becomes the rich, concrete universality of organs of a collective subject who become increasingly able to consciously rule their life process by virtue of their capacity scientifically to organise the production process of any automatic system of machinery and, therefore, any form of social co-operation on the basis of large-scale industry. As the productive subjectivity of workers expands, it progressively ceases to be the case that the worker's individuality vanishes 'as an infinitesimal quantity in the face of the science, the gigantic natural forces, and the mass of social labour embodied in the system of machinery'.[135] For the latter *are* the direct products of the objectification of their productive subjectivity.

---

[132] Marx 1989b, p. 449.

[133] Marx 1991, p. 199.

[134] A remarkable weakness of Postone's (1996) otherwise interesting discussion of real subsumption lies in his implicit reduction of the working class of large-scale industry to direct manual labourers. Clearly, the *formal subject* of the development of science and technology is capital, as happens with all the productive powers of social labour springing from the direct co-operation of workers. However, the development of those productive powers has no *material subject* in Postone's account. That is one of the reasons why he cannot see that the potentiality for the abolition of capital is actually borne by the proletariat.

[135] Marx 1976g, p. 549.

> Nature builds no machines, no locomotives, railways, electric telegraphs, self-acting mules etc. These are products of human industry; natural material transformed into organs of the human will over nature, or of human participation in nature. They are *organs of the human brain, created by the human hand*; the power of knowledge, objectified. The development of fixed capital indicates to what degree general social knowledge has become a *direct force of production*, and to what degree, hence, the conditions of the process of social life itself have come under the control of the general intellect and been transformed in accordance with it. To what degree the powers of social production have been produced, not only in the form of knowledge, but also as immediate organs of social practice, of the real life process.[136]

We saw how in *Capital* Marx focused on the 'negative side' of the effects of production of relative surplus value through the system of machinery upon the material forms of the productive subjectivity of the working class. The historical emergence of the social necessity for the constitution of a 'fully-developed social individual' thus appeared as an abstract possibility, whose connection to capital's development of machine-based production seemed to be completely external. Conversely, we can appreciate now how in the *Grundrisse* Marx posits capital's relentless tendency to 'call to life all the powers of science and of nature, as of social combination and of social intercourse'[137] as necessarily engendering the historical becoming of that concrete universal subjectivity itself.

> No longer does the worker insert a modified natural thing [*Naturgegenstand*] as middle link between the object [*Objekt*] and himself; rather, he inserts the process of nature, transformed into an industrial process, as a means between himself and inorganic nature, mastering it. He steps to the side of the production process instead of being its chief actor. In this transformation, it is neither the direct human labour he himself performs, nor the time during which he works, but rather the appropriation of his own general productive power, his understanding of nature and his mastery over it by virtue of his presence as a social body – it is, in a word, the development of the social individual which appears as the great foundation-stone of production and of wealth.[138]

---

[136] Marx 1993, p. 706.

[137] Ibid.

[138] Marx 1993, p. 705.

Moreover, and here in accordance with *Capital*, he presents the latter as the one whose further expansion eventually clashes with its alienated capitalist social form and, therefore, as the material form of productive subjectivity that carries as an immediate potentiality the necessity for the 'creation of the new society'. Hence, Marx continues,

> The *theft of alien labour time, on which the present wealth is based*, appears a miserable foundation in face of this new one, created by large-scale industry itself … The *surplus labour of the mass* has ceased to be the condition for the development of general wealth, just as the *non-labour of the few*, for the development of the general powers of the human head. With that, production based on exchange value breaks down, and the direct, material production process is stripped of the form of penury and antithesis.[139]

It might seem that Marx is here substituting the intellectual labourer for the manual labourer as the revolutionary subject. However, the point is that the key consists not in abstractly opposing intellectual and direct manual labour in order to privilege one over the other, but rather in grasping the contradictory forms in which capital historically develops these two necessary moments of the labour process. Since Marx's exposition in the *Grundrisse* is only concerned with the *general* tendency and, more specifically, its historical result – that is, with the movement of 'bourgeois society in the long view and as a whole'[140] – he does not pay much attention to the contradictory forms in which the latter asserts itself. However, it is clear that in the historical unfolding of the tendency for the progressive objectification of all direct application of human labour power onto the object of labour as an attribute of the machine, capital actually *reproduces and exacerbates* the separation between intellectual and manual labour.[141]

---

[139] Marx 1993, pp. 705–6.

[140] Marx 1993, p. 712.

[141] One of the central weaknesses of recent theories of 'immaterial labour' or 'cognitive capitalism', which heavily rely on the 'Fragment on Machines', is their 'stagist' reading of that text. See, for example, Virno 2007; Lazzarato 1996; Vercellone 2007. In other words, those authors use those passages from the *Grundrisse* for a formalistic specification of a qualitatively different stage of capitalist development that is said to supersede not only large-scale industry, but also real subsumption: the epoch of the 'general intellect'. Worse still, those theories unmediatedly – hence speculatively – apply the essential tendency and finished form described in the *Grundrisse* onto contemporary concrete

In effect, inasmuch as capital's conversion of the subjective expertise of the direct labourer (both intellectual and manual) into an objective power of the machine is not an instantaneous event, but rather is done by degrees, every leap forward in the abolition of manual labour brought about by the revolution in the material forms of the process of production is realised by actually multiplying the spaces for the exploitation of manual living labour. In fact, the new technological forms themselves might generate as their own condition of existence the proliferation of a multitude of production processes still subject to the manual intervention of the labourer, whether as an appendage of the machine, as a partial organ in a manufacturing division of labour or even in the form of 'domestic industry'. Thus, until the conditions for the (nearly) total elimination of manual labour are produced, direct labour as an appendage of the machine and/or the division of labour of manufacture tend to be reproduced under the new conditions and with even more degraded forms of productive subjectivity and harsher conditions of capitalist exploitation.[142]

---

forms of realisation that still represent its negation (Starosta 2012). The result is that they overlook or downplay the contradictory movement of expansion/degradation and universalisation/particularisation entailed by current material forms of real subsumption. As we have seen, what the 'Fragment on Machines' unfolds is not the abstract opposite of the determinations of the productive subjectivity of large-scale industry, but rather their more concrete development. The significance of that undoubtedly essential text is therefore *systematic*. And, incidentally, so is that of the distinction between the three different forms of real subsumption presented in *Capital* and that between formal and real subsumption. For a forceful case against the 'stagist' reading of those chapters of *Capital*, see Tomba 2007 and 2013.

[142] This is illustrated by Marx in section 8 of the chapter on 'Machinery and Large-scale Industry' in *Capital*. See Marx 1976g, pp. 588–610. There he shows how the production of relative surplus value through the system of machinery reproduces modern manufacture, handicrafts and domestic industry. In this way, capital revolutionises the determinations of the social existence of not only those workers incorporated into large-scale industry, but also those of the sections of the working class still working under the division of labour in manufacture or domestic industry. The latter forms of the social production process persist in their survival only through the imposition of the most brutal forms of the exploitation of the workers. However, Marx makes clear that the subsistence of manufacture and domestic industry is always provisional, even if it appears to hang on for long periods of time. The general tendency of capital is for the total development of large-scale industry. Moreover, Marx's discussion makes clear that the working class does not have to 'sit and wait' until the limit for the subsistence of manufacture is reached – a limit given by the extent to which the overexploitation of labour power compensates for its relative lower productivity of labour vis-à-vis large-scale industry. Inasmuch as the struggle for the shortening of the working day succeeds in forcing its implementation in

Yet it is certainly the case that this internal differentiation of the collective labourer on the basis of the respective forms of productive subjectivity is the self-negating form in which the *abolition* of that separation is realised in the historical process. Thus, through the very exacerbation of their separation, capital tendentially abolishes the qualitative and quantitative weight of manual labour in the process of reproduction of social life, thereby converting the essential moment of living labour into an intellectual process. In this way, capital's transformation of the labour process eventually reaches a point at which the separation between intellectual labour and what is now a quantitatively and qualitatively insignificant amount of manual labour cannot materially obtain as a form of organising the life process of humanity. The development of the material productive forces of society can only assert itself through the embodiment of the intellectual powers of social production in the individual subjectivity of every partial organ of the now directly social productive body. Moreover, this incorporation of the powers of the 'general intellect' into every individual worker must now have the form of objective social knowledge – namely, science – rather than being the product of the immediate subjective productive experience of the labourer (as was the case of independent handicraft production). As we shall see below, it is the consciously organised political action of the *whole* working class – whatever its productive subjectivity – that is the necessary form in which this latter material transformation is realised.[143]

---

the branches of production where manufacture persists, it accelerates the development of large-scale industry by not allowing the selling of labour power below its value and, therefore, by reducing the capitalist limit to the introduction of machinery. Here we have a clear instance of the way in which progressive politics mediates revolutionary politics, the former being the concrete form of the development of the material determinations for the emergence of the latter.

[143] Besides, it goes without saying that although the workers bearing an expanded productive subjectivity express the *movement towards* the development of an all-sided universal individuality, they do so within the limits of capital as an alienated social form. In other words, it is not the *immediacy* of the material forms of their productive subjectivity that constitutes the kind of 'rich and all-sided individuality' discussed by Marx (1993, p. 325). As much as workers with a degraded productive subjectivity, they have to not only change 'society', but also undergo a process of self-change in the course of the revolutionary process. Hence, *both* organs of the collective labourer have to 'get rid of the muck of ages' imposed by the determination of human subjectivity as a concrete form of the production of relative surplus value. More concretely, this entails the *transformation* of intellectual labour (i.e. in the mode of scientific cognition or the kind of scientific method) and its *generalisation* to all members of the collective productive body.

In its formally boundless movement of self-valorisation, capital therefore cannot stop in the historical production of universal productive subjects. At the same time, this constant revolution in the material forms of human productive subjectivity can only take place through the progressive socialisation of private labour, thereby positing the extension of the scope of the conscious regulation of directly social labour as an immediate necessity for capital's production of relative surplus value. Thus, through the development of large-scale industry, capital works towards the historical emergence of the other precondition for 'really free working' as well.

> In the production process of large-scale industry … just as the conquest of the forces of nature by the social intellect is the precondition of the productive power of the means of labour as developed into the automatic process, on one side, so, on the other, is the labour of the individual in its direct presence posited as suspended individual, i.e. as social, labour. Thus the other basis of this *mode of production falls away*.[144]

On the twofold basis of the expansion of the scientific productive powers of the 'general intellect' and of the determination of human labour as directly social, capital moves tendentially towards reaching its absolute historical limit as a social form. This limit is not reached when capital accumulation *ceases* to develop the material productive forces of society as, following Trotsky,[145] orthodox Marxists would have it. On the contrary, capital clashes with its limit when the very same alienated socialisation and scientific universalisation of the powers of human labour through the production of relative surplus value begets, *as its own immanent necessity*, the development of the productive forces of society in a particular material form, namely, the fully conscious organisation of social labour as the *general* social relation regulating the reproduction of human life and, therefore, as an attribute borne by every singular productive subjectivity comprising the collective labourer. Under those circumstances, the further leap forward in the material productive forces of society – dictated by the most immediate necessity of capital itself, that is, the production of relative surplus value – comes into conflict with capitalist relations of production. Translated into our mode of expression, this classical Marxian insight can only mean the following: the *alienated* social necessity arises for the human being to be produced as a productive subject that is fully and objectively conscious of the social determinations of her/his individual powers and activity. Thus, she/he no longer sees society as an alien and hostile power that dominates her/him. Instead, he/she consciously experiences the materiality of social life (that is, productive co-operation) as the necessary condition for the development of the plenitude of his/her individuality, and therefore consciously recognises the social necessity of the expenditure of her/his labour power in organic association with the other producers. However, this form of human subjectivity necessarily collides with a social form (capital) that produces human beings as *private and independent individuals* who consequently see their general social interdependence and its historical development as an alien and hostile power borne by the product of social labour. The determination of the material forms of the labour process as bearers of objectified social relations can no longer mediate the reproduction of human life. *Capital accumulation must therefore come to an end and give way to the free association of individuals*.

---

[144] Marx 1993, p. 709.

[145] Trotsky 1938, pp. 1–2.

> But with the suspension of the *immediate* character of living labour, as merely *individual*, or as general merely internally or merely externally, with the positing of the activity of individuals as immediately general or *social* activity, the objective moments of production are stripped of this form of alienation; they are thereby posited as property, as the organic social body within which the individuals reproduce themselves as individuals, but as social individuals. The conditions which allow them to exist in this way in the reproduction of their life, in their productive life's process, have been posited only by the historic economic process itself; both the objective and the subjective conditions, which are only the two distinct forms of the same conditions.[146]

In brief, capital exhausts its *raison d'être* in the historical process, thereby producing the social necessity for its abolition and, at the same time, revealing the material content pushing forward in that alienated form: *the self-production of the human individual as a working subject or the historical development of human productive subjectivity*.

> As the system of bourgeois economy has developed for us only by degrees, so too its negation, which is its ultimate result. We are still concerned now with the direct production process. When we consider bourgeois society in the long view and as a whole, then the final result of the process

---

[146] Marx 1993, p. 832.

> of social production always appears as the society itself, i.e. the human being itself in its social relations. Everything that has a fixed form, such as the product etc., appears as merely a moment, a vanishing moment, in this movement. The direct production process itself here appears only as a moment. The conditions and objectifications of the process are themselves equally moments of it, and its only subjects are the individuals, but individuals in mutual relationships, which they equally reproduce and produce anew. The constant process of their own movement, in which they renew themselves even as they renew the world of wealth they create.[147]

It is possible to appreciate now the significance of the 'Fragment on Machines' from the *Grundrisse* for the completion of the dialectical exposition of the productive subjectivity of large-scale industry. Although clearly in an unsystematic fashion (after all, they are only research manuscripts), that earlier version of the critique of political economy contains the elements for the systematic unfolding of the plenitude of the determinations that constitute the immanent potentiality of capital-transcending transformative practice that *Capital* only partially achieves. These further mediations are crucial for the concretisation of that which in *Capital* appeared as an abstract possibility: the emergence of the historical and social necessity underlying the abolition of capital.

Yet the exposition in the *Grundrisse* itself seems to be incomplete too, although for exactly the opposite reasons behind the incompleteness of Marx's discussion in *Capital*. Whereas in the latter text it is the unfolding of the material determinations of the *productive* subjectivity of large-scale industry which is in need of completion, in the *1857–8 Manuscripts* it is the part played by the *political* subjectivity of wage workers in the abolition of capital that is in need of clarification. If anything, the political action of the proletariat is noticeable for its *absence* in Marx's account of the dissolution of the capitalist mode of production in the *Grundrisse*. As Rovatti points out, the 'Fragment on Machines' is perfectly compatible with a fatalist, objectivist or mechanical conception of the abolition of capital, which posits its necessity in an external relation with the revolutionary intervention of the proletariat.[148] Indeed, this is the reading that results when the account of the development of large-scale industry is grasped as the positing of abstractly objective conditions for revolutionary action, which would need to be complemented by equally abstract subjective ones (generally seen as grounded in the mere existence of labour power as a commodity, i.e. in the formal subsumption of labour to capital). However, I think that this is not a properly dialectical way of grasping what Marx is getting at in those passages of the *Grundrisse*.

---

[147] Marx 1993, p. 712.

[148] Rovatti 1973. Rovatti, however, can escape the objectivist reading only by falling into its abstract opposite, namely, subjectivism. The objectivist reading results when the contradiction immanent in the system of machinery is grasped in purely quantitative terms,

As I argued in Chapter 6, from the methodological perspective of science as practical criticism, the question is not one of investigating the objective circumstances constraining the affirmation of our freely self-determining action. Rather, it is a matter of apprehending in thought the *inner* material and social determinations of our radical transformation of the world. In other words, the question under investigation does not revolve around the discovery of the 'objective and subjective conditions' for the revolutionary transcendence of capital, but rather that of its *content and form*. Seen in this light, we can easily see what Marx's exposition in the 'Fragment on Machines' in the *Grundrisse* is all about: it unfolds the *content* of the social necessity for the abolition of the capitalist mode of production *without* specifying its *form*. By contrast, in *Capital*, Marx does establish, albeit by means of an insufficiently grounded exposition, the character of that necessary form, namely, the revolutionary political action of the whole working class. In their unity, the *Grundrisse* and *Capital* therefore provide the elements for the scientific exposition of the determinations of capital leading to the social constitution of the revolutionary proletariat.[149] What remains to be done is to flesh out more explicitly that immanent

---

rather than in terms of the qualitative determinations of productive subjectivity. That is, when focusing on how capital's reduction of necessary labour to a minimum leads to the impossibility of converting disposable time into surplus labour. Concomitantly, communism becomes reduced to a problem of overcoming scarcity or of the generalisation of abundance. Piccone (1975, p. 245), even if trying to go beyond the 'orthodox' reading of the *Grundrisse* offered by Nicolaus in the Foreword, shares that quantitative reading of the section on machines. Other objectivist readings focus on the alleged contradiction between the tendential disappearance of immediate labour in machine-based production and the determination of value as based on 'labour-time'. See Heinrich (2013) for a critique of this latter interpretation of the 'Fragment on Machines', which he nonetheless sees as correct as a *reading* of Marx's *Grundrisse*. His critical point is that Marx himself was wrong (or unclear) in that early version of the critique of political economy.

[149] Caffentzis's recent assessment of the 'Fragment on Machines' from *Grundrisse* vis-à-vis Marx's views in *Capital* precisely fails to uncover this necessary connection between content and form of the abolition of capital respectively contained in each of the two texts. For him, the *Grundrisse* and *Capital* contain 'two images of revolution', the earlier

connection between the content and form of the abolition of capital. In the following chapter, and by way of a conclusion, I offer some final reflections in order to establish that link. Additionally, bringing together the major insights found in the work of Iñigo Carrera, which has informed my reading of Marx, I develop some further considerations about determinations of revolutionary subjectivity which, I think, are also needed to complete the picture found in both *Capital* and the *Grundrisse*.

---

manuscript based on 'the external workings of the system driven by the introduction of science and technology', and the later version based on 'a working class that was inside the system, threatening to burst out of capital's desiccated skin' (Caffentzis 2013, p. 281).

CHAPTER 9

By Way of a Conclusion: Further Explorations into the Determinations of Revolutionary Subjectivity

Revolutionary Subjectivity as Alienated Subjectivity

In order to make explicit the *necessary* mediation between the content and form of the revolutionary abolition of capital, which is absent from the *Grundrisse*, we must bring back Marx's discussion of the role of the class struggle as presented in *Capital*. As we have seen, both through the discussion of the establishment of a legal working day and the Factory Acts, Marx unfolds the determination of the political action of the working class as the necessary mediation, in the form of a consciously organised collective action, for the imposition of the *general* conscious regulation of social labour in the capitalist mode of production, that is, as a concrete form of the essentially *unconscious* – hence inverted – organisation of social life through the capital form. Furthermore, we saw above that the struggle of wage labourers as a class was also the necessary form in which the total social capital's need for workers with an increasingly universal productive subjectivity, resulting from the movement of the *real* subsumption in the form of large-scale industry, asserted itself. True, in Marx's exposition in Chapter 15 of *Capital*, the class struggle does not transcend its determination as a mediating moment of the total social capital's reproduction. This is because he does not unfold its immanent material content – the socialisation and universal development of human productive subjectivity – up to its absolute limit. But this is precisely what the *Grundrisse* do; they do not unfold a *different* content, but rather develop a more complex shape of that content itself. *A fortiori*, its concrete mode of realisation remains the same: the struggle of wage labourers as a class. A struggle, however, that is no longer determined as form of capital's *reproduction*. As an expression of the plenitude of its content, the political action of wage labourers now becomes determined as the mode of existence of capital-*transcending* human practice.

In effect, I have shown that the material content of the communist transformation of social life precisely consists in the realisation of the plenitude of the two determinations underlying capital's historic mission, namely, the production of a fully developed universal productive subjectivity, which is in turn the necessary form of human *individuality* presupposed by the fully conscious organisation of *social* life as a directly collective process. Thus, as the material

subject whose productive subjectivity this historic process transforms 'behind its back' in the direction of a fully developed and socialised universality, the working class thereby becomes determined to personify, through its revolutionary political action, the *alienated* necessity of capital to be superseded in the free association of individuals or communism. Fundamental implications follow from this.

When discussing commodity fetishism, I mentioned that behind the traditional Marxist view rests the idea of revolutionary consciousness as the absolute opposite of alienated consciousness. In other words, revolutionary political action is seen as grounded in an abstractly free human subjectivity of the proletariat, which in that capital-transcending practice gets rid of objectified forms of social mediation that constrain the affirmation of their natural freedom. By contrast, what follows from the approach developed here is that revolutionary consciousness can only be a concrete form of the alienated consciousness itself. Let me elaborate on this.

In the first place, this means that the necessity for revolutionary transformation springs from the movement of self-valorising value itself. More concretely, it is a concrete determination of capital's incessant drive to produce relative surplus value. The crux of the matter is that it is a necessity of relative surplus value production, which can only take concrete shape through the abolition of the capital form (hence of surplus value production) itself. To put it differently, that particular cycle of material reproduction of society is *autonomously* set into motion by the valorisation of capital as its immanent purpose. However, the determinate form of the *material* transformation of the labour process – dictated by the most immediate necessity of capital to expand its magnitude – becomes the fully conscious organisation of human productive co-operation. Which, in turn, means that the *social* form of the life process of humanity must be revolutionised as well: it is a change of the materiality of the production process which, albeit required by the valorisation of capital, can no longer proceed on the basis of that alienated general social form.

Perhaps I can flesh out this point more clearly by discussing the following oft-quoted passage from *The Holy Family* in light of Marx's mature critique of political economy:

> Indeed private property drives itself in its economic movement towards its own dissolution, but only through a development which does not depend on it, which is unconscious and which takes place against the will of private property by the very nature of things, only inasmuch as it produces the proletariat as proletariat, poverty which is conscious of its spiritual and physical poverty, dehumanization which is conscious of its

> dehumanization, and therefore self-abolishing … Not in vain does it [the proletariat] go through the stern but steeling school of *labour*. It is not a question of what this or that proletarian, or even the whole proletariat, at the moment *regards* as its aim. It is a question of *what the proletariat is*, and what, in accordance with this *being*, it will historically be compelled to do.[1]

In this passage, Marx still seems to be within the boundaries of the kind of argument developed in the *Paris Manuscripts*, where revolutionary subjectivity seems to be grounded in a generic dialectic of the negation of the negation. Thus, in the proletariat all the inhumanity of private property is concentrated. Therefore, as that human incarnation of the complete negation of humanity, they are bound to revolt against those inhuman conditions. In turn, this revolt against inhuman conditions of life cannot but represent its negation and, therefore, the affirmation of humanity. It is this aspect which is generally emphasised within Marxism. Yet as my discussion of the limitations of that approach should make evident, one must focus elsewhere. The key points are as follows.

First, it is crucial to note how Marx uses the term 'compelled' to refer to the relation of the workers to their own revolutionary activity. I think this shows that for Marx the alienated subject of that historical movement culminating in (hence including) the revolution is capital itself (what he refers to as 'private property'). In this sense, the revolutionary powers are not 'self-developed' by the workers, but are an alienated attribute that capital puts into their own hands through the transformations of their productive subjectivity produced by the alienated socialisation of private labour. This is the reason why *revolutionary consciousness is itself a concrete form of the alienation of human powers as capital's powers*. The abolition of capital is not an abstractly free, self-determining political action, but one that the workers are *compelled* to undertake as *personifications* of the alienated laws of movement of capital itself. In this sense, when the workers consciously organise the revolutionary abolition of the capitalist mode of production, they do so not as the incarnation of the powers of an abstract human practice deprived of social determinations, but as 'character masks' or 'representatives' of the inverted existence of the powers of their social labour, i.e. capital. The point is that it is an alienated action that *in the course of its own development* liberates itself from all trace of its alienated existence. Paraphrasing that passage from the *1859 Contribution*, which I quoted toward the end of Chapter 6, individuals 'emerging from the reproduction process are accordingly different from those entering it'. They enter it as wage workers personifying capital's need to produce relative surplus value. Yet, in the course of the revolutionary action they undertake as such personifications, they 'change skin' and emerge as consciously (thus freely) associated fully developed social individuals.

---

[1] Marx and Engels 1975, pp. 36–7.

Secondly, this leads to the question of the specific *qualitative content* of revolutionary consciousness. This consciousness is not simply an extension of partial struggles based on the very same 'class identity' constituted around the affirmation of an abstract human freedom against the (apparently) external coercion imposed by the capital-determined modes of social objectivity. Revolutionary political action is such because of the *qualitative* potentiality it embodies, which resides in its being the form in which the fully conscious organisation of social life is historically produced. In this specific determination, *it has to be a fully conscious action itself*. Thus, it is a question not just of struggling against capitalist society as a 'totality', but also of the determinate form in which wage workers *consciously grasp*, as the way of organising that political action, their alienated general social relation. However general in its scope and fierce in its intensity, the political action of workers cannot be determined as revolutionary except when ideally reproducing capital in the totality of its social determinations. In other words, this essentially means that workers must comprehend the determinations of their own social being in their unity beyond any appearance presented by it. This does not only involve seeing through the transposed concrete forms of *objectivity* presented by the alienated consciousness in the capitalist mode of production, i.e. the value form and its concrete development into capital. In addition, it also entails discovering the content behind the most general concrete form of subjectivity assumed by the alienated consciousness of the modern individual, namely, the apparently natural self-determining freedom of the commodity owner. Thus, revolutionary workers must grasp the immanently alienated nature of their own subjectivity or their existence as attributes of the total social capital, which has become the concrete subject of modern society. But this also entails the discovery of the material productive powers that, as capital's mode of existence, they have developed in that inverted form. In this way, workers shall recognise the social necessity of the historical task that, as fully conscious yet *alienated* individuals, they have to personify through their self-abolishing political action, namely, the revolutionary supersession of capital through the production of the communist organisation of social life.

Revolutionary Subjectivity as Productive Subjectivity

In the traditional Marxist account of the revolutionary abolition of capital, the latter presupposes the development of two sets of clearly distinct necessary conditions: the 'objective' ones (generally associated with one aspect of the 'economic' laws of motion of capital such as its crisis-ridden character, the mechanical impossibility of economic reproduction, the tendency for the concentration and centralisation of capital, generalised barbaric conditions of human civilisation), and the 'subjective' ones (class consciousness and organisation). The whole history of Marxism could be reconstructed on the basis of the ways in which the different currents emphasised one or the other factor, or, alternatively, tried to combine the objective and subjective factors. But what unites most approaches, and, I think, what dooms their attempts at discovering the concrete determinations of revolutionary action to failure, is the complete independence they posit between the *political* consciousness of the working class and the development of the materiality of the production process of human life. Because even when the need for material conditions *is* emphasised, the problem is that the particular condition or set of conditions generally posited as *objectively* grounding the necessity for the abolition of capital (be it a fatal economic crisis or the monopolisation of the property of capital simply as such) has no connection whatsoever with the political subjectivity of the working class. The latter is seen as developing according to its own different 'logic', generally deriving from the determinations of the *formal* subsumption of labour to capital and therefore irrespective of the material transformations of human life. To put it differently, those approaches do not actually pose an inner *material determination* or necessity for the development of the revolutionary *political consciousness* of the working class. As pointed out before, they just provide an objective *context*, which is seen as spurring, accelerating or facilitating the *self-determining* movement of the subjective factor which 'reacts' to those external circumstances. But there is no real mediation between the materiality of social life and the political consciousness of workers. It is this mediation that the approach developed in this book attempts to provide.

As we have seen above, it is the historical necessity for the all-sided development of the universality of productive attributes of the workers beyond its capitalist 'integument' – generated by the alienated movement of capital itself – that is realised in the concrete form of the communist revolution. In this sense, the material determinations for the abolition of capital are not *external* to the concrete individuality of workers. Rather, they essentially pertain to their *subjectivity* as working individuals, that is, to their subjective powers to consciously organise the transformation of the environment into a means for the reproduction of human life. It is only when those material determinations of the development of human productive subjectivity emerge in the course of history that the proletariat acquires the social powers necessary to abolish their alienated general social relation. Hence, what this line of thought suggests is that *the revolutionary political consciousness of the working class can only be a concrete mode of existence of their productive consciousness*.

This has important broader ramifications for the nature of the revolutionary movement itself. Because overlooking that material determination of the political consciousness of the working class necessarily leads to conceiving of the revolutionary process in purely formal terms, that is, as a *mere* transformation of social forms. But what this approach suggests is that what the revolutionary movement realises (its content) is, fundamentally, the transformation of the materiality of the productive forces of the human individual and, *therefore*, of their social forms of organisation and development. In other words, it is about a *material* mutation of the production process of human life, which takes concrete shape through a *social* transformation, which, in turn, expresses itself through a *political* action.

This means, in the first place, that the revolution does not consist in the simple appropriation of the objectified form of the productive forces engendered by capital, although subjecting them to another form of social organisation. This is, broadly speaking, the standard classical Marxist understanding of the nature of the communist revolution (starting with Lenin's socialist use of so-called 'Taylorism', but also including the Council Communist reduction of the communist programme to the demand to 'get rid of the bosses', i.e. self-management of existing material forms of the production process).[2] Moreover, this also means going beyond the well-known 'Western Marxist' correction that consists of adding that the transformation of the social forms of human activity needs to be complemented by the development of an alternative 'socialist technology', which would replace existing forms of the material conditions of social labour that have been 'moulded' by the needs of capital.[3] In this alternative version, the external relation between material forms of the life process and social relations still persists. On the one hand, we have social relations. On the other, we have the materiality of the productive forces of the human individual. Since capitalist social relations have 'moulded' technology, the construction of a socialist society requires that both are transformed, as if it were possible to do one thing without doing the other. So conceived, the transformation of the material forms of the production process is once again reduced to an external objective condition, instead of being grasped as the immanent content of the communist revolution itself.[4]

---

[2] The formalism entailed by the Council Communist ideology of self-management has been insightfully highlighted many years ago by some currents of the so-called 'Neo-Bordigist Ultra-Left' in France (Négation 1973; Barrot and Martin 1974).

[3] See, for instance, Murray 2004; Arthur 2003c. See also Dyer-Witheford 2000, Chapter 3, for a review of Marxist approaches to 'technology-as-domination'.

In a nutshell, revolutionary practice is not about an external leap from capitalism to communism involving, on the one hand, the abolition of capital and, on the other, the construction of a communist society, as if they were different things. Hence, it is not that the historical powers of the capital form to develop the forces of production are exhausted and come to a halt, and then comes a social revolution which changes the social forms of the life process of humanity, in order to then set into motion the productive forces again, but now on a new basis. Rather, as a political action, working class revolution *is* the conscious organisation of that material transformation of the productive forces of the human individual through the change in the social forms of their organisation. This is why it makes no sense to consider that the 'objective or material conditions' for the revolution are ripe, but the 'subjective factor' is not. For those material *determinations* can have no concrete mode of existence and movement other than the consciously organised political action of the whole working class. To say that those material determinations can exist by themselves without the emergence of the fully conscious revolutionary subjectivity of the proletariat is as meaningless as the claim that value can unmediatedly exist in quantities of its substance and not in the form of money prices.[5]

Only because of all this does the revolutionary process transform both 'circumstances and human activity', i.e. involves 'self-change', as the third Thesis on Feuerbach claims.[6] This, I think, is also the underlying meaning of Marx and Engels's well-known passage from the *The German Ideology*:

---

[4] In other approaches, it is conceived of as an ethical question, part of a 'moral theory of human perfectibility' (Murray 2003). See also Gould (1978), who finds in Marx's *Grundrisse* a critique of the injustices of capitalism and sees the development of the fully developed social individual, hence the historical emergence of human freedom, as the realisation of justice.

[5] More generally, the question at stake in this discussion about the connection between productive forces and revolutionary consciousness is the difference between *immanent determination* of a form by its content (ideally reproduced through dialectics), and the exteriority of a lifeless mechanical relation between two self-subsistent entities (when grasped through logical representation).

> Both for the production on a mass scale of this communist consciousness, and for the success of the cause itself, the alteration of men on a mass scale is necessary, an alteration which can only take place in a practical movement, a *revolution*; the revolution is necessary, therefore, not only because the *ruling* class cannot be overthrown in any other way, but also because the class *overthrowing* it can only in a revolution succeed in ridding itself of all the muck of ages and become fitted to found society anew.[7]

Hence the general determination of the communist revolution: to be the political form of the riddance of the 'muck of ages' engendered by the production of relative surplus value, that is, the form taken by the historical production of the subjectivity of the 'rich individuality which is as all-sided in its production as in its consumption, and whose labour also therefore appears no longer as labour, but as the full development of activity itself'.[8]

---

[6] Marx 1976d, p. 4. The determination of revolutionary practice as a process involving self-transformation has been emphasised by various authors (Geras 1989; Barker 1995; Smith n.d.), who thereby provide a necessary warning against the uncritical glorification of existing forms of working class subjectivity as immediately 'fit to found society anew'. However, I think that, in most cases, this process of 'getting rid of the muck of ages' through 'self-transforming' political practice is seen in terms of the constitution of an abstract 'socialist culture of solidarity', with no reference to the materiality of the production process of human life. In other words, the question is idealistically seen as 'ethical' or 'cultural', but not fundamentally in terms of *productive subjectivity*. Lebowitz (2003) does grasp the need to focus on the latter. However, he sees the question as a matter of two different, externally related grounds for the development of the workers' revolutionary consciousness: on the one hand, the transformation of the materiality of the production process of human life and, on the other, the class struggle. By contrast, I am arguing that it is a question of the development of the materiality of human productive subjectivity taking concrete form through the revolutionary political action of workers. Mészáros provides perhaps one of the most suggestive approaches in this respect, explicitly addressing the need for determinate *material mediations* as the ground for the development of 'communist consciousness on a mass scale' and seeing the revolutionary process as the political *form* in which that material *content* is realised (1995, pp. 917–36). However, unilaterally sticking to the immediate concrete form of fragmentation and division through which capital's tendency for the production of universal productive subjects is realised, he cannot see the social necessity for the material transformation at stake as the *immanent* product of the alienated movement of the production of relative surplus value itself. The necessity of revolutionary subjectivity ultimately remains external to the general social relation presiding over the movement of modern society and is represented as consisting in the completion of a historic task that capital leaves unfinished. Again, revolution is seen as an external leap.

[7] Marx and Engels 1976a, pp. 52–3.

Revolutionary Subjectivity as Scientific Subjectivity

If the simplest *content* of revolutionary consciousness entails the self-awareness about the workers' alienated subjectivity, the question immediately arises as to what is the specific *form* of consciousness capable of discovering the former. The answer to this question is self-evident in the very intellectual process I have been unfolding in this book. In effect, inasmuch as the *critique of political economy* entails the reproduction in thought of the concrete unity of all the determinations of social existence implied in the necessity for the abolition of capital, it becomes determined as *the self-consciousness of the working class of the social determinations of its revolutionary action as an alienated subject* – an alienated subject, however, that has developed the material powers and historic task to put its own alienation (and hence its existence as working class) to an end. On the other hand, drawing on the methodological insights found in the work of Iñigo Carrera,[9] I have attempted to demonstrate throughout this book that the critique of political economy embodies such a transformative power only by virtue of its specific, *dialectical form*. In the first part of the book, this was just stated although not fully demonstrated. If successful, my methodologically minded reading of Marx's 'mature' dialectical critique of political economy, understood as the unfolding of the determinations of capital leading to the social constitution of the revolutionary working class, should have substantiated that point.

But there was another fundamental claim, only tangentially touched upon in the book, whose justification remained incomplete. I am referring to the historical determinations behind the distinction I made between representational scientific thought (or logical representation) and dialectical knowledge. As argued before, whilst the former is the mode of scientific knowledge determined as a form of capital's reproduction, the latter is the mode of scientific knowledge determined as the conscious organisation of the practical critique of the capitalist mode of production. However, a proper grounding of this distinction was not possible at that stage of the book. It is only now that I have discussed the determinations of the production of relative surplus value through the system of machinery that I can properly address that question.

---

[8] Marx 1993, p. 325.

[9] Iñigo Carrera 1992 and 2008.

In effect, we have seen that it is that particular material form taken by capital's valorisation that calls into life the powers derived from the scientific regulation of natural and social processes. In this way, capital increasingly determines scientific knowledge as the general form of productive consciousness organising the life process of society. Furthermore, we have seen that this also means that the productive consciousness regulating the labour process ceases to be subordinated to the immediate subjective experience of the wage labourer. In other words, it becomes an objective consciousness. However, this is an objective consciousness which is not the expression of the 'development of human powers as an end in itself'.[10] It is determined as a concrete form of the expanded reproduction of capital through the production of relative surplus value. In other words, it is an objective consciousness bound to reproduce its essential determination as an alienated consciousness. As I have already shown, firstly in my discussion of commodity fetishism and later when dealing with the relationship between class struggle and the valorisation of capital, it is by falling prey to the inverted appearance as free consciousness taken by alienated consciousness that human beings reproduce their own alienation. In this sense, the objective character of scientific knowledge confronts a limit which it cannot trespass without ceasing to be a concrete form of capital's perpetuation: it must be strictly developed in such a form that it does not discover its own immanent determination as an alienated consciousness. Thus, whilst needing to be scientific – hence objective – in order to produce relative surplus value, productive consciousness as an attribute of capital must remain incapable of fully seeing through the appearances presented by the real movement of social life and, therefore, cannot become *fully* objective. It has to remain *ideological*. How are these two requirements of the reproduction of capital reconciled?

I think that the discussion of the difference between dialectical cognition and logical representation in the first part of the book provides the key to answer this question. For the very *form* of representational science (i.e. its *method*) condemns it to grasp the relations between real forms in their apparent externality, and, therefore, to stick to some inverted appearance presented by them. Moreover, in being incapable of reproducing the contradictory movement of the real by means of thought, this form of scientific knowledge leads to uncertainty about its own objectivity. It therefore has to seek the foundation for its own objectivity outside of itself, in the alleged general rules of correct thinking – logic – guiding the thinking activity of an abstract subject of knowledge. In other words, it is an objective knowledge ultimately resting on *subjective* foundations and which is therefore unable ideally to reproduce the immanent self-movement of social and natural forms. Thus, we can now see the way in which the contradictory development of scientific knowledge within the boundaries of the reproduction of capital 'finds room to move', namely, by taking the form of *representational science*. As Iñigo Carrera emphatically argues, the historically specific determination of social existence (and hence of social consciousness) becomes therefore expressed in the very *form* of the process of scientific cognition of reality, i.e. in its *method*.[11] Since the mode of scientific cognition is a social form, as any other it must have a historical determination as well. Armed with that scientific consciousness, the political action of the working class becomes condemned to personify the need of capital to reproduce itself, instead of personifying the necessity to supersede itself into the free association of individuals.

---

[10] Marx 1991, p. 959.

Exactly the opposite line of reasoning applies to the form of consciousness that organises the action which, whilst alienated, in the course of its development transcends that very alienation. I am referring to the 'communist consciousness', the 'consciousness of the necessity of a fundamental revolution',[12] whose content, as we have seen, is the development of the 'control and conscious mastery of these powers' springing from 'the world-historical co-operation of individuals'.[13] This fully conscious organisation of the development of the social powers of the human being – 'the reality which communism creates'[14] – presupposes that the latter ceases to see the determinations of her/his social existence as an external force existing independently of the individuality of her/his conscious practical activity upon nature. And this can only be the product of a form of consciousness that is fully *objective* in character and that can therefore recognise and organise the immanent social determinations of human individuality beyond any appearance. This is recognised by Marx in the *Grundrisse*:

> The great historic quality of capital is to create this *surplus labour*, superfluous labour from the standpoint of mere use value, mere subsistence; and its historic destiny [*Bestimmung*] is fulfilled as soon as, on one side,

---

[11] Iñigo Carrera 2008, pp. 252–3.

[12] Marx and Engels 1976a, p. 52.

[13] Marx and Engels 1976a, p. 51.

[14] Marx and Engels 1976a, p. 81.

> there has been such a development of needs that surplus labour above and beyond necessity has itself become a general need arising out of individual needs themselves – and, on the other side, when the severe discipline of capital, acting on succeeding generations [*Geschlechter*], has developed general industriousness as the general property of the new species [*Geschlecht*] – and, finally, when the development of the productive powers of labour, which capital incessantly whips onward with its unlimited mania for wealth, and of the sole conditions in which this mania can be realized, have flourished to the stage where the possession and preservation of general wealth require a lesser labour time of society as a whole, and where *the labouring society relates scientifically to the process of its progressive reproduction*, its reproduction in a constantly greater abundance; hence where labour in which a human being does what a thing could do has ceased.[15]

Thus, in the communist association, not only will human activity take a mediated form, but as the social form of organisation of the universal development of 'human powers as an end in itself' through conscious co-operation, it will also elevate the social mediation of individual activity to new levels and forms. That is, the human process of metabolism will not return to the simplicity of pre-capitalist forms of social production, but, quite to the contrary, it will achieve even more complex forms than the ones produced under the alienated rule of capital. For the fully developed social individual, the problem at stake will be the integration of her/his individual productive action into the activity of a collective body composed out of the universal and all-round co-operation of human beings. And thought being the way in which the social forms of the life process express themselves in the human head, how can the regulation by means of thought of such a complex process of reproduction take the form of a consciousness not involving mediation? Certainly, then, social relations will become 'transparent' under the free association of producers. However, this will be the result not of an *immediate* insight,[16] but of a scientific consciousness that passes through all the mediations involved in the fully conscious organisation of what will be a highly complex form of human activity. The necessity for a scientific comprehension of the social determinations of human life will not disappear under communism, but will become the general form in which individuals organise their life activities. Paraphrasing Marx, there is no royal road to the self-conscious organisation of directly social human practice! As he put it already as early as the *Paris Manuscripts*,

---

[15] Marx 1993, p. 325, my emphasis. It is remarkable that in this passage Marx states that human beings only do that which is specifically human and cannot be done by 'things'. Although he does not say it explicitly, it seems obvious to me that much if not all of what is now done manually is among those tasks that can be done by 'things'. In other words, manual direct labour is one of those things that should be consigned to the dustbin of history by the communist revolution. 'Really free working' will fundamentally (if not exclusively) involve *intellectual* labour. This should come as no surprise, since it is the regulation of the life process by means of *thought* that, according to Marx, from the *Paris Manuscripts* right up to *Capital*, constitutes the specifically human form of the material life process.

> My *universal* consciousness is the *theoretical* form of that whose *living* form is the *real* community, society, whereas at present *universal* consciousness is an abstraction from real life and as such in hostile opposition to it. Hence the *activity* of my universal consciousness – as activity – is my *theoretical* existence as a social being.[17]

Yet social being takes in the capitalist mode of production an alienated form. Thus, in its first historical manifestation, this 'universal consciousness' emerges as an alienated attribute of capital, albeit of its immanent necessity to transform the materiality of the human reproduction process beyond the capital form. Whilst *necessarily scientific*, 'communist consciousness' must therefore acquire a form that allows it to penetrate all inverted appearances presented by social being in order to discover its own alienated nature. At this stage of my argument, it is self-evident what this form is: dialectical knowledge. Only this form of knowledge, as 'the reproduction of the concrete by means of thought', ideally expresses the material power to organise the communist abolition of capital. *Hence, whilst logical representation is the scientific method determined as a form of capital's reproduction, dialectical knowledge is the mode of scientific cognition determined as the form of capital's transcendence and, a fortiori, of the free association of individuals* (*'the reality that communism creates'*). In brief, it is a question not just of abolishing the separation between intellectual and manual labour through the reduction of the latter to 'quantitative and qualitative insignificance', but, fundamentally, of the revolution in the very general form of scientific intellectual labour itself.[18]

---

[16] Cf. Cohen 1972.

[17] Marx 1992b, p. 350.

[18] Inasmuch as it is determined to emerge for the first time in the course of history in the alienated form of the conscious organisation of the abolition of capital, dialectical knowledge initially takes the concrete form of *critique of political economy*. Once liberated from

Revolutionary Subjectivity as Consciously Self-Organised Subjectivity

The rejection of the need for (dialectical) scientific knowledge to organise the transformation of the capitalist mode of production into the free association of individuals has generally come from the abstract critique of Leninist 'vanguardism and substitutionism' by so-called libertarian currents of Marxism.[19] Holloway's recent work is a case in point. For him, the postulation of the need for a scientific organisation of communist revolutionary activity can only lead to the separation between the 'intellectual elite' and the masses. In turn, this would mean that the revolution ceases to be the self-emancipation of the working class and becomes the changing of society by the self-proclaimed vanguard on behalf of the working class.[20]

Clearly, Holloway is not arguing for a complete refusal of the need for critical theory. He explicitly acknowledges that 'intellectual work is part of that struggle'.[21] However, afraid that this claim could lead him to intellectual elitism, he then hastens to add that although it is another expression of the class struggle, revolutionary thought does not enjoy any 'privileged role' in the practical critique of capital. The fully developed consciousness of the social determinations of alienated human activity is just another form of the critique of alienated labour, coexisting alongside social struggles based on more or less immediate consciousness. Or, in Holloway's own words, theory is simply 'a peculiar way of articulating our [the theorists'] participation in the conflict in which all participate'.[22] The real, material unity of theory and practice to be achieved by the critical-revolutionary activity of the proletariat thus dissolves into the purely formal unity consisting in the coexistence of 'critique in theory' and 'critique in practice'.

---

its existence as an alienated attribute of capital existing in the heads of the self-abolishing proletarians, dialectical science does not wither away, but must acquire a new concrete form: *human* natural science or the *natural science of humanity* (Marx 1992b, p. 356).

[19] This rejection is a particular expression of a more generalised 'cultural mood' in the present times of general political retreat of the working class. In the realm of theory, this mood is expressed in the emergence of postmodernism as the dominant ideological form taken by social theory. In the realm of practical politics, this acquires expression in the anti-intellectualism characterising the current 'anti-globalisation' movement. For concise suggestive reflections on this, see Aufheben 1992, pp. 1–2.

[20] Holloway 2002a, p. 30.

[21] Holloway 2002a, p. 63.

[22] Holloway 2002a, p. 30.

By contrast, I think that when its concrete determinations are properly grasped, far from leading to a Leninist separation between 'party direction/intellectuals' and 'masses', the scientific organisation of political action actually constitutes its only genuine practical critique. In effect, the general material content of the conscious revolutionary action of the proletariat suffices to understand why it can definitely *not* take the form of the institutionalisation of the separation of the conscious organisation of that action from its execution proper. And this is not just a matter of an abstract moral superiority of radically democratic forms of social organisation over hierarchical ones. Rather, it is but a consequence of the materiality of the social transformation at stake, namely, the production of the consciousness about the social character of human transformative action as the general social relation reproducing human life. In other words, this is the consequence of the necessary *conscious* nature of such a collective process of social transformation, which can only be such precisely for being the organic unity of the conscious transformative practice of each individual. Only in this way can such action be fully conscious and thereby acquire the plenitude of its transformative powers.[23]

---

[23] The reduction of the communist transformation to a question of radical democracy has been a longstanding characteristic of the anti-Stalinist left and has gained new life in recent times within the so-called anti-globalisation movement. This 'obsession' with democracy is an evidently understandable but *abstract* reaction of the revolutionary left to the bureaucratic experience of the Soviet Union (and also of Social Democracy in Western Europe). The critique of this 'formalist consciousness' with its 'fetishism of organisational forms' has also been one of the themes insightfully discussed by the 'Neo-Bordigist' ultra-left in France (Barrot and Martin 1974). As Goldner notes, the critique of capital from the perspective of radical democracy basically follows from the representation of capital as essentially a *hierarchical relation of power* (Goldner 1981). But as value-in-process, capital is a materialised form of social mediation that becomes the self-moving subject of human life, a determination that derives from the essentially unconscious form of social reproduction through the commodity form. Hence, the content of the communist transformation is not the democratisation of society, but the abolition of the determination of the human life process as the material bearer of the self-expansion of capital through the conscious association of fully developed social individuals. Inasmuch as its production involves the conscious organisation of collective human practice as an attribute borne by each human individual, one could anachronistically call that 'democratic'. But without a critique of the commodity form, money form, capital form and the abstractly free subjectivity of the private individual, the call for radical democracy mystifies rather than throws light on the communist revolution.

Thus, the monopoly over the conscious organisation of the general social character of human action by some individuals (let us say, the 'intelligentsia') can signal just one thing, namely, that the rest of the members of society are acting *un*consciously, uncritically accepting the appearance that the would-be leaders really are acting consciously, no matter how democratic the mediations between those two poles, or how much the leaders are predisposed to 'learn' from the spontaneous movement of the masses.[24] When Marx spoke of communism as the conscious association of individuals, he really meant it. And this is not just a matter of 'feeling like' associating with others, or of instinctively doing it under the pressure of external circumstances (even less a question of ethical duty), but more so of being fully and objectively aware of the social necessity of this association in the totality of its determinations.[25] On the other hand, this is why the reproduction in thought of the social determinations of the political action that accomplishes said transformation of the whole process of human metabolism (dialectics), must be, by its very essence, a collective class product, whose production involves *all* individuals concerned. The development of science as the practical critique of capital thereby involves not only the *transformation* of the mode of scientific cognition, but also its *generalisation*. To put it simply, dialectical knowledge (hence, 'communist consciousness') must become an attribute borne by each member of the self-abolishing proletariat as a whole, regardless of the particular form of productive subjectivity inherited from the different role played as partial organs of the production and circulation of capital with which they enter the revolutionary process. Only in this way can the 'genuine bond of consciousness and action' (Lukács) be established in the course of human history, thereby making the immediate *material* unity of theory and practice become the general social relation reproducing human life.

---

[24] See Shandro 1995 for an interesting but futile attempt to save Lenin's theory of the party.

[25] Thus it is in the very essence of dialectical knowledge to require the reproduction in thought of the social determinations of human purposeful activity in the singularity of each individual action. This is why, by its very form, dialectical cognition is inherently self-critical: on each occasion it is set into motion, it subjects its existing forms to criticism (Iñigo Carrera 1992). I shall return to this below.

Revolutionary Subjectivity 'Proper' and the Revolutionary Conquest of the Political Power of the State

We have seen in the previous chapter that Marx's dialectical exposition in *Capital* culminates with the 'expropriation of a few usurpers by the mass of the people',[26] a process which he identifies as immediately coinciding with the 'point at which they [the centralisation of the means of production and the socialisation of labour] become incompatible with the capitalist integument', which therefore 'is burst asunder'.[27] I have already mentioned that this concise statement about the revolutionary transcendence of capital is rather problematic. The reason for this is that it conflates two qualitatively different determinations of the 'Historical Tendency of Capitalist Accumulation': the expropriation (hence abolition) of the bourgeoisie or capitalist class and the abolition of capital itself as a materialised social relation.

Yet this conflation between those two distinct (yet related) social processes lies at the basis of the traditional or orthodox Marxist conception of revolutionary subjectivity and the abolition of the capitalist mode of production. This conception actually follows from the ideological representation of the social relations of production as juridical property relations. In effect, socialism was seen as complete state ownership of the means of production by a workers' state. The proletarian conquest of state power alongside the expropriation of the bourgeoisie was accordingly represented as synonymous with the transcendence of the capitalist mode of production.[28] As should be evident from my critical reading of *Capital* and the *Grundrisse*, this conception of the overcoming of capitalism substantially differs from Marx's views.

---

[26] Marx 1976g, p. 930.

[27] Marx 1976g, p. 929.

[28] See Chattopadhyay 1992, 1996 and 2010, for textual evidence of this conception of socialism in Soviet Marxism. In other words, socialism was seen as a *transitional society* between capitalism and communism. This distinction was usually legitimised with reference to Marx's discussion of a lower and higher phase of the society that supersedes the capitalist mode of production in the *Critique of the Gotha Programme* (Marx 1989a). However, as Chattopadhyay demonstrates in the works just cited, the orthodox Marxist differentiation between a socialist and communist society represents a misreading of Marx's argument in the *Critique of the Gotha Programme*, which referred to two phases *within* the communist association of individuals, interchangeably referred to as Communism and Socialism. Incidentally, this misreading is not exclusively a Soviet or orthodox Marxist feature. For instance, despite Camatte's otherwise radically unorthodox reading of Marx, in *Capital and Community*, he mistakenly posits the dictatorship of the proletariat as one of the *three* successive *post-capitalist* phases (the other two being 'lower socialism' and 'communism', as in the Leninist reading of Marx's discussion in the *Critique of the Gotha Programme*). See Camatte 1988, pp. 121–3, 139.

Thus, whatever the ambiguities of Marx's formulation in the passage from the chapter on the 'Historical Tendency of Capital Accumulation' referred to above, a cursory reading of his so-called 'political writings' makes evident that he was very clear about the '*unity-in-difference*' between the expropriation of the bourgeoisie and the abolition of capital. To begin with, this is condensed in the political programme of the working class to be implemented through the revolutionary 'conquest of political supremacy' contained in the *Communist Manifesto*, whose *immediate* economic content unequivocally comes down to the absolute centralisation of capital in the form of state-property – hence the abolition of the bourgeoisie – and does not involve the abolition of the capitalist mode of production.[29] As Chattopadhyay competently shows,[30] for Marx the revolutionary conquest of political power together with the expropriation of the bourgeoisie were the *necessary forms* in which to *start* the process of transformation of the capitalist mode of production into the free association of individuals. But unlike the conception found in Lenin and orthodox Marxism in general, Marx was very clear that the political rule of the working class 'does not by itself signify the collective *appropriation by society*, and does not indicate the end of *capital*'.[31] The 'dictatorship of the proletariat' was, for Marx, a *period within the capitalist mode of production* – hence, not a non-capitalist transitional *society* – in which the latter was to be entirely revolutionised in every nook and cranny up to the point of fully preparing wage workers for their self-emancipation – hence for their self-abolition as working class.[32] This has several implications beyond those discussed in Chattopadhyay's rigorous but mainly exegetical commentary.

First, during that period, workers continue to be wage labourers. The sale of labour power as a commodity to a single state-owned capital for a wage continues to be the general *indirect* social relation regulating the establishment of the unity between production and individual consumption (and hence mediating the reproduction of the worker's life). In this sense, material reproduction as a whole is not *fully* socialised under those circumstances. Although the allocation of the total labour power of society in its different concrete forms is no longer privately organised in formally independent direct production processes, the part of the total product of social labour that corresponds to the reproduction of labour power still takes the commodity/value form.[33] Consequently, the process of metabolism does not attain social unity in a completely direct form and the social character of labour therefore continues to take the form of capital, i.e. of an objectified social power that dominates the direct producers. In effect, as with simple co-operation, the constitution of an immediately collective productive body is not yet the direct product of the fully self-conscious association of the producers, but is set into motion with the previous mediation of the sale of their labour power as private and independent individuals to the single state-owned capital. Therefore, whilst this figure of the collective worker now personifies the direct organisation of all the functions of the immediate production process in its totality, 'their co-operation only begins with the labour process, but by then they have ceased to belong to themselves'.[34] Their labour belongs to the total social capital, which now immediately exists as a singular capital that subsumes the co-operation of the collective labourer as a whole. In other words, in the reified form of money-as-capital, the materialised general social relation of workers still *pre-exists* and *autonomously sets into motion* their productive co-operation with the only alienated purpose of expanding its own magnitude, i.e. of producing surplus value.

---

[29] Marx and Engels 1976b, pp. 504–5. Strictly speaking, Marx and Engels's programme is even more timid. They suggest the *gradual* expropriation of the bourgeoisie, which would eventually lead to the absolute centralisation of capital as state property.

[30] Chattopadhyay 1992, pp. 92–3.

[31] Chattopadhyay 1992, p. 93.

[32] Ibid.

In the second place, no matter how radically democratic is the self-government of the direct producers during the dictatorship of the proletariat (and Marx thought it would be),[35] they still confront the social determinations of their individual life activity as an alienated power.[36] Similarly to workers' co-operatives within an individual private fragment of social labour, general political self-government by wage labourers is tantamount to the self-management 'of the use of the means of production to *valorize their own labour*'[37] for the total social capital. That wage workers have dispensed with the mediation of the direct relation established with a capitalist or a state bureaucrat in the labour process does not change the fact that they are self-organising the *alienated objectification of their productive activity*. Certainly, they no longer submit their productive subjectivity to the consciousness and will of another person (or rather, personification). But they still have to submit their conscious action to the unity of society existing in the form of a self-activating objective process that they do not control in a fully conscious manner. The despotism and coercion of the production process of human life determined as material bearer of capital's valorisation process does not disappear. It only takes the concrete form of a democratically self-imposed compulsion – yet one that is objectively determined behind their backs – to expand the materialised social relation.[38] In other words, even if, for the sake of argument, we assume with Marx that the *Commune* was 'the political form at last discovered under which to work out the economical emancipation of Labour',[39] this communal *political* organisation still represents, *pace* Lebowitz,[40] a form of existence of the *capitalist state* and not a 'workers' state'.[41] The form determination of the state is to be the political mode of existence of the movement of the total social capital, i.e. the objectified embodiment of the direct organisation of the unity of the conditions of social reproduction in its alienated capital form. Neither the fact that this general political representation comes to be personified by the rule of wage workers as a class, nor the radically democratic character of its institutional or organisational structure transform this content of the state, the basis of which lies in the economic mediation of the unity of social labour through the commodity, money and capital forms. Yet I shall argue below that *precisely by virtue of this content of the state* the working class can achieve its self-abolition (and hence the abolition of both capital and the state) only through the 'conquest of political supremacy'.

---

[33] Iñigo Carrera 2008, p. 38.

[34] Marx 1976g, p. 451.

[35] See Draper 1974, for a textual analysis of this point.

[36] Iñigo Carrera 2008, p. 26.

[37] Marx 1991, p. 571, my emphasis.

Thirdly, this means that, although taking place in the form of a revolution, the political action of the working class that conquers state power and expropriates the bourgeoisie cannot be the product of a fully self-conscious subjectivity. Otherwise it would not continue to see the social determinations of human individuality as external to the latter and hence as objectively borne by the product of labour. It is not only an alienated action, but also one that is still unaware of its own alienated nature as the personification of the movement of the total social capital. In other words, the immanent content, which determines this action, still operates behind the backs of workers, who still see their political activity as an affirmation of their abstractly free subjectivity. By 'getting rid of the bosses', they now attain full *personal* 'self-determination' *as collective commodity producers and owners*, overcoming both the relative mutilation that their personally free productive consciousness experienced by virtue of the mediation of the figure of the capitalist in the direct process of production (and, one could add at this stage, in circulation); and, again assuming with Marx the 'Commune form' taken by the dictatorship of the proletariat, also that of 'state parasites, richly paid sycophants and sinecurists' in the general political representation of the unity of the total social capital. Nevertheless, the content and result of this political action is not the self-abolition of the working class, but rather its reproduction, hence that of the valorisation of capital.[42] The dictatorship of the proletariat represents the plenitude of the affirmation of the specific productive powers of the doubly free worker and, for this reason, it also constitutes the plenitude of her/his alienation: under these circumstances, the separation and alienation of the labourer from the means of production does not even need the mediation of the private property of the non-labourer.[43]

---

[38] To make the point as clear as possible, it might be the coercion emanating from a democratically reached consensus in a universal assembly which, as long as its individual members continue to see themselves as private and independent, will still confront their species-powers as an external force, a 'general will' to which she/he must submit her/his activity. Thus, she/he will experience the mandates generated in the assembly (including attendance to the assembly itself) as an obligation, moral or legally sanctioned (even if she/he participated in the 'decision making' process). Only when the human being *objectively and fully consciously* recognises the social determinations of her/his individuality, in communism, will the unity of society cease to appear as an alien force that dominates the individual.

[39] Marx 1986, p. 334.

[40] Lebowitz 2003, pp. 189–96; 2009, Chapter 18.

[41] I say 'for the sake of argument' because, in my view, in those sorts of grandiose statements Marx 'the militant' got carried away and came dangerously close to offering 'recipes for the cook-shops of the future'. A similar point could be made about many of Marx's arguments in the *Critique of the Gotha Programme*.

In this sense, the form of political subjectivity that undertakes the revolutionary expropriation of the bourgeoisie by conquering state power is *not* the one that expresses the historical necessity for the self-conscious transcendence of capitalist production and whose determinations have been the main focal points of this book's investigation. In other words, it is not *revolutionary subjectivity 'proper'*. It is only the expression of the clash of the production of relative surplus value with the mediation of private property, i.e. of the need for capital, as a moment of its own expanded reproduction, to take the form of a directly collective property, the immediate 'form of social capital (capital of directly associated individuals) in contrast to private capital'.[44] Even more so than the joint-stock companies mentioned by Marx in Volume III of *Capital*,

---

[42] Iñigo Carrera 2008, p. 37.

[43] Ibid.

[44] Marx 1991, p. 567.

'this is the abolition of capital as private property within the confines of the capitalist mode of production itself'.[45]

In the first place, this politically enforced unification of the 'entire social capital as one single capitalist company' under state ownership is the necessary form in which the production of relative surplus value drives the alienated socialisation of personally free labour to its limits *within the capitalist mode of production*, i.e. it is the necessary mode of motion of the *absolute centralisation of capital*. But secondly, it is the form in which the total social capital gets rid of the figure of the capitalist when the very material conditions of production (and circulation) make her/him superfluous for the valorisation process. In effect, the complexity and scale of the co-operation of the collective worker of large-scale industry render the subjective powers of the capitalist incapable of personifying in the name of her/his capital even the unproductive labour of superintendence of the productive organs of the former.[46] Thus, as the separation of active function in the reproduction process from capital ownership reaches completion, its existence becomes a barrier to the accumulation of capital itself. The parasitic nature of the capitalist, though not yet of capital, thereby becomes materially concrete.[47] And note that this expresses an alienated necessity of the accumulation of the total social capital: the consumption of the capitalist represents a deduction of the potential surplus value that could be devoted to its self-expansion.

Yet given that the centralisation of capital is the most potent form for the production of relative surplus value and, *a fortiori*, for the alienated historical movement toward the constitution of directly socialised universal productive subjects, the conquest of political supremacy and the expropriation of the bourgeoisie become 'a necessary point of transition towards the transformation of capital back into the property of the producers' and 'towards the transformation of all functions formerly bound up with capital ownership in the reproduction process into simple functions of the associated producers, into social functions'.[48] In this sense, the 'ultra-leftist' political programme for 'immediate communisation' is, broadly speaking, right *as far as the content of the political action of the fully developed, self-conscious revolutionary subject is concerned*.[49] It is wrong to think that such a form of subjectivity can emerge in the course of history without passing 'through long struggles, through a series of historic processes transforming circumstances and men',[50] and which can only come about as the result of the 'conquest of political supremacy' that undertakes the absolute centralisation of capital.[51]

---

[45] Ibid.

[46] As Marx himself notes (1976g, p. 549; 1991, pp. 510–11), with large-scale industry all the functions of supervision, coercion and management come to be personified by a partial organ of the collective labourer.

[47] Incidentally, the confusion over the parasitic nature of the capitalist and that of the capital form as such underlies Negri's views of the present, 'Postfordist' forms of human co-operation as carrying in their immediacy – that is, without the mediation of additional material transformations – the potentiality to explode the capital relation. See Negri 1992, pp. 65–8; Negri and Guattari 1999, pp. 156–60.

[49] See Théorie Communiste 2003; Aufheben 2003 and 2004; Endnotes 2008b and 2008a. A useful critical assessment and discussion of this political milieu can be found in the recent collection of essays edited by Noys (2011).

[50] Marx 1986, p. 335.

[51] The problem with the traditional view on the historical production of communism is not, as the aforementioned ultra-leftist milieu would have it, that it postulated the need for the mediation of the dictatorship of the proletariat (cf. Endnotes 2008b, p. 13). As argued above, the problem is that it conceived of the dictatorship of the proletariat as a *post-capitalist transitional society*, whereas my claim is that it is a necessary form taken by the development of the capitalist mode of production, and which is presupposed by the constitution of revolutionary subjectivity 'proper'. At least formally, one could argue that *Théorie Communiste*'s version of the 'communisation' thesis does acknowledge the need for historical mediations in the becoming of revolutionary subjectivity. Thus, they attribute a historical role to what they call the 'programmatism' of the 'old workers' movement' in the development of the capital relation up to the point at which it can be immediately abolished (Théorie Communiste 2008, pp. 155–66). Unlike the views of those associated with the *Troploin* journal (Dauvé 2008; Dauvé and Nesic 2008), they consider that the determination of the supersession of capital as the immediate content of the proletarian struggle is a *result* of the historical development of the capitalist class relation and not its 'invariant' character (a 'produced overcoming'; see Endnotes 2008a, pp. 215–16). However, in their idiosyncratic account of the history of the capital relation, so-called 'programmatism' is said to have exhausted its historical *raison d'être* in the development of the revolutionary working class *without* having actualised its full potentiality through the absolute centralisation of the total social capital on a world scale. From the perspective adopted in this book, such a situation is quite simply an oxymoron; the kind of subjectivity that immediately personifies the fully self-conscious abolition of the capital form through the revolutionary production of the communist association of individuals (i.e. revolutionary subjectivity 'proper') cannot skip over the necessary mediation of the *actual historical realisation* of the absolute centralisation of capital in the political form of the global dictatorship of the proletariat. At bottom, the more general underlying weakness of the approach of collectives such as *Théorie Communiste* and *Endnotes* (of which their unconvincing historical narrative is a concrete expression) is that despite their own claims to the contrary (Endnotes 2008a, p. 215), they fail to supersede the dualism between

This need to 'take power' is not simply grounded in strategic considerations, insofar as historical experience shows that refusal to take state power has only resulted in those aiming at revolutionary change being eventually thrashed by it.[52] Nor is it the way in which the workers can freely 'realize their own need for self-development'[53] by gradually depriving capital 'of its greatest weapon – the dependence of wage-labourers upon it for employment and for the ability to satisfy their requirements'.[54] Instead, it is grounded in the alienated nature of the workers' subjectivity and, therefore, in the alienated forms necessarily taken by its development and transformation.

As I argued in Chapter 6, the inverted character of capital-determined social existence implies that the subjectivity of commodity owners 'changes skin' only as the necessary mediation of the autonomised self-movement of forms of objectivity. Thus, workers cannot freely self-transform their form of subjectivity in order to develop a revolutionary political consciousness. Insofar as the latter is but an expression of the workers' *productive* subjectivity, the only way of unfolding the necessary underlying transformation of the production process is to 'force capital' to develop that specific revolution in the material conditions of social labour through the production of relative surplus value. As we have seen, workers can obviously not do this by turning their back on their objectified general social relation and its economic and political forms (i.e. capital and the state).[55] There is no exteriority to their

---

objectivism and subjectivism. Thus, revolutionary action is not seen as an alienated action that personifies a necessity of the accumulation of the total social capital. Instead, it is ultimately conceived of as abstractly self-moving, yet 'conditioned' or 'shaped' by the historically changing objective configuration of the subsumption of labour to capital. In turn, the latter is idiosyncratically characterised in terms of 'the degree of integration of the circuits of reproduction of capital and labour-power' (Endnotes 2008a, p. 212) and not on the basis of the qualitative determinations of the productive subjectivity of the collective labourer.

[52] Bensaïd 2005, p. 179.

[53] Lebowitz 2003, p. 190.

[54] Lebowitz 2003, p. 192.

[55] See Holloway 2002b. Holloway's argument for the refusal to take political power is that the state is a form of existence of capital and that 'its own continued existence is tied to the reproduction of capitalist social relations as a whole'. This might be the case, but so is the very subjectivity of wage labourers. Would that mean that workers should refrain from acting politically in any form because they are a mode of existence of capital? Clearly, this is not Holloway's conclusion. The 'trick', as I have already argued, is that Holloway eventually glorifies a residual or pristine element of the worker's subjectivity, which remains external to capital.

determination as 'executors' of the alienated movement of their social being (the accumulation of the total social capital). On the contrary, they have to act upon it in order to make it reach its absolute limit as an alienated mode of development of productive subjectivity. And this can only come about through the absolute centralisation of the entire social capital as the property of a world state.[56] Only in this way can workers impel capital to unleash 'the historic processes transforming circumstances and men'[57] in the forms needed by their constitution as alienated yet fully conscious revolutionary subjects. As such bearers of revolutionary subjectivity 'proper', workers shall eventually become aware of their world-historic, truly emancipatory task: consigning capital-determined alienation to the dustbin of (pre)history through the production of the conscious association of the fully developed social individuals.[58]

Final Words: Whose Revolutionary Action is It Anyway?

The reader might be tempted to grasp what I have been doing in this book as an exercise in 'Marxology', yet another *interpretation* of the works of Karl Marx. However, the very form of the dialectical method as discussed in this work already provides us with a first reason as to why it should not be seen as an 'interpretation of texts'.[59] As argued above, the point of departure of any materialist dialectical investigation must be the conscious organisation of the form to be given to *our* transformative action in order to realise with the latter the potentialities existing in our reality (the here and now) to 'change the world'. That is why I have been referring to this book as a *critical reading* of Marx's work, a necessary moment of the broader question of the positive development of the critique of political economy, which in turn is but the conscious organisation of the practical abolition of capital.

---

[56] Iñigo Carrera 2008, pp. 37, 124.

[57] Marx 1986, p. 335.

[58] Note that the distinction between the absolute centralisation of capital through the conquest of political supremacy and the revolutionary abolition of the capital form is essentially analytic. It refers to two necessary *qualitative* 'moments' of the transcendence of the capitalist mode of production into the free association of individuals or communism. Whether they will crystallise as two neatly defined historical periods, or as phases of a single historical process, is something that cannot be said today without, again, relapsing into providing 'recipes for the cook-shops of the future'.

[59] Iñigo Carrera 2008, p. 317.

In this sense, what should interest the contemporary reader of Marx's works is not 'what he really said', but rather the development of the objective knowledge of the social determinations of *contemporary* social forms of existence of capital and, fundamentally, of *our* political action among its concrete forms. As argued earlier, this process cannot be spared from the development of the laborious analytical journey from the concrete to the abstract, and the subsequent synthetic return from the abstract to the concrete. In this endeavour, the reading of Marx's works, i.e. of socially pre-existing objectifications of dialectical knowledge, can only serve to *enhance* the potency of our process of cognition. In effect, inasmuch as it is an original development from the *individual* point of view but a process of *re*-cognition as far as its *social* character is concerned, we can engage in the inquiry with the advantage of being able to individually appropriate already existing social powers of the 'general intellect', thereby giving our own process of self-knowledge increased agility and efficiency ('real economy of time', as Marx puts it in the *Grundrisse*).[60]

On the other hand, this necessity to *re-cognise* all the mediations involved in the forms of present-day social being is what gives the very form of dialectical cognition an intrinsically *self-critical* quality. Thus, in my presentation of the different forms of capital as the alienated subject of modern social life through the reconstruction of Marx's texts, I was both following the immanent necessity of those forms *and*, in the very same movement, providing a critique of Marx's own discoveries. As we have seen, one of the critical results of this investigation has been the awareness of the incompleteness of the unfolding of the determinations of revolutionary subjectivity in *Capital*. A huge gap exists between Marx's exposition of the transformations of the *materiality* of the productive subjectivity of the collective labourer and the *politically* revolutionary subjectivity outlined in the end of Volume I of that work. Although I argued that the core elements for such a systematic dialectical presentation of the social necessity of revolutionary subjectivity could be found in the *Grundrisse*, it was necessary to put together those pieces – scattered in an unpublished manuscript – and integrate them as necessary mediations into the reproduction in thought of the qualitative determinations of the real subsumption of labour to capital.

Furthermore, in this concluding chapter I tried to go beyond Marx in the specification of the determinations of the revolutionary subject. I essentially did this by explicitly addressing aspects of revolutionary subjectivity that, I think, are only implicit in Marx's work (although they certainly *are* there):

---

[60] Iñigo Carrera 2008, pp. 317–18.

namely, its alienated nature; its being a concrete expression of the historical transformations of productive subjectivity; the specific form of its essentially scientific character (hence the historicity of scientific method); and finally, the *materiality* of its organisational form (the overcoming of the separation between 'conception' and 'execution' in the political action of the working class).

And yet, even if including more concrete mediations than Marx, this book evidently still remained at a considerably high level of abstraction. As much as Marx himself, I also considered 'bourgeois society in the long view and as a whole'.[61] That is, with the exception of some digressions in passing, I only addressed the *essential determination* and *general tendency* behind revolutionary subjectivity, with no attention to the concrete forms in which the latter unfolds in the course of the history of capitalist development and, more importantly, in the *contemporary* forms of the essentially global accumulation of capital. On the other hand, I believe that the approach presented here does provide us with the key to such an investigation, namely, the movement of the twofold contradiction between universality and particularity, and between the expansion and degradation of the productive subjectivity of the different organs of the collective labourer, as it springs from the production of relative surplus value.[62]

As a necessary moment of the class struggle, a most urgent task arises for that partial organ of the collective labourer that is nowadays responsible for the production of the critical scientific knowledge of capitalist social forms (i.e. communist intellectual labourers). What is required is dialectical research on contemporary concrete forms in which the alienated development of the productive subjectivity of the workers towards its fully developed universality realises itself through its own negation, that is, by fragmenting the different partial organs of the collective labourer and by keeping the productive attributes of the labourers (even when they are expanded as in the case of intellectual labourers) miserably bound to being those required by the material forms of the production of relative surplus value.

Needless to say, and at this stage of our investigation this might sound redundant, this does not entail an abstractly theoretical interest, but is the necessary method for discovering the form of political action that could mediate the immediate needs of workers with the ‘historical interests of the proletariat as a whole’, i.e. the development of the productive subjectivity of the global collective worker beyond its alienated capitalist form.

Labour

Guido Starosta

INTRODUCTION

The centrality of the notion of 'labour' in Marx's critical social theory and in particular its determining character as the key to his materialist perspective on human society and its historical development, seem to be beyond dispute.[1] It is also quite uncontroversial, at least on the basis of textual evidence, that Marx presented the simplest or most general determination of labour as consisting in the conscious and voluntary transformation of external nature by human beings in order to appropriate its potentialities for the satisfaction of human needs. Controversies arise, however, when it comes to establishing if Marx was right, whether in his views on the essential determinations of labour or concerning its defining role in the constitution and development of the forms of existence of human subjectivity.

Against the backdrop of these debates, this chapter will provide a comprehensive discussion of the notion of labour in Marxian social theory, with the aim of providing a systematic reconstruction of the 'unity of its many determinations', which appear scattered in Marx's own writings. In order to do so, it will address the multiple dimensions and aspects associated with this essential concept, both as they were originally formulated by Marx and in some of the main subsequent debates outside and within Marxism to which the former gave rise. Taking as the point of departure the simplest determination of human labour as conscious life-activity, this chapter will probe further into the different, more concrete determinations which comprise the material character of production and its changing historical modes of existence. Through this close scrutiny of the concept of labour, the chapter will make two fundamental points. In the first, and substantively, it will bring out the centrality of the material determinations of human productive subjectivity for the comprehension of the content and historical trajectory of society. Second, and formally, it will show that it is possible to find an underlying 'systematic' unity which articulates those different determinations of the Marxian concept of labour into a 'concrete whole'.

MARX'S DISCOVERY OF LABOUR, OR CONSCIOUS LIFE-ACTIVITY, AS HUMANITY'S 'SPECIES-BEING'

Marx's discovery of the centrality of labour to social life can be traced back to the *Paris Manuscripts* of 1844 (Marx, 1992a [1844]) and was a direct result of Marx's first attempt at the critical investigation of the specific nature of modern society through the critique of Hegel's *Philosophy of Right* (1991 [1821]), i.e. through an analysis of bourgeois political forms. As Marx himself tells us in the short intellectual 'autobiography' found in the *Preface to the Contribution to the Critique of Political Economy* (1992b [1859], the main conclusion he reached was that the key to the comprehension of the specific nature of capitalist society was not to be found in the critique of the doctrine of the state. Instead, the critique of modern society had to start with the critique of political economy in order to, then, continue into a critique of the state (1992b [1859]: 425–6). The former was the science that was able to penetrate the 'internal physiology' of the modern world to be found in 'civil society' and, more precisely, in 'private property'.

In light of this conclusion, in the *1844 Manuscripts* (1992a [1844]) Marx turns his attention to the material reproduction of human life as the key to the understanding of society and its historical development. As Arthur points out, in that early text Marx 'for the first time … attributes fundamental ontological significance to *productive activity*. Through material production humanity comes to be what it is … material production is the "*mediation*" in which the unity of man with nature is established' (1986: 5). In other words, Marx identifies labour or productive activity as the specific form in which humanity reproduces its existence as part of nature.

This means that although the human life-process undoubtedly possesses its qualitatively differentiated 'species-character', constituted by 'the nature of its life activity' (Marx, 1992a [1844]: 328), it nonetheless remains a concrete form of the natural *life-process in general*. In this sense, labour realizes in its own peculiar fashion the determinations entailed by *any* form of life-activity, namely: being a natural process of *self-reproduction* through the material interchange with 'inorganic nature', which is 'life-producing-life' (Marx, 1992a [1844]: 328).[2]

Consequently, in order fully to account for the specificity of labour, Marx also needed to further uncover its *immanent* more abstract determination as a mode of existence of 'life activity in general', of 'species-life' as such.

Marx's clearest rendition of this immanent natural content in the determination of human productive activity can be found in a passage from the third of the *Paris Manuscripts*, in the context of his critique of both idealism (Hegel) and (abstract) materialism (Feuerbach) from the viewpoint of what he calls at this stage 'consistent naturalism or humanism', which is the 'only [perspective] capable of comprehending the process of world history' (1992a [1844]: 389):

> Man is directly a natural being. As a natural being and as a living natural being he is on the one hand equipped with natural powers, with vital powers, he is an active natural being; these powers exist in him as dispositions and capacities, as drives. On the other hand, as a natural, corporeal, sensuous, objective being he is a suffering, conditioned and limited being, like animals and plants. That is to say, the objects of his drives exist outside him as objects independent of him; but these objects are objects of his need, essential objects, indispensable to the exercise and confirmation of his essential powers. (Marx, 1992a [1844]: 389–90)

As with any living natural being, the relation of the human being to nature consists of a process whereby the individual actualizes its own bodily 'vital' powers (i.e. what a few years later Marx and Engels in the *German Ideology* (1976 [1845]) would term its 'corporeal organization'), with the purpose of appropriating the objective potentialities immanent in their natural environment. This is the material process that, later in his life, Marx would refer to as the 'metabolism between man and nature' (Marx, 1976a [1867]: 133). Moreover, as with every animal life-form, this involves the material expenditure of the living individual's corporeality in order to act upon external nature in a particular fashion corresponding to its species-determination, whose end result is the appropriation and consumption of the 'essential objects' that satisfy its needs, thereby reconstituting and transforming the materiality of its bodily existence.

Thus, the defining qualitative attribute of the living individual lies in the material potential to self-reproduce; that is, to posit through their own activity the renewal of the conditions for their continued existence as an 'objective natural being'. This material potential for self-reproduction is expressed in their *cognitive capacity*, which is constituted by their vital, living power to recognize the mutual 'affinity' between their own material potentialities and those of their objective environment (Iñigo Carrera, 2007: 43–4). Through the exercise of their cognizing activity, the living individual has therefore the power to satisfy their own needs by organizing and regulating the actual unfolding of their bodily action upon external nature. On the basis of all these determinations, the living individual is determined as *subject*, they are endowed with *subjectivity* (as opposed to the sheer objectivity of non-living forms of nature).

According to Marx's discussion in the *Paris Manuscripts*, in its simplest expression the distinctiveness of the human species-being (hence of *human* subjectivity proper) appears at first sight to involve a merely *quantitative* difference from animal life-forms, one *of degree of universality* in the *scope* of its appropriation of inorganic nature (Marx, 1992a [1844]: 329). However, Marx stresses that underlying this quantitative difference there is a *qualitative* specificity in human subjectivity, which he finds in the fact that the human being has *conscious life-activity* (1992a [1844]: 328). Hence, Marx saw the specifically *human form* of the natural life-process in the fact that human beings regulate the appropriation of the objective powers of the natural environment through the organization of the externalization of their own vital powers by means of *thought*, *conscious cognition* or *knowledge*, that is, by *ideally* appropriating nature's potentialities as the necessary first step before its real appropriation through the effective unfolding of action. In other words, human beings are not simply bearers of subjectivity, but also *know or recognize themselves as subjects* in the process of affirming their species-powers, thereby 'making life activity itself an object of [their] will and consciousness' (1992a [1844]: 328).

Now, as Marx and Engels clarified some years later in *The German Ideology* against the backdrop of the Young Hegelians' 'empty phrases about consciousness devoid of any material premises' (1976 [1845]: 37), this conscious subjectivity is but the expression of the fact that human beings 'can be distinguished from animals by consciousness, by religion or anything else you like', but 'they themselves distinguish themselves from animals as soon as they begin to *produce* their means of subsistence' (1976 [1845]: 31). In other words, in this text Marx and Engels want to throw into relief the *immanent material connection* between the determination of consciousness as a distinctively human attribute and the fundamentally *mediated* character of the human being's life-process. Their emphasis on the production of means of subsistence is therefore meant to stress the distinctively *transformative* mode of the process of metabolic exchange with nature as the *simplest content* of the human species-being which takes on a more developed mode of existence in the *form* of their conscious and voluntary being.

As Sayers (2007: 434) aptly emphasizes, the primordial and most general determination of human labour, which qualitatively distinguishes it from the broadly *unmediated* character of the life-process of non-human animals, is to be 'form-giving' life-activity.[3] Thus, in *The German Ideology* Marx and Engels stress that the conscious and voluntary form taken by the human life-process is not a dogmatic 'philosophical postulate' but a determinate, 'empirically verifiable', objective natural expression of the 'corporeal (or bodily) organization' of 'living human individuals and their consequent relation to the rest of nature' (Marx and Engels, 1976 [1845]: 31). Although in the latter text Marx and Engels do not 'go into the actual corporeal nature of man' (1976 [1845]: 31), it is clear, as Fracchia (2005) remarks, that this 'corporeal organization' entails, in the first place, the evolutionary emergence of the human brain as the bodily instrument whose functioning is expressed in the form of consciousness. But, in the second place, Fracchia rightly adds that it is also evident that the development of the specific configuration of the human brain has been in turn the outcome of prior evolutionary changes in the corporeal organization of hominids eventually leading to the *Homo Sapiens*, all of which made possible the transformative or productive character of its mode of life based on labour: opposable thumbs, bipedalism, binocular vision, etc. (Fracchia, 2008: 39). This emphasis on the 'corporeal roots' of human beings and their subjectivity might seem at first sight a self-evident triviality, yet it is not if, as Fracchia (2017) notes, familiarity ends up breeding neglect, as is arguably the case in much contemporary social theory. Thus, the relevance of this reminder about the natural and evolutionary dimensions of human subjectivity can be said to transcend the historical context of Marx and Engels's polemic against the Young Hegelians and has become very contemporaneous.[4]

In this sense, consciousness is the most potent evolutionary development that eventually emerged to regulate the greater cognitive complexity entailed by the growing instrumental, spatial, temporal and personal separation between the initial action that sets into motion the process of human metabolism with nature and its end result, which is achieved with the material reproduction of the corporeality of an individual human being through the consumption of the product of labour (Iñigo Carrera, 2007: 45). In other words, as available paleoanthropological scientific evidence confirms, consciousness evolved as a result of the *increasingly mediated character* assumed by the forms of practical transformative activity of our *hominid* predecessors, and which eventually led to the emergence of strictly human (in the sense of the modern *Homo Sapiens*) modes of life.[5]

In light of the determinations of human labour unfolded so far, we can now proceed to further specify the way human beings distinguish themselves from animals and why they do so. As we have seen, according to Marx the simplest difference consists in the capacity to produce its means of subsistence. This is the specific determination of the human life-process seen, as it were, from a synchronic point of view. However, that simple specificity manifests itself also in a further determination when grasped from a *developmental* perspective. That is, when seen from the perspective of the way in which human beings *expand* the potentialities of their process of metabolism in contradistinction to other animal life-forms (Iñigo Carrera, 2007: 44). Due to their more limited ability to modify external nature to make it apt to satisfy their needs, non-human animals can only develop their capacity to appropriate natural forms by means of a genetically induced mutation of their own corporeality, which allows them to *adapt* to what they confront as *given* conditions of existence, i.e. by *evolving* into another species (Fracchia, 2017). Conversely, in having developed the capacity to alter their life conditions through conscious productive practice, human beings have also *qualitatively* 'sublated' the way in which, as living subjects, they expand the powers of their metabolic process with nature. The key to those developmental dynamics of the natural life-process no longer only resides in further biological speciation through the modification of bodily organs. Instead, humans can 'change their own nature' (Marx, 1976a [1867]: 283) through the development of the transformative powers of their life-process, i.e. *of the productive powers of their own labour*. The development of the 'material forces of production', Marx thus concluded, becomes determined as the most general *qualitative content* that gives underlying unity to the 'history of humanity' (Marx and Engels, 1976 [1845]: 43).

As a result of these specific developmental dynamics, human beings can not only universally expand the areas of nature which become determined as concrete forms of their activity, but they can also complexify the mediations involved before the final appropriation of natural objects as use-values that are immediately apt for the satisfaction of human needs, thereby consuming properly 'human objects'. In other words, they can extend and deepen the 'humanization of nature' (Marx, 1992a [1844]: 329, 352–4; Marx and Engels, 1976 [1845]: 39).

Furthermore, this applies to all kinds of human need, whether they spring from the 'stomach or the imagination' (Marx, 1976a [1867]: 125). Thus, the materiality of the satisfaction of human needs involved in the 'metabolic exchange with external nature' by means of labour does not only refer to 'those of the individual … reduced to a natural subject' (Marx, 1993 [1857–8]: 528), but also to 'historic needs … created by production itself, social needs' (Marx, 1993 [1857–8]: 527). Moreover, they are not just of a 'physical' nature (Marx, 1976a [1867]: 275, 341) but also include 'intellectual and social requirements' whose extent and number 'is conditioned by the general level of civilization' (Marx, 1976a [1867]: 341). In a similar vein, the product of labour to be consumed comprises not only 'goods' but also so-called 'services', whose result may not be a 'useful object' but still involves a *material* 'useful effect' which also changes the form of external nature (Marx, 1978 [1885]: 135). As Sayers (2007: 444–8) perceptively notes, the same could be said about the 'symbolic' and 'affective' content of use-values that is so central to contemporary theories of 'immaterial labour' (Hardt and Negri, 2005). In *all* cases, the satisfaction of those needs is the necessary material form for the reproduction and/or expansion of the productive powers of individuals (Marx, 1993 [1857–8]: 717fn), that is, of the 'aggregate of those mental and physical capabilities existing in the physical form, the living personality, of a human being, capabilities which he sets into motion whenever he produces a use-value *of any kind*' (Marx, 1976a [1867]: 270, *emphasis added*; see also 717). In other words, there is no satisfaction of 'physical' and intellectual needs through the consumption of use-values which is not determined as an inner moment of the development of the specific attributes or powers of the human being as an essentially *labouring* or *productive* subject, i.e. of the development of the 'human mastery over the forces of nature, those of so-called nature as well as of humanity's own nature' (Marx, 1993 [1857–8]: 488).

By virtue of these determinations in their synchronic and diachronic unity, Marx argued in an obvious 'activist' twist to Feuerbach's (2008 [1841]) 'contemplative' argument in the first chapter of his *The Essence of Christianity*, the human being does not simply *have* a determinate species-character but actually *is a species-being*, 'a being which treats the species as its own essential being or itself as a species-being' (Marx, 1992a [1844]: 329).[6]

At this juncture, it might be worth remarking that this early discovery of the specific determination of the human being as a *productive* subject, or of human individuality as an expression and mode of development of her/his *labouring activity*, would remain unaltered throughout the rest of Marx's works. The exposition by the 'mature Marx' of the general determinations of the labour process in chapter 7 of *Capital*, Volume I, does not involve any substantive change in comparison with the discussion of the human species-being by the 'young Marx' of the *Paris Manuscripts* (1992a [1844]) or by Marx and Engels in *The German Ideology* (1976 [1845]). Labour is thus defined as follows:

> A process between man and nature by which man, through his own actions, mediates, regulates and controls the metabolism between himself and nature. He confronts the materials of nature as a force of nature. He sets into motion the natural forces which belong to his own body, his arms, legs, head and hands, in order to appropriate the materials of nature in a form adapted to his own needs. (Marx, 1976a [1867]: 283)

Additionally, what gives labour 'a form in which it is an exclusively human characteristic', transcending those 'instinctive forms … which remain at the animal level', is the fact that 'at the end of every labour process a result emerges which had already been conceived by the worker at the beginning, hence already existed ideally' (Marx, 1976a [1867]: 283–4). This result, Marx continues, emphasizing the form-giving character of the human metabolic process, 'is a use-value, a piece of natural material adapted to human needs by means of a change in form' (1976a [1867]: 287), whose transformation is furthermore effected *via* 'the use and construction of instruments of labour', which, 'although present in germ among certain species of animals, is characteristic of the specifically human labour process' (1976a [1867]: 286). In sum, all the determinations of human labour as conscious, transformative life-activity are maintained by Marx in the most developed version of the critique of political economy unfolded in *Capital*.[7]

THE IMMANENT SOCIAL CHARACTER OF LABOUR AND HUMAN PRODUCTIVE SUBJECTIVITY: 'SOCIAL BEING' AND CONSCIOUSNESS

The '*fashioning* of inorganic nature' (Marx, 1992a [1844]: 328–9) in a form 'adapted to human needs' does not exhaust the intrinsically mediated character of human life-activity underpinning the necessity of its conscious form. A further mediation that adds to the complexity of the human process of metabolism lies in the necessary *social* character of productive activity (Marx, 1993 [1857–8]: 83–4). For, although human productive powers are borne by each particular individual, the development and actualization of these potentialities characterizing the species – i.e. the realization of the transformative powers of the human being – can only affirm themselves through the organic unity of individual lives, through social life. In effect, as Iñigo Carrera points out (2007: 47–8), individually borne human productive powers can only be constituted socially, that is, they can only develop as a result of the productive action of other individuals (who, for instance, have participated in the production of the use-values whose consumption resulted in the productive attributes borne by the former individual's labour-power). Moreover, the individual labourer produces use-values not solely for her/his own consumption, but for others, that is, *social* use-values. As Marx puts it in the *Paris Manuscripts*:

> We have seen how … man produces man, himself and other men; how the object, which is the direct activity of his individuality, is at the same time his existence for other men, their existence and their existence for him … Activity and consumption … in their content are social activity and social consumption. (1992a [1844]: 349)

Note, however, that this does not simply mean that human productive activity always presupposes a 'social context' within which it takes place (e.g. sociologically conceived social 'institutions' that 'structure', 'condition' or 'constrain' human 'agency'). Thus posed, the relation between the social and individual character of human productive activity is rendered completely external. This is why a few lines later, through the example of the *seemingly* isolated activity 'in the field of science', Marx throws into relief the *immanent* social character of labour as an individual action, i.e. its determination as a material expenditure of *individually borne* yet *socially constituted* corporeal powers to transform external nature, consciously, into a means for human life:

> It is above all necessary to avoid once more establishing 'society' as an abstraction over against the individual. The individual *is* the *social being*. His vital expression – even when it does not appear in the direct form of a communal expression, conceived in association with other men – is therefore an expression and confirmation of *social life*. Man's individual and species-life are not two *distinct things*. (1992a [1844]: 350)

Thus, the organization and regulation of the individual process of human metabolism with external nature acquires an additional qualitative and quantitative cognitive complexity. It needs to affirm itself as an organic 'element of the total labour of society' (Marx, 1976a [1867]: 165), i.e. to posit its underlying *general social unity* through its material articulation with the life-processes of other human individuals. To put it differently, the production of life through the expenditure and development of the *productive powers or forces* of the human individual, i.e. a material or natural relation, takes on necessary concrete shape (and is thereby necessarily mediated) in and through *social relations*, which are therefore determined as social relations of *production*:[8]

> The production of life, both of one's own in labour and of fresh life in procreation, now appears as a twofold relation: on the one hand as a natural, on the other as a social relation – social in the sense that it denotes the co-operation of several individuals, no matter under what conditions, in what manner and to what end. (Marx and Engels, 1976 [1845]: 43)

The essential *most general* determination at stake in all social forms of the human life-process is therefore the organization of the unity of the social character of individual labours, that is, the social regulation of the allocation of the total labour of society in its different individual concrete forms in order to reproduce and expand the materiality of the productive powers of human beings. The *historically changing character* of the social relations of production is given by the specific form in which each society mediates 'the participation of the individual in general production' or the positing of 'the labour of the individual … as social labour' (Marx, 1993 [1857–8]: 171–2).[9]

On the other hand, this means that in its material condition as the specifically human capacity to organize the life-process, consciousness always entails a twofold determination as much as the labouring activity that it organizes and regulates (Iñigo Carrera, 2007: 43–9). Consciousness thereby does not simply undertake the regulation of the individual appropriation of the potentialities of external nature in order to transform it, but must also mediate the establishment of individual labour's immanent unity with the socially general metabolic process of which it is an organic element. In other words, consciousness needs to articulate the determination of individual productive activity as part of the general social division of labour. As an attribute borne by the individuality and corporeality of each human being, consciousness is thus the personal power or capacity to partake in the establishment of the unity of social labour through individual productive action, i.e. to regulate the social character of individual labour.

In this sense, consciousness, and along with it language (hence, *human subjectivity* proper), are also 'evolutionary' products of the development of the *social* character of labour:

> Language is as old as consciousness, language is practical, real consciousness that exists for other men as well, and only therefore does it also exist for me; *language, like consciousness, only arises from the need, the necessity, of intercourse with other men*. Where there exists a relationship, it exists for me: the animal does not '*relate*' itself to anything, it does not '*relate*' itself at all. For the animal, its relation to others does not exist as a relation. Consciousness is, therefore, from the very beginning a social product, and remains so as long as men exist at all. (Marx and Engels, 1976 [1845]: 44, *emphasis added*)[10]

The determination of consciousness by the social character of labour not only pertains to its natural genesis. It also underpins its subsequent modes of existence and development, so that, as Marx and Engels stress in their well-known aphoristic statement, 'consciousness [*das Bewusstsein*] can never be anything else than conscious being [*das bewusste Sein*], and the being of men is their actual life-process' (1976 [1845]: 36). Moreover, insofar as this actual life-process is *form-determined* in *historically changing* social modes of existence, so will be the concrete forms of human subjectivity that, in turn, mediate the establishment of the unity of the social relations of production through the conscious and voluntary action of individuals. In other words, all concrete social forms assumed by human conscious and voluntary subjectivity are the way in which individuals see both themselves and the historically determined modes of existence of their social relations, which are two sides of the same coin once the apparent exteriority between society and individual is overcome. Through the different forms of subjectivity, human beings therefore organize the unfolding of their individual actions as organic moments of the material reproduction of the *socially mediated* unity of their metabolic process with nature, i.e. their consciousness is always determined as 'consciousness of existing practice' (Marx and Engels, 1976 [1845]: 45).

It follows that the point of Marx's materialism is not to conceive of social being as a self-subsistent existence that externally 'causes', 'conditions' or 'functionally moulds', from such exteriority, an equally self-subsisting consciousness. Such severance and consequent external relation of social being and consciousness, with the latter floating in mid-air in an ontologically conceived 'superstructure' of society, would certainly be idealist. Analogously to the relationship between productive forces and social relations discussed earlier, the key to overcoming such dualistic representations is to grasp social being or social relations of production as the inner material and social *content*, which is necessarily realized, and therefore exists, in the *form* of the determinations of the consciousness of the human individual.[11] As Marx bluntly and succinctly puts it in the *1861–63 Manuscripts*, 'social relations only exist between human beings to the extent that they think' (1988 [1861–3]: 232). In other words, there are no social relations of production or forms of human productive practice (and, *a fortiori*, no material productive forces of labour) whose determinations could be conceived of in abstraction from (i.e. not *immanently* mediated by) consciousness. Productive powers of social labour, social relations of production and forms of consciousness constitute the indissoluble unity between the content and form of the determinations of human productive subjectivity and practice in the process of 'natural history', that is, of human labour and its historical development.

CONTROVERSIES OVER MARX'S PERSPECTIVE ON HUMAN LABOUR

A first strand of critiques of Marx's notion of labour emerged outside Marxism in the second half of the twentieth century and are of sociological or philosophical origin. Thus, Habermas (1971 [1968], 1987 [1985]) argues that Marx's conception of labour one-sidedly conceives of human practice as 'monological' or merely instrumental activity, and fails to throw into relief the constitutive 'interactional' or 'communicative' dimensions of human action. In other words, Marx is read as unable to grasp the difference between 'labour' and 'interaction' or, in Habermas' later formulation, that between 'instrumental' and 'communicative' action, which allegedly lies at the basis of the social life-process. For her part, and in a similar vein, Arendt (1998 [1958]) considers that Marx confuses or conflates the threefold distinction that constitutes the human being's *vita activa*, that is, 'labour' (as animal-like, merely biological metabolic activity with nature), 'work' (as purposeful activity that humanizes nature in a lasting, non-ephemeral way), and even more starkly, 'action' (as radically self-initiating, necessarily collective and 'public', end in itself). In light of the earlier discussion, one could argue that these critiques are predicated on a misreading of Marx's perspective on the determinations of labour (particularly serious in the case of Arendt) (Holman, 2011), insofar as they overlook the irreducible *immanent social character of productive activity*. Thus, it is these authors who actually, and wrongly, reduce labour to an asocial, purely individual material interchange with nature. As a consequence, they then need to come up with other dimensions of human action, which are therefore rendered 'autonomous' from the material reproduction process, in order for social life to attain unity. In other words, in Habermas' and Arendt's respective approaches, the intrinsic unity between the different determinations of human labour become 'fossilized' into extrinsically related 'dimensions' of human action or, worse still, into plainly distinct forms of human action.[12]

In the second place, some Marxists themselves have raised certain objections that partly take issue with (the early) Marx's own treatment of labour, insofar as it involves an 'affirmative' view of labour as the 'transhistorical' essence of human life which would be emancipated with the overcoming of capital. Instead, they put forward a negative critique of the historically specific self-mediating or ontological role of labour in capitalism, which must actually be abolished under communism. Paradigmatically, this is the case of Postone's (1996) more broadly discussed work and of the lesser-known but similar approach by Kurz and the German *Wertkritik* (Jappe, 2014; Larsen et al., 2014). More concretely in the case of Postone, he argues that whereas in non-capitalist societies 'the social distribution of labour and its products is effected by … manifest social relations', in 'commodity-determined society' (i.e. capitalism) '*labour itself constitutes a social mediation in lieu of overt social relations*' (Postone, 1996: 149–50). According to Postone (1996: 148), this socially self-mediating role of labour in capitalism in turn derives from the dual character that it acquires, by virtue of which it not only produces use-values for others as intentional activity that transforms nature in a determinate fashion (what Marx terms *concrete labour*) but also acts as a means of acquisition of the products of others. And since 'there is no intrinsic relation between the specific nature of the labour expended and the specific nature of the product acquired by means of that labour', that *historically determinate function* of labour as 'means of acquisition' must be done by abstracting 'from the specificity of … its own concrete form' and on the basis of its character as labour in general (i.e. as abstract labour) (Postone, 1996: 151–2). Social interdependence in capitalism, Postone concludes, is not achieved by means of overt social relations but specifically by (abstract) labour itself (1996: 151–2). As a further corollary, Postone (1996: 58–68) states that the 'traditional Marxist' notion of labour that sees its socially constitutive role as a generic or transhistorical determination leads of necessity to the naturalization of the capitalist form of labour and, *a fortiori*, of the alienated or objectified forms of social mediation (and concomitant impersonal forms of domination) to which the former gives rise.

Now, there are several and wide-ranging problematic and controversial issues in Postone's undeniably thought-provoking contribution; here I can only mention two which are of immediate relevance to this chapter. In the first place, and at a formal argumentative level, one could say that Postone's rejection of the generic determination of labour as the specific form of action that is socially constitutive of human subjectivity is based on a combination of terminological conflation (between 'labour' and 'abstract labour') and *non-sequitur* reasoning.[13] Leaving aside other shortcomings in his discussion of the socially mediating function of labour in capitalism,[14] all that he manages to demonstrate is that in this society the social positing of labour is uniquely established on the basis of its abstract or general character. But this does not necessarily mean that labour as such, broadly understood as human transformative activity upon nature, does not play this social function in non-capitalist societies. It might as well mean, as Marx himself argues in *Capital*, that in those other societies the intrinsic social character of individual labour is established on the basis of its particular, concrete character (Marx, 1976a [1867]: 170–1), which still is an immanent determination of the organization of social *labour*, and not of other, undetermined forms of social relations lacking in material, productive content, whatever those might be.

This leads us to a second, substantive weakness of Postone's approach. Postone (1996: 56) does not seem to disagree with Marx's view that 'the entire productive activity of man, through which his metabolic interchange with nature is mediated' (1991 [1894]: 954) 'is a condition of human existence which is independent of all forms of society' (Marx, 1976a [1867]: 133). Moreover, he concedes that 'labour, of course, has a social character in all social formations' (Postone, 1996: 150). However, on closer inspection it transpires that for Postone this *social character* is not *immanent* in the very materiality of labour. Instead, Postone submits that 'in noncapitalist societies, laboring activities are social by virtue of the matrix of overt social relations in which they are embedded', the latter being 'the constituting principle of such societies', so that the 'various labors are imbued with meaning by the social relations that are their context' (Postone, 1996: 150). The very choice of terms in Postone's formulations ('embeddedness', 'social context') betrays the irreducible externality in the relation that he posits between 'labouring activities', which are represented as a sheer material process lacking in immanent social content and, on the other side, 'manifest social relations', whose inner purpose and general unity (i.e. their *raison d'être*) is never *positively* spelt out by Postone (they are only *negatively* defined as not grounded in labour), but which are nonetheless said to impose, from such exteriority, their (self-grounded?) meaning and significance to labour and its products (Postone, 1996: 171–3).

Lastly, the other significant controversy among Marxists which I shall mention in this section concerns the essential developmental dynamic which, according to Marx, underlies and gives unity to the historically evolving modes of existence of human subjectivity, namely the development of the material productive forces of labour. In the view of certain critical commentators, this perspective can only lead to a 'technologically determinist' materialist philosophy of history, in which, the 'exogenous' development of productive forces (understood as instruments of production or as a particular 'combination' of means of production and labour-power required by a certain technique of production, i.e. in both cases as 'things') acts as the motor that mechanically engenders a linear succession of 'corresponding modes of production' in a rigid evolutionary chronological sequence. As a result, these critics conclude, the Marxian 'materialist conception' implies an 'objectivistic' view which downplays or simply ignores the role of human subjectivity and action in the development of history (Gunn, 1992). As Clarke (1980: 21–2) points out, however, a first problem with this line of thought is that such a crude 'technological determinism' is completely alien to Marx's ideas and is more a reflection of its codification into a dogmatic philosophy of history by the orthodox Marxist tradition, in particular that which was consolidated as the state ideology of the former Soviet Union.[15] More specifically, Clarke forcefully shows in his pioneering critique of structuralist Marxism, a crucial shortcoming of the orthodox reading of Marx's thought lies in the very notion of production, which the Marxist orthodoxy represented as an abstractly 'technical' process, with social relations brought down to relations of *distribution* constituted by ownership of means of production, and *extrinsically* superimposed onto the direct labour process (Clarke, 1980: 21–2).[16]

In contradistinction to this orthodox reading, we have seen that Marx's account of the determinations of the labour process involves the indissoluble and contradictory *intrinsic* unity between the material relation between human beings and nature and its socially mediated character (hence between productive forces, social relations of production and their actualization in and through the conscious practice of individuals). We have also seen that 'productive forces' do not simply belong in a world of objects or 'things' (i.e. the instruments of production), abstractly external to human subjectivity, with their mutual relation represented as mechanistic causality or functional/structural correspondence. Or rather, they do comprise the world of things but to the extent that the latter are grasped as 'products of human industry; natural material transformed into organs of the human will over nature, or of human participation in nature. They are *organs of the human brain, created by the human hand*; the power of knowledge, objectified' (Marx, 1993 [1857–8]: 706). Moreover, we have argued earlier that there is no conceivable shape of the productive forces which does not exist in and through the form-determinations of consciousness. The former's historical development is, of necessity, that of the *consciousness of human beings*, albeit materialistically grasped as essentially productive subjects. In sum, the development of the forces of production is tantamount to the development of the materiality of *human productive subjectivity*. In this sense, 'productive forces' belong in the innermost realm of human individuality and, more precisely, of the specifically human capacities or powers for conscious transformative action. So this view can hardly lead, as implied by the critical commentators referred to earlier, to an 'objectivistic' denial of subjectivity and action in the unfolding of history. What it does deny, however, is the rendition of human consciousness and will (hence of human subjectivity and action) as idealistic constructs, which can only thereby be grounded on an abstract natural freedom of the individual, and therefore deprives the very specificity of the conscious human subject that it purports to extol of any material foundation in the movement of its life-activity as a 'sensuous objective being'. By contrast, Marx's view that the development of the productive forces of labour constitutes the essential content of history uncovers the immanent (as opposed to mechanistic) material determination of human subjectivity and its conscious and voluntary activity in the social life-process.[17]

Notes

1 In this chapter, and following Marx's usage in his later writings, I will use the term 'labour' (*Arbeit*) as denoting human *productive activity* in general, that is, as broadly as possible as 'formative activity' upon nature (Sayers, 2007). The terminology was different in the early writings such as the *1844 Paris Manuscripts* or the *German Ideology* (Arthur, 1986: 12–19). In these latter texts, the term 'labour' was sometimes equated with *alienated* productive activity under the rule of capital, whereas 'self-activity' or 'practical human activity' tended to denote the conscious transformation of nature by human beings. This is the reason why it is possible to find various passages in the early writings in which Marx states that human emancipation and the supersession of alienation entail the 'abolition of labour' (e.g. Marx and Engels, 1976 [1845]: 87).

2 On the Hegelian lineage of this perspective on the determinations of the natural life-process, as well as on the 'organic/inorganic nature' distinction, see Foster and Burkett (2000).

3 As Sayers (2007) also notes, this broad view of labour as form-giving activity upon nature can be traced back to Hegel (cf. 1977 [1807]: 118; 1991 [1821]: 56, 196–7). This is not to deny that other species are capable of 'objectification' (albeit mostly instinctually rather than intentionally), in the sense of 'transforming what is naturally given into worlds made in the image of their own needs and capacities' (Fracchia, 2005: 44); a phenomenon of which Marx was perfectly aware (Marx, 1976a [1867]: 283, 1992a [1844]: 329). However, not only is the transformative power of non-human animals very limited and one-sided (Fracchia, 2017), but its human forms entail not just a quantitative difference (i.e. one of degree) but a qualitative self-differentiation of the natural life-process beyond its *merely* 'animalistic' modes of existence (and this includes whatever incipient 'mental' powers for 'reasoning' could be found among non-human animals).

4 In effect, as McNally suggests (2001: 79), with the advent of post-modernism as the dominant form of self-proclaimed radical social thought, any reference to natural determinations in human life is usually seen as an old-fashioned 'modernist prejudice'. On the other hand, the question gets even more compounded by the ideological use of evolutionary theory made by 'sociobiology', which naturalizes existing forms of domination by locating their source in our genes (McNally, 2001: 79). However, the post-modern reaction that stresses the 'cultural production of the body' could be said to be its mirror image, substituting a 'sociological/cultural' reductionism for a biological one. In other words, the mere reversal of the terms of the relationship between nature and society does not do away with the inevitable externality of their connection thus conceived. Instead, the challenge for a critical materialist standpoint is to overcome the *dualism* in the relationship between nature and society, which means recognizing their 'unity-in-difference'.

5 See on this McNally´s stylized but well-informed account of the evolution of human thought and language, which shows that crucial in this process has been the 'use of intermediary objects (such as tools) to affect the environment to determined ends' (2001: 93).

6 An insightful and pioneering discussion of this point can be found in Colletti's *Marxism and Hegel* (1973 [1969]), who also traces the intellectual lineage of Marx's discussion of the human being as a species-being further back than Feuerbach's (2008 [1841]) *The Essence of Christianity* (Colletti, 1973 [1969]: 234–43). Of particular significance is Colletti's discussion of the qualitative specificity of human beings as natural living subjects vis-à-vis other natural life-forms, which gives them the character of a *genus*, vis-à-vis the rest of the animal *species* (Colletti, 1973 [1969]: 244–6). For this reason, as the translator of *Marxism and Hegel* rightly notes, 'generic-being' is actually a more adequate English rendition of the German *Gattungswesen* (Colletti, 1973 [1969]: 233, fn. 76).

7 For a contrary reading, see Wendling (2009: 62–6, 83–8, 96–7), who submits that Marx changed his views (albeit with ambiguity), from an initial 'vitalist' perspective in which labour was seen as the self-actualization and form-giving objectification of human subjectivity in the natural world, to an 'energeticist paradigm' adopted from the thermodynamic science of the scientific materialists.

8 Thus, social relations of production are not for Marx simply 'economic' but encompass the unity of the human life-process in all of its moments (Marx, 1977 [1847]: 212).

9 That is the gist of Marx´s oft-quoted letter to Kugelmann (Marx, 2010 [1868]: 68).

10 Again, as McNally (2001: 100–3) reports, contemporary scientific evidence from evolutionary theory validates Marx and Engels' insights on the qualitative specificity of the social character of tool-making (or 'co-operative heterotechnic toolmaking' as this author puts it) as a distinctively human phenomenon, on the one hand, and on its intrinsic material connection with the emergence of consciousness and language, on the other.

11 In this sense, Marx's whole discussion of the fetish-like character of the commodity could be seen as the *simplest* expression of the historically specific mode of existence of the immanent unity between productive forces of human labour, social being and forms of consciousness in the capitalist mode of production (Starosta, 2017). That is why Marx can claim *both* that value is the thing-like form of existence of social relations between people (Marx, 1976a [1867]: 166) *and* that the reduction of the 'material thing to the abstraction, *value* … is a primordial and hence unconsciously instinctive operation of their brain' (Marx, 1976b [1867]: 36).

12 For an early Marxist reply to Arendt, see Suchting (1962). A more recent methodologically minded Marxist assessment of the weaknesses of Arendt's threefold distinction can be found in Holman (2011). For a Marxist critique of Habermas along the lines suggested above, see Reichelt (2000), Elbe (2017) and Sayers (2007: 446). Postone (1996: 231) also develops an insightful Marxist critique of Habermas, albeit based on his idiosyncratic rejection of the generic constitutive role of labour in the development of human subjectivity.

13 This terminological conflation between 'labour' and 'abstract labour' is also key to the German *Wertkritik*'s 'Manifesto against Labour' (Krisis Group, 1999).

14 For instance, he ambiguously and interchangeably posits *labour* or the *product of labour* as performing the function of social mediation (Postone, 1996: 150).

15 The standard source for this codification is Stalin's *Dialectical and Historical Materialism* (2013 [1938]). However, a more recent and methodologically more sophisticated and cogent statement of the orthodox 'traditional historical materialism' can be found in Cohen (2001 [1978]).

16 As Clarke notes, this notion of production is characteristic of Althusser's early work as well.

17 For a substantiation of this general methodological argument through a detailed exposition of the developmental dynamics of the historically specific contradictory unity between materiality and social form of capitalist production (i.e. *the real subsumption of labour to capital*), which also underlies the immanent ground of modern forms of subjectivity (both capital-reproducing and capital-transcending), see Starosta (2016).

'If "Marxists" would only read Marx': The significance of Simon Clarke's Marxism

Greig Charnock

Guido Starosta
Universidad Nacional de Quilmes, Argentina

Abstract
Simon Clarke was an original and consistent Marxist thinker. From an early stage in his career, he independently developed a cogent, non-dogmatic reading of Marx's work that ran against the grain of the dominant variants of Marx of his day. In this piece, we delineate the main features of Clarke's Marxism through a reading of an early essay, first drafted in 1970. We highlight his critique of ideology, his focus on the forms through which the social relations of production appear and his insistence on the unity of theory and history – the conviction that the class struggle is expressed in the concrete movement of history. These features would form the bedrock of his truly significant contribution over five decades.

Keywords
class struggle, critique of Althusserian structuralism, ideology, Marxism, production

In 1970, aged just 24 years, Simon Clarke penned a scathing critique of the structuralist Marxist philosophy of Louis Althusser. Althusser was at that time a towering presence among Western European Left intellectuals. Over the next decade, and to an extent

Clarke later admitted he was naïve to not have foreseen,[1] Althusser's project to expunge Marx's work of its 'humanist' content would go on to exercise even greater intellectual and political influence, including among various forerunners of what would become post-structuralism. Yet in that essay, which bristles with antipathy towards Althusserianism and its acolytes from the get-go, Clarke appealed to readers to resist the pull of the prevailing current of Marxist thought. Read Marx for yourself and with an open mind, he implored. This had been Clarke's own instinct. His attentiveness to 'what Marx says, *and what Marx says he is saying*' (Clarke 1980: 27) shines through the pages of that early essay. And it had paid off. Even at that relatively young age, his grasp of Marx's method and of the critique of political economy was impressively accomplished and full. The result was a veritable tour de force, a devastating indictment of the theoretical inconsistencies of Althusserian structuralism, its dogmatic inability to break with Stalinism and its affinities with bourgeois sociology.

We begin our tribute to Clarke with reference to this early essay in order to illustrate some of his most indelible and impressive personal traits: his humanity, his intelligence, his scholarly tenacity, his fierce independence of mind and his commitment to the intellectual and political project Marx bequeathed to us.[2] But we also want to acknowledge the originality and potency of Simon's contribution back then, and in recognition of how his reading of Marx *for and by himself* would form the solid and consistent basis of the even more impressive contribution he would make in the decades that followed. Given the historical distance of our present moment from that of the early 1970s, but also the degree to which the reading of Marx Clarke laid out in that essay is today the accepted vernacular among very many proponents of (what we might variously term) Marxist critical theory, open Marxism, form-analytical Marxism, or even the 'CSE tradition', it is perhaps easy to underestimate the originality and significance of Clarke's Marxism. In what follows, we point to just a few fundamental and consistent features of his approach, which he outlined himself in a few pages of that early essay – features to which he would adhere in subsequent decades, influencing myriad others, and cementing his own legacy in the process.

First, Clarke rejected as ideology *any* approach to understanding capitalist production as a mere technical question of the 'economic' production of use-values onto which juridical relations and questions of distribution and ownership are superimposed. In Clarke's (1980) reading, Marx had precisely revealed any such approaches to be forms of bourgeois ideology in that they eternise the capitalist mode of production by making the '"factors of production" . . . appear as relations already inscribed in the technical structure of the material production process' (p. x). For Clarke, on the other hand, relations *of* production do not come down to relations *in* production. This is a crucial, substantive point: for Marx, and therefore for Clarke (1980), '*the primacy of production in the historical development of a differentiated totality*' (p. 52) is fundamental. Both recognised that the production of life through the expenditure and development of the productive powers or forces of the human individual (i.e. a material or natural relation) takes on necessary concrete shape (and is thereby necessarily mediated) in and through social relations, which are therefore determined as social relations of production. So:

> Production is . . . as a process which is indissolubly social and material, *production both of material products and of social relations*. Moreover, this unity is not a harmonious unity, at least in a class society, but is a *contradictory unity*: the *contradictory unity of the forces and relations of production.* In a capitalist society this contradictory unity exists in the specific historical form of the contradiction between production as *the production of value and as the production of use-values*. (Clarke 1980: 18)

It was precisely this insight, Clarke argued, that Althusserianism and its assault on humanism and the alleged Hegelianism of the so-called early Marx sought to quash (see Pascual and Ghiotto in this forum). By developing a structural 'science' of capitalism's economic laws (related only relatively-autonomously to the 'political' sphere), Althusserianism reaffirmed its own status as ideology, as Clarke's critique laid bare. And it was this insight that also informed Clarke's repudiation of any moral critique of the 'unfair' distribution of assets, revenues or power among classes or 'factions', even as advanced by so-called neo-Marxists.

This first feature alone shows just how pioneering Clarke's reading of *Capital* was, and it is worth throwing into relief the more specific intellectual context of his intervention at that time. On the one hand, the efforts of most Marxist economists were geared towards the mathematical reduction of prices to quantities of labour (the 'transformation problem') in an attempt to 'logically prove' the fact of exploitation in capitalism. On the other hand, precisely inspired by Althusserianism, the attention of the great majority of Marxist sociologists was mainly focused on a one-sided and narrowly conceived concern with direct exploitation and domination through 'the interpersonal relation' between 'labourer and owner of means of production' (Clarke 1980: 61). By contrast, although this aspect would become more prominent and central in his later books from the 1980s like *Marx, Marginalism and Modern Sociology* or *Keynesianism, Monetarism and the Crisis of the State* (see Burnham, Bonefeld and Fairbrother in this forum) already in this early article it is possible to discern that, for Clarke, what set the Marxian *critique of political economy* apart from bourgeois social science was its discovery of the fetishistic constitution of value, money and capital as historically specific, alienated, objectified forms of social mediation in the capitalist mode of production.

Second, then, Clarke's own Marxism was attentive to how the general determination of the contradictory development of the productive powers of the human individual is expressed in the concrete, historically changing character of the social relations of production: a 'specific and determinate historical process by which social relations are subsumed under the dominant relation of production and so are determined as developed forms of that relation' (1980, p. 19). In other words, Clarke's Marxism homed in on *social form*, and his contribution to what might now be termed 'form-analytical Marxism' is significant indeed. The insight that 'social relations are not technical relations but are the social basis of *both* the "economic community" and "its specific political form"' (Clarke 1980, p. 72) formed the bedrock for his highly influential form-critique of the state (see Pascual and Ghiotto in this forum) and of money, as well as of forms of ideology in institutional academia (of sociology and economics) and of paradigms of macro-economic policymaking (Keynesianism and monetarism). Clarke (1980), like Marx, understood that

> the social relations of production appear in specific economic, political, and ideological forms, and their determination as moments of the 'relations of production in their totality' can only be through their historical subsumption under the dominant relation of production in the development of the contradiction on which that relation is based. (p. 20)

The task of Marxism, therefore, is to engage in concrete analysis of 'the *forms of domination* of social relations by the capital relation and the *specific limits* of that domination' (Clarke 1980: 20). This is the red thread that runs throughout his subsequent work on the state, money, crisis, economic policymaking and industrial relations.[3]

Third, and consequently, Clarke was disinterested in the elaboration of abstract concepts or 'laws' – whether 'interpreted in the Hegelian sense of the dialectical development of the Idea or in the positivist sense of the deductive elucidation of the fundamental postulates of the theory' (Clarke 1980: 20). Rather, his analytical gaze was fixed, laser-like, upon 'real human history' (Clarke 1980: 20), which necessarily develops through the socially constituted and situated (antagonistic) subjectivity and action of concrete individuals – in other words, upon the concrete unfolding history of experience of the working class and its struggle against capital. This insight meant that Clarke never lost sight of the need to maintain the integrity of the dialectic of theory and history, of 'thought and reality' (pp. 45–46), always resisting any epistemological temptation to formulate and promulgate so-called laws of historical development in abstraction or in separation from what is going on in the real world and with the class struggle specifically. Accordingly, Clarke (1980) was unwavering in his view that 'the fundamental class relation of capitalist society' is a 'total social relation' which is expressed in the differentiated forms which comprise the unity of the circuit of capital as a whole (p. 62). Moreover, 'this relation cannot be reduced to the economic forms in which it appears' (Clarke 1980: 62) but is also expressed in differentiated political and ideological forms. And so, therefore, the class struggle through which the relations of production necessarily develop is expressed in the concrete movement of history:

> In a class society [the relations of production] are differentiated class relations, and their development, under the impact of changes in economic conditions, and subject to the constraint of those conditions, is the development of a multi-faceted class struggle. This struggle is not, however, something divorced from production, located in some relatively autonomous political instance, taking the whole social formation as its object. *The class struggle is the form of development of the developed forms of the relation of production, an omnipresent economic, political, and ideological struggle*. (Clarke 1980: 72–73)

It follows, then, that for Clarke the organised working class – rather than new social movements, 'humanity' or the 'multitude' – is indeed the revolutionary subject (though he arrived at this conclusion via a non-orthodox route and in such a way that he never saw fit to endorse any official Party of/for the working class).

These are the enduring features of Clarke's Marxism that were already integral to his critique of Althusserianism in the early 1970s. That early essay showcased Clarke's own distinctive potency as a (then young) Marxist: confidently, authoritatively and independently expounding a non-dogmatic version of Marx that still impresses. Today, we remember Clarke for the clarity, originality and consistency of his work that would follow over subsequent decades; as a source of education and inspiration; and as a lodestar for very many other contributors to *Capital & Class* these last 50 years. Thank you, Simon.

Notes

1. Hence, he opted not to publish his essay until a decade later (Clarke 1980). The main title of our tribute is taken from the latter (Clarke 1980: 27).
2. Those of us who were fortunate to know him personally can also attest to his generosity as an academic mentor and colleague, and his warmth as a human being.
3. It should also be acknowledged that Clarke saw the ultimate limit of these forms of domination as obtaining at the scale of the world market, making him an advocate of the view that the capitalist mode of production is global in content and national only in form – another distinguishing feature relative to most of his peers.

Guido Starosta teaches the history of economic thought at the National University of Quilmes, Argentina. He was supervised by Simon Clarke while completing his doctoral research at Warwick University in the early 2000s. This research later appeared in the book *Marx's Capital: Method and Revolutionary Subjectivity* (Brill, 2016). Email: guido.starosta@unq.edu.ar

CHAPTER 4

The Commodity Form and the Dialectical Method

Introduction

In the Preface to the First Edition of *Capital*, Marx makes evident that he was fully aware of the complexity entailed by the first steps in the critique of political economy. Thus he states:

> Beginnings are always difficult in all science. The understanding of the first chapter, especially the section that contains the analysis of commodities, will therefore present the greatest difficulty.[1]

The endless debates over the real meaning and implications of Marx's discussion of the commodity form seem to suggest that, if anything, Marx's warning actually fell short of the real difficulties at stake. And whether it is explicitly acknowledged or not, it is clear that the diverse readings of Marx's critique of political economy entail different political implications.[2] In fact, it could be argued – and, hopefully, this chapter and the ones that follow will substantiate this claim – that those 'minutiae', which the discussion of the determinations of the commodity form 'appear to turn upon',[3] are of paramount importance for the conscious organisation of the revolutionary action of the proletariat. This is shown not only in Marx's insistence on the impossibility of correctly grasping the determinations of those more abstract social forms from the bourgeois standpoint of political economy,[4] but also in the central role they played in his critique of the ideological representations of them coming from the working class movement itself, e.g. Proudhonian socialism.[5]

[5] See Clarke (1994) and Shortall (1994) for good reconstructions of Marx's critique of Proudhonian socialism based on the latter's misunderstanding of the nature of the commodity and money forms. Thus, the gist of Marx's critique of Gray's proposal to preserve private commodity production while replacing the money form with labour time certificates issued by a national bank, comes down to the latter's inability to comprehend the immanent necessity of the value of commodities to take on the independent form of money (see Elson 1979b, pp. 135–6). Similarly, in the *Grundrisse*, Marx ridicules Darimon's proposal of abolishing the privilege of money (that of being directly exchangeable for all commodities) by making 'by decree'

It is my view that this diversity in the ways in which Marx's followers have read the ideal reproduction of the determinations of the commodity form contained in *Capital* is closely connected to the varied methodological perspectives from which those authors have attempted to grasp the former. In other words, those different interpretations of the actual *content* of the first section of *Capital* express different understandings of the very *form* of scientific knowledge unfolded in that book. Seen the other way round, and this is the fundamental issue to be discussed in this chapter and the next, I would argue that only on the basis of a sound comprehension of the dialectical method can the implications of Marx's investigation of the commodity form be uncovered in all their plenitude.

The need to reconsider Marx's presentation of the commodity form in Chapter 1 of *Capital* through a reassessment of his dialectical method (in particular, its connection to Hegel's *Science of Logic*) has been widely recognised by a growing number of scholars. In effect, the last twenty to twenty-five years have witnessed a renewed interest in Marx's dialectical method and its implications for value theory.[6] However, despite all the light that these works have cast on the form of Marx's argument, they have been mainly focused on the *synthetic* aspects of Marx's dialectical presentation (i.e. on the exposition of the dialectical movement from the 'abstract to the concrete'). In this sense, it could be argued that this literature has glossed over two further fundamental aspects of Marx's dialectical method, which I have discussed in the previous chapter. First, those works have not sufficiently thematised the peculiar role of the *phase of analysis* in Marx's dialectical investigation generally and in his presentation in *Capital* in particular. Second, they have not paid sufficient attention to the *specific form of the analytical process within dialectical thought*.[7] My aim here, therefore, is to fill these gaps in the literature.[8]

---

all commodities directly exchangeable (Marx 1993, p. 126). In all these cases, the common thread of the Marxian critique lies in the incapacity of those authors to grasp the necessary inner connection between the commodity and money forms.

[6] See, among others, Murray 1988; Smith 1990a; Moseley 1993; Moseley and Campbell 1997; Arthur 2002b; Albritton and Simoulidis 2003.

[7] The distinction between analysis (in the sense of dissection of the 'whole' into 'parts' or 'identification of differences') and synthesis (in the sense of reconstitution of the 'unity' of the whole) is not peculiar to dialectics. As I argue below, what sets the latter apart from formal-logical methodologies is the specific *form* taken both by the analytical and synthetic processes in dialectical thought. Zelený provides a concise discussion of the different meanings of analysis and synthesis in science and philosophy, which also traces back their intellectual lineage (see Zelený 1980, Chapter 10).

[8] These other aspects have not been entirely absent in the literature. However, they came up in

The main purpose of this chapter is to provide a methodologically minded critical reading of Marx's argument about the determinations of the value form of the product of labour in the first chapter of *Capital*. Through this reading, I shall substantiate the claim made in the first part of the book that *Capital* crystallises the positive deployment of the methodological insights gained by the 'young Marx' through his critique of Hegel, the Young Hegelians and Proudhon. In other words, I shall show that *Capital* contains Marx's dialectical method, as discussed in the first part, concretely set into motion for the intellectual reproduction of capitalist social forms. While this latter statement is true of the book as a whole (or, at least, to its first volume, the only one that Marx prepared for publication), the detailed examination of the structure of the first three sections of Chapter 1 is of particular significance. In effect, the exposition of the determinations of the commodity form contained there is, arguably, the most paradigmatic place where he presented the concrete workings of his dialectical method of research in the indissoluble unity of its analytic and synthetic stages.[9] On these grounds, additionally, I will try to show that many of the confusions and misunderstandings among both followers and critics of Marx spring from an inadequate grasp of the dialectical structure of Marx's exposition.

Finally, this close examination of the expositional structure of the first three sections will set the stage for the discussion in the following chapter of this book, in which I discuss Marx's presentation of the fetish character of the commodity. As will became evident later on, only by properly grasping the precise content and formal structure of the first three sections of Chapter 1 of *Capital* can the specific object of exposition and systematic significance of the section on 'commodity fetishism' be fully appreciated.

---

the debate among 'new dialecticians' relatively late (Murray 2002; Reuten 2000) and have not been pursued any further until recently (see Reuten 2014, who does address in great detail the connection between analysis and synthesis, and that between inquiry and presentation, in systematic dialectics). See also Brown et al. (2002) for a discussion of some of these issues through a comparison between critical realism and systematic dialectics. Be that as it may, it is my view that compared to the light thrown on the synthetic aspects of Marx's method of presentation, the nature of the relation between analysis and synthesis in the presentation, and the way in which this relates to the formal determinations of the dialectical inquiry, have not been explored with the same degree of clarity.

[9] Iñigo Carrera 2013.

Inquiry and Presentation, Analysis and Synthesis: On Some Controversies over the Initial Passages of Marx's Argument in *Capital*

In *Capital*, Marx puts into motion the discoveries which allowed him to overcome the limitations of his early account of alienated labour and its supersession. In contradistinction to the *Paris Manuscripts*, and as he clearly states in the *Marginal Notes on Adolf Wagner*, he takes as a point of departure neither the concepts of political economy nor any concept whatsoever,[10] in order thereby to discover alienated labour as their presupposition. As the title of his most important work denotes, the subject whose determinations the dialectical investigation proceeds to discover and present is *capital*, which, as the alienated subject of social life becomes 'the all-dominating economic power of bourgeois society' and must therefore 'form the starting point as well as the finishing point' of the ideal reproduction of the concrete.[11] In this sense, Marx's exposition in *Capital* does not advance towards the discovery of alienation, but instead starts from what the dialectical inquiry revealed as its most abstract and general form.[12] He starts with the immediate observation of the simplest *concretum* in which the alienation of labour is expressed in order to develop the real determinations specific to this social form.[13] As has now been widely acknowledged, this starting point is not an ideal-typical – or worse, historically existent – simple commodity-producing society, as in the orthodoxy derived from Engels and popularised by authors such as Sweezy and Meek.[14] In Marx's own words, he starts with the commodity as the 'economic cell form of bourgeois society'.[15]

> We begin with the commodity, with this specific social form of the product – for it is the foundation and premise of capitalist production. We take the individual product in our hand and analyse the formal determinants that it contains as a commodity and which stamp it as a commodity.[16]

[13] Marx 1975b, p. 198.

[14] Engels 1980; Sweezy 1968; Meek 1973. For a critique of the Engelsian orthodoxy on this question, see Arthur 1996, 1997 and 1998b; Backhaus 1980; Robles Báez 2000; Reichelt 1995; Weeks 1981.

[15] Marx 1976g, p. 90.

[16] Marx 1976c, p. 1059.

However, Marx's presentation does not directly start with the essential determinations of the commodity form, but rather starts from the immediate observation of an individual commodity in its outward appearance.[17] In a presentation which will prove full of 'metaphysical subtleties and theological niceties',[18] Marx shows that what determines the commodity as a form of social wealth is not only that, as any product of labour, it possesses a use value, but that the latter acts as the material bearer of a second attribute, namely, exchange value. The further analysis of the commodity reveals that exchange value is actually the form of expression of a content distinguishable from it – the value form, or the attribute of general exchangeability of the commodity – the substance of which resides in the abstract labour congealed in it, and whose magnitude is consequently determined by the socially necessary abstract labour time required for its production.

The above line of reasoning has been the subject of all kinds of objections put forward by different interpreters of Marx. As I argue below, those reservations about Marx's argument have their source in an inadequate comprehension of, or insufficient attention to, the nature of the crucial distinction between two different moments involved in Marx's dialectical inquiry and presentation, namely, the stage of analysis and that of synthesis. In particular, I think that it is confusion over these questions that lies at the basis of widespread critiques of Marx's line of argument about the determinations of the commodity form;

---

[17] Properly speaking, there is a previous step in Marx's presentation. He first starts with the form in which social wealth appears in capitalist society, namely, an 'immense collection of commodities' (Marx 1976g, p. 125), the individual commodity being its elementary form. The unfolding of the determinations behind this appearance is not completed until Volume II, where the unity of the movement of the total social capital itself, in the form of the circuit of commodity capital, is revealed as positing social wealth in the form of an immense collection of commodities (Marx 1978, pp. 174–7). The secondary literature on Volume II is remarkably limited compared to what has been written on Volumes I and III. Certainly, there has been a lot of discussion of the final part on the schemes of reproduction, misguidedly revolving around the notion of a mechanical impossibility of capitalist reproduction as constituting the limit to capital (see Rosdolsky 1986, for a survey of the early classical debates on that question). But the first part of Volume II has been generally neglected. Some of the few works available that deal in some detail with aspects of the former include: Fine 1975; Shortall 1994; Fine and Saad-Filho 2003; Arthur and Reuten 1998. On the circuit of capital, see especially the contribution by Arthur (1998a) in the latter book. More recently, David Harvey has contributed to redress the situation in the second volume to his *Companion to Marx's Capital* (Harvey 2013).

[18] Marx 1976g, p. 163.

not only by well known critics such as Böhm-Bawerk,[19] but also among some of Marx's disciples.[20] In brief, the general thrust of those objections is as follows: in *Capital*, Marx did not provide an adequate 'logical proof' that commodities have a 'something' in common and that that 'something' is congealed abstract labour.[21]

The first point at stake in this objection has already been forcefully made by other scholars, so I will refer to it only briefly. In a nutshell, the question comes down to the radical methodological difference which, as Meikle insightfully notes, separates Marx's dialectical approach to science from the formalism and atomism of bourgeois conceptions.[22] Clearly based on the latter, Böhm-Bawerk's objections came from someone who could only see science as a purely

---

[19] Böhm-Bawerk 1975.

[20] Thus both Reuten (1993, p. 107) and Arthur (1993, p. 76) agree that Böhm-Bawerk's objections to Marx's line of reasoning about abstract labour as the substance of value are justified; not because Marx is wrong in seeing abstract labour as the substance of value, but because his grounding of that point is defective from a 'systematic dialectical' perspective. This objection can actually be traced back to Hans-Georg Backhaus's groundbreaking essay of 1969, 'On the Dialectics of the Value-Form' (Backhaus 1980, pp. 99–100). A non-Ricardian, value-form critique of Backhaus (and defence of Marx's argument) can be found in Murray (2013).

[21] A good and concise account of the essence of this critique can be found in Kay (1979, pp. 48–58). See also Park 2003. Specifically, Böhm-Bawerk objected that Marx did not take into consideration common properties other than being products of labour – e.g. utility, scarcity, and so on – as possible determinants of exchange value (Böhm-Bawerk 1975, pp. 74–5). In this sense, it is worth noting that in the process of *inquiry* Marx did consider – but discarded and, hence, excluded from the *presentation* – 'utility in general' as the substance of value. This is evidenced by the following remarks from the preparatory *Manuscripts of 1861–63*: 'We have seen that the basis of value is the fact that human beings relate to each other's labor as equal, and general, and in this form social, labor. This is an abstraction, like all human thought, and social relations only exist among human beings to the extent that they think, and possess this power of abstraction from sensuous individuality and contingency. The kind of political economist who attacks the determination of value by labor time on the ground that the work performed by 2 individuals during the same time is not absolutely equal (although in the same trade), doesn't yet even know what distinguishes human social relations from relations between animals. He is a beast. As beasts, the same fellows then also have no difficulty in overlooking the fact that no 2 use values are absolutely identical (no 2 leaves, Leibniz) and even less difficulty in judging use-values, which have no common measure whatever, as exchange values according to their degree of utility' (Marx 1988, p. 232).

[22] Meikle 1985, Chapter 3.

'logical construct' and not the reproduction in thought of 'how things essentially are'.[23] Thus, with 'the characteristic empiricist gap between "truths" and the entities they are supposed to be true of',[24] he could only read Marx's initial pages as an abstract, formal process of 'logical proof'.[25] The possibility that those pages unfold the real nature and specific self-movement of a determinate content (the commodity form of the product of labour) and do not contain a formal deduction was beyond Böhm-Bawerk's formalistic field of vision.[26]

Secondly, and more important for the purpose of this chapter, at stake here is another aspect of Marx's argument in the first pages of *Capital* that has not been sufficiently or satisfactorily explored by most scholars: the specific nature and significance of the difference between the phase of analysis and that of synthesis within a dialectical exposition. This double movement in the dialectical *presentation* is not an arbitrary stylistic or rhetorical strategy introduced by Marx, but, as discussed in the first part of this book, reflects a real difference characterising the specificity of dialectical *inquiry*. The latter must involve *both* identification of the different forms taken by the subject whose determinations the dialectical investigation attempts to reproduce in thought (i.e. the analytical separation between social forms according to their relative degree of concreteness) *and* the 'tracking down of their inner connection' (i.e. the *synthetic* discovery of the immanent real necessity linking those different forms).[27] A fundamental implication follows from this: the exposition of the

---

[23] Meikle 1985, p. 80.

[24] Meikle 1985, p. 79.

[25] As Sayer (1979, pp. 94–5) notes, Althusser and Balibar (1968) and his British followers (Hindess and Hirst 1975 and 1977) fell prey to this appearance.

[26] Kay 1979, pp. 51–2. Besides, it is to be noted that Böhm-Bawerk completely missed the actual object of Marx's presentation in Chapter 1 of *Capital*, which is the commodity and not the causal determination of exchange ratios (Kliman 2000, p. 104).

[27] Marx 1976g, p. 102. Here my approach differs from that of both Murray and Reuten. The former seems simply to identify analysis with inquiry (what he calls 'phenomenology'), and synthesis with presentation (Murray 2000, pp. 36–8). Reuten does allow for synthetic moments in the process of inquiry, but only as 'provisional outlines of inseparability of phenomena' (Reuten 2000, p. 143). Moreover, although he is right to see the need for the dialectical presentation to be fundamentally synthetic, he does not fully explore the possibility that the dialectical researcher presenting the results of the inquiry may include 'stylised' moments of analysis in order to highlight the unity of the dialectical process of cognition. He only mentions this possibility in passing when discussing Banaji's argument about the twofold starting point of Chapter 1 of *Capital* (Banaji 1979, pp. 36–40; Reuten 2000, p. 158). But as I argue below, this presentational strategy plays a central role at least in

explanation proper of the necessity underlying the relations between different social forms – what would amount to a 'logical proof' in the language of formalistic methodological approaches – is not to be found in the dialectical *analysis*, but in the *synthetic* movement of the exposition. Now, since it is in the latter only that the unfolding of the real movement of determination – hence the explanation – actually takes place, the presentation of the findings of the dialectical inquiry could take, in principle, a fully synthetic form.[28] However, this is not the way Marx structured his dialectical exposition in Volume I of *Capital* (the only one he edited for publication himself); this exposition tends to include, in a 'stylised' form, brief presentations of the analytic process.[29] Since this peculiar structure of Marx's presentation of the determinations of the commodity form actually recurs throughout most of Volume I, and given that its misunderstanding has caused so many controversies among critics and followers alike, it might be worth providing further elaboration on this last point.

In a nutshell, this structure of Marx's dialectical presentation starts by taking the immediate concrete appearance of the determinate social form at stake. Through a brief analytic movement, it subsequently uncovers its inner essential determination.[30] The exposition then proceeds by synthetically unfolding the realisation of that (more abstract) determination. This stage goes on until the specific potentiality defining the essential determination of the social form

---

the whole of Volume I. Fineschi (2009) offers an interesting overview of German debates in the 1970s dealing with the connection between Marx's method of inquiry and his method of presentation.

[28] Iñigo Carrera 2008, p. 317.

[29] On the role and the pros and cons of this analytic moment in the peculiar structure of the dialectical exposition in *Capital*, Volume I, organised around presentational 'nodes', see Iñigo Carrera 2008, p. 323.

[30] Marx sometimes includes *apparent* (hence flawed) analytical paths in his exposition that are revealed to be such through a movement that leads the reader back to the unmediated starting point, that is, without making any progress towards the discovery of the underlying specific determination defining the object under scrutiny (Iñigo Carrera 2008, p. 320). The presentational role of the inclusion of these flawed analytical movements is mainly pedagogical; they serve to place more emphasis on the correct analytical path. Marx's consideration of the possibility that the particular material properties of the commodity under investigation constitute the more abstract form behind the attribute of general exchangeability is an example of this (Marx 1976g, pp. 127–8). Incidentally, it is to be noted that this is the real meaning of what Böhm-Bawerk mistakenly saw as Marx's 'method of exclusion', through which he allegedly provided a 'purely negative proof' of abstract labour as the substance of value (see Böhm-Bawerk 1975, pp. 68–9).

under scrutiny, and whose realisation the exposition is ideally reproducing, negates itself as immediately carried by that abstract social form to become affirmed as immediately pertaining to the more concrete form into which it has metamorphosed. This signals that the first presentational node has been exhausted. A new one thereby begins, but now with the more concrete form whose genesis has been traced in the former as the subject of the movement to be ideally reproduced. However, the new node does not directly start with the inner determinations of this more concrete social form but, again, with its immediate manifestation. An analytic movement therefore precedes the former.[31]

Returning to my main argument about the general aspects of this formal structure of Marx's presentation: as mentioned above, it is the exposition of the *dialectical synthesis* that reveals the 'why' of real relations. The analytic stage only separates a social form from a more abstract one, whose realised potentiality it carries within itself in the form of its own immanent potentiality. In this sense, the analytic stage is about not the *why*, but the *what*. Evidently, since the separation of social forms according to their relative degree of abstractness/concreteness ideally expresses the objective necessity (the real relations) residing in the object, and is not the product of the subjective caprice or imagination of the scientist, the mere reference to the 'what' carries implicitly some hint of the 'why'. Thus, if the dialectical analysis reveals that the value form is the concrete form in which the objectification of the abstract character of private and independent labour affirms itself as an abstract form, the separation between the two already says something about the real relation involved. But this something is no more than, as it were, a 'pointing out', an observation. The actual ideal reproduction of that inner connection – the explanation – takes place in the synthetic movement.[32]

---

[31] At this juncture, it is important to point out that, in the dialectical *inquiry*, analysis and synthesis overlap in the concrete intellectual labour of the scientist. Thus the actual activity of inquiry of the dialectical researcher involves a constant passage from phases of analysis to phases of synthesis, and therefore they do not immediately appear as distinct aspects of the process of cognition. However, they do constitute two real determinations of the dialectical method and therefore it is crucial to bear their difference in mind. And it is this real difference which appears 'in its purity' in the dialectical exposition, when the author decides to reproduce the analytical stage (whether in whole or in part) in the presentation.

[32] In his *Science of Logic*, Hegel refers to this distinction between the role of analysis and synthesis as the difference between the *apprehension* of what is and its *comprehension* (Hegel 1999, pp. 793–4). However, Hegel develops this distinction as pertaining to the 'under-

With this in mind, it is easy to understand the main reason why the criticisms levelled at Marx over his inadequate explanation of abstract labour as the substance of value in the first pages of *Capital* are not simply based on a misunderstanding about the particularities of his argument, but are completely off the mark. To put it simply, those critiques search for an explanation in the wrong place, that is, in the pages where Marx is just presenting the analytic separation of real forms, which comprise the first two sections of Chapter 1. Marx's alleged explanation of why abstract labour is the substance of value in those pages sounds unconvincing simply because it is not there. As we will see, the unfolding of this particular 'why' only occurs in section three, which discusses exchange value as the form of manifestation of value. Before engaging in that aspect of Marx's presentation of the determinations of the commodity form, let us first probe deeper into the *specifically dialectical* form of the analytical moment that precedes it.[33]

---

standing', that is, an underdeveloped form of thought. Dialectical cognition, 'speculative science' in Hegel's parlance, is for him essentially synthetic (see Caligaris and Starosta 2014).

[33] Regarding Chapter 1 in particular, this structure has been recognised by Banaji (1979) and Elson (1979a). However, they both seem to reduce the content of the synthetic stage of the presentation simply to the question of revealing exchange value as the necessary mode of expression of value, i.e. to the formal necessity of the money form. But as I argue below, the latter is precisely the moment when Marx is synthetically unfolding the necessity of privately performed abstract labour as the substance of value. Neither Elson nor Banaji explicitly address the question of where exactly the 'why' of abstract labour as the substance of value can be found. Elson in particular seems to concur with Rubin (see below) that it is actually in section 4. Murray (1988, pp. 148–9) rightly sees the structure of Chapter 1 as comprising a 'double movement' of form to content and then from content to form. However, presumably reducing the dialectical movement to the synthetic stage, he sees nothing particularly dialectical in the first movement; hence his analogy with Descartes's analytical reduction of the bit of wax to primary quality matter, i.e. a search for a 'third party' or common element. In reality, the general point about the twofold movement of analysis and synthesis in Marx's exposition had already been made by Rubin in his seminal work on the theory of value (Rubin 1972, p. 113). However, as I shall discuss below, his understanding of the way they structure the exposition is, I think, incorrect. Furthermore, although Rubin does distinguish between the analytic and the synthetic (genetic, as he calls it) stages of the presentation, he seems to restrict the dialectical method to the latter (Rubin 1978, p. 110). In this way, the specific form of the dialectical analysis vis-à-vis the analysis of representational scientific thought is overlooked.

The Phase of Analysis

In contrast to the claims of those critics referred to above, I think that in the opening pages of Chapter 1, Marx is not searching for a common property in commodities. Rather, he is searching for (i.e. not yet unfolding) the specific determination defining the potentiality of the commodity as a historical form of social wealth.[34] This potentiality Marx initially 'discovers' by looking at the use value of the individual commodity, which in capitalist societies acts as bearer of a second, *historically specific* attribute of the products of labour, namely, *exchange value*. Two things follow from this. First, inasmuch as it is materially borne by the use value of the commodity, this attribute is *intrinsic* to the commodity itself. Second, as argued above, Marx is not *trying to prove logically the existence of a common property*, but *the commodity itself*, in its immediacy, shows that it *has* that 'common property' immanent in it.

Here a problem might arise, because Marx does not explicitly say in what that second attribute of the commodity consists. He just names it (exchange value) and then directly proceeds to its analysis. I think that the reason for this is that the meaning of that attribute was self-evident in the name itself in light of its everyday usage at that time. The fact that commodities have 'exchange value' simply means that they have the *power of exchangeability*, that is, *the 'fantastic' aptitude to be transformed into a different use value without the mediation of any material transformation in its bodily existence*.[35] What immediately follows in Marx's exposition is, then, the *dialectical analysis* of this social power of exchangeability of commodities. That is, Marx proceeds to answer what is the source of this specific potentiality intrinsic to the commodity, i.e. what is the abstract form appearing in the concrete form of the power of exchangeability.

---

[34] The difference between these two forms of grasping Marx's argument in the first pages of *Capital* expresses the difference between the dialectical form of the analysis and that of representational thinking. Many authors have highlighted the distinction between the abstractions of dialectics and those of representational thought as one between 'real abstractions vs. mental generalisation' (Saad-Filho 2002) or 'empiricist abstractions vs. determinate abstractions' (Gunn 1992). 'Empiricist abstractions' have also been called 'formal abstractions' (Clarke 1991a) or 'general abstractions' (Murray 1988). However, as Iñigo Carrera (2008, p. 282) points out, what most authors have overlooked is that the difference in the respective kinds of abstraction emerges as a result of the very *form* of the process of cognition on the basis of which those abstractions are identified. My argument is that this difference in form not only applies to the synthetic or genetic phase – as is usually assumed – but *crucially pertains to the process of analysis as well*.

[35] Iñigo Carrera 2007, p. 216.

As happens with every real form, the first thing he encounters when facing the exchangeability of the commodity is its *immediate manifestation* – the quantitative relation 'in which use-values of one kind exchange for use-values of another'.[36] Thus, the first step in the analysis of exchangeability is the separation of the *content and form* of that specific attribute of the commodity, this being the only way in which one can penetrate through the concrete form in which an abstract form presents itself. Again, this is the immediate object of Marx's exposition in the passages that follow, and not the search for a 'common something' or 'third thing', the existence of which the distinction between form and content presupposes.[37] This separation between form and content reveals that the different *particular* exchange relations that a commodity establishes with other commodities are actually expressions of something else that inheres in commodities and which gives them the identical *qualitative* potentiality of *general exchangeability* in a certain *magnitude*. Once form and content of the attribute of general exchangeability are distinguished, Marx continues with the analysis of the latter, which consists in separating that form of general exchangeability from the abstract form whose necessity it carries within itself as its 'other'. The particular form that this analysis takes is, again, not the search for a common element, but the search for the determinate action which posits that specific attribute existing in commodities.[38] That action, Marx states, is a human action in one of its facets, namely, productive labour in its general character or abstract labour. Commodities have this attribute of general exchangeability as products of the abstract character of the labour objectified in them.[39]

---

[36] Marx 1976g, p. 126.

[37] In order to avoid confusions, I am not implying that the existence of a common property and exchange equivalence are not important elements of Marx's arguments. My point is that Marx is not *logically proving* the existence of a common property or that the only possible substance of that common property is abstract labour. He '*finds*' that common property immanent in the commodity (actually, its immediate manifestation), and then proceeds to its *dialectical* analysis (i.e. separation of form and content). See Kicillof and Starosta 2007a and Iñigo Carrera 2007, for a fuller discussion of why being the products of the abstract character of labour is the only reasonable determination behind the value of commodities.

[38] Iñigo Carrera 2007, p. 218.

[39] Admittedly, Marx's transition to abstract labour might seem abrupt and too unproblematic. But here it is important to bear in mind that insofar as it presents results laboriously obtained through previous research, the dialectical exposition has a fluidity which does not reflect the complexity of the real activity of analysis in the process of inquiry, in which the researcher might have mistakenly taken other analytical steps. In principle, the latter

And here there is a tricky aspect in Marx's presentation, which might have contributed to much of the confusion. Because, although at that stage of the argument he has already shown that the common 'something' is the form of general exchangeability, he does not actually *name* it until separating, in turn, that form from its content or substance.

> All these things now tell us is that human labour power has been expended to produce them, human labour is accumulated in them. As crystals of this social substance, which is common to them all, they are values – commodity values [*Warenwerte*].
>
> We have seen that when commodities are exchanged, their exchange value manifests itself as something totally independent of their use value. But if we abstract from their use value, there remains their value, as it has just been defined. The common factor in the exchange relation, or in the exchange value of the commodity, is therefore its value.[40]

Marx names that intrinsic attribute of general exchangeability which is manifested in exchange value, and which is posited by the abstract character of labour, *value*.[41] Now, in opposition to the claims of a great deal of contempor-

---

do not need to be included in the dialectical presentation, although the researcher might decide to present them in order to stress the correct analytical path that leads to the discovery of the determinate content behind a specific social form (see footnote 30 above). Hence, when considering the action that posits the form of general exchangeability of commodities, the only actions other than labour that Marx contemplates (and obviously discards) are purely natural actions. In other words, he does not consider other kinds of human action, such as exchange or subjective 'valuation' of the utility of the commodity. However, as Iñigo Carrera (2007, p. 24) points out, neither of those other human actions can explain the *two* features that, at that stage of argument, Marx has already discovered as constituting the commodity. First, the fact that the attribute of general exchangeability is specific to capitalist society (subjective valuation of utility is a human action which occurs in non-capitalist modes of production as well, and yet it does not objectify in the value form of the product). Second, the value form is materially carried by the use value of the commodity as its bearer, which means that the action that posits those two attributes must be the same (in this sense, exchange is an action which *presupposes* rather than posits the existence of the use value of the commodity).

[40] Marx 1976g, p. 128.

[41] This postponement of the naming of value is one of the changes that Marx made to the First Edition of *Capital*. In the latter, the naming of 'value' occurs *before* discovering its content as 'congealed abstract labour' (see Marx 1976e, p. 9). As Fitzsimons (2012, p. 25) notes, the introduction of specific terms *after* the content of their respective determina-

ary literature on Marx's theory of the value form, I think that the (analytic) search for the specific determinations of the commodity – Marx's stated aim in Chapter 1, according to the quote above – is evidently not achieved with the discovery of abstract labour as the substance of value.[42] Quite to the contrary, that very specificity seemed to have slipped through Marx's fingers. In effect, although he found the specific attribute of the commodity in its value, when he moved to account for its substance he ended up with something which bears

---

tions has been unfolded is an aspect of Marx's exposition that recurs throughout *Capital*. This presentational strategy is underpinned by a substantive methodological issue that sets apart dialectics from representational thought. Whereas the latter starts out from 'concepts' or 'categories' (i.e. purely ideal or mental abstractions) and their definitions, in dialectical science definitions do not *determine* in advance the content of a term and therefore cannot be the point of departure of the exposition. Instead, they only encapsulate determinations that have already been laboriously *developed*. In other words, definitions are arrived at rather than departed from.

[42] As a reaction to the ahistorical, Ricardian reading of Marx's account of the value form, the 'new consensus' tends to see abstract labour as a purely historical, specific social form. See, among others, De Angelis 1995; Postone 1996; Reuten 1993; Arthur 2001b; Bellofiore and Finelli 1998; Kay 1999; Saad-Filho 1997; Mohun and Himmelweit 1978; de Vroey 1982; Eldred and Haldon 1981; Bellofiore 2009a; Heinrich 2009; Mavroudeas 2004; McGlone and Kliman 2004; Roberts 2004. I have developed a more extended critique of this new consensus in Kicillof and Starosta (2007a and 2007b). Here I can only offer some brief remarks on this issue. As I argue below, abstract labour is a generic material form, a 'productive expenditure of human brains, muscles, nerves, hands etc.' (Marx 1976g, p. 134). What is specific to capitalist society is the role it plays by being determined as the substance of the most abstract form of objectified social mediation, namely, value. Murray (2000) comes very close to recognising this through the distinction between 'physiological' abstract labour and 'practically abstract' labour. A proper discussion of Murray's own solution to what he terms 'Rubin's dilemma' exceeds the scope of this chapter. Here I would only like to note that Murray's merit is to grasp the importance of highlighting the *materiality* of abstract labour while making clear that this does not necessarily lead to an asocial perspective on the value form. In this way, his recent contribution to the debate provides a necessary correction to what I see as a formalist overreaction of much recent theorising on the value form. See also Reuten's reply to Murray (Reuten 2000) and the latter's rejoinder (Murray 2002). Whilst still seeing abstract labour as capital-specific, Robles Báez (2004) offers probably one of most interesting treatments of the *movement of the contradiction* between the generic, physiological materiality of abstract labour and its historically specific *social* determination as the substance of value deriving from the private character of labour in capitalism. See also Carchedi (2009 and 2011a, pp. 60–74) for a similar argument. The debate on the nature of abstract labour has not been settled and has continued in more recent times. See Bonefeld 2010b and 2011a; Carchedi 2011b; Kicillof and Starosta 2011.

no specifically capitalist character: 'merely congealed quantities of homogeneous human labour, i.e. of human labour power expended without regard to the form of its expenditure'.[43] But it is evident that in any form of society, human beings objectified their subjective labour power and that that process of objectification entailed both a concrete or particular character and an abstract or general one. Thus far, then, this stage of the analytic process does *not* show *why* this generic materiality takes the objectified social form of value. It does not even tell us *what* is the historical form of social labour which is determined as value-producing. It *only* tells us *what* is the *material* determination of that which in capitalist society is *socially* represented in the form of value. This is the reason why Marx still carries on with the analytic search for the '*formal determinants* that it contains as a commodity and which stamp it as a commodity'.[44] This leads Marx's dialectical analysis to give closer scrutiny to the labour that produces commodities. As any attentive reader could tell, the analytic process continues and only in the section on the dual character of labour does Marx finally find the historically specific form of social labour that produces commodities and, hence, value.

In effect, Marx observes that the individual commodity he is analysing is only one among many within a totality of different commodities. But the same follows for the particular labours that underlie the varied use values taking the commodity form. In other words, Marx points out that generalised commodity production presupposes the existence of an extended social division of labour and that the latter, as the 'totality of varying deployments of useful labour', is an 'eternal necessity of nature for the sake of mediating the material interchange between man and nature (i.e. human life)'.[45] On the other hand, this analysis also makes clear that the reverse relationship does not hold, that is, the division of labour must not necessarily take the social form of the production of commodities. The formal determination of the commodity must therefore spring from the specific social form taken by the organisation of the division of labour in our present-day society. The commodity, Marx eventually concludes, is the objectification 'of mutually independent acts of labour, performed in isolation'.[46] In other words, it is the 'labour of private individuals who work independently of each other',[47] or *private and independent labour*, which constitutes the specifically capitalist form of labour or productive activity. In this social form of the human life process, the producer has the full conscious productive capacity to control the individual character of her/his labour, but cannot recognise and organise (i.e. she/he is unconscious about) the social determinations of human individuality. Hence the inversion of those social powers into an attribute of the product of labour, namely, the value form. The analytic process completes the search for the specific determinations of the value form by revealing that the attribute of general exchangeability of the commodity springs from the abstract or general character of socially necessary *privately performed* labour materialised in it. The value form, then, becomes known in its essential determination as the *objectified or reified expression of the social character of the individual labour of private and independent producers*. Its objectivity is thus revealed to be wholly social, without an atom of 'matter' entering into it.[48]

---

[43] Marx 1976g, p. 128.

[44] Note that had abstract labour as such constituted the specificity of value-positing human action, Marx's analytical search would have come to an end.

The Synthetic Phase of Reproduction Proper

It is only now that the synthetic stage of the presentation begins. This consists in ideally following the realisation of the discovered potentiality immanent in the commodity. From then on, the commodity ceases to be grasped in its exteriority as an 'inert' social form – as a sheer external object – and the exposition starts to follow its self-movement as the subject of the development of those determinations – previously discovered through analysis – into its more concrete forms.[49] This is subtly indicated by Marx at the end of his discussion of the qualitative determinations of the relative form of value.

---

[48] Marx 1976g, p. 138.

[49] Iñigo Carrera 2008, p. 321. In a recent article, Arthur (2004a, pp. 41–2) also acknowledges this important aspect of Marx's presentation. However, he still maintains that Marx failed to provide in Chapter 1 an adequate explanation for the determination of abstract labour as the substance of value and should have postponed the introduction of abstract labour until the level of abstraction of the capital form. See also Arthur 2005, p. 119. The shortcoming of this view – also shared by Lapavitsas (2005) and Campbell (2013), the latter following Reichelt (2007) – is that it leads to a formalistic understanding of the value form, which obscures the very question that the latter, in its own reified way, is meant to solve: the establishment of the material unity of social labour when it takes the form of private labour (Brown 2008). This idiosyncratic separation of the form of value from its substance at the level of the commodity form had already been advanced by Itoh (1988). See Clarke (1989), for a critique of Itoh's radical separation of the theory of the form of value and the theory of the substance of value.

> We see, then, that everything our analysis of the value of commodities previously told us is repeated by the linen itself, as soon as it enters into association with another commodity, the coat. Only it reveals its thoughts in a language with which it alone is familiar, the language of commodities. In order to tell us that labour creates its own value in its abstract quality of being human labour, it says that the coat, in so far as it counts as its equal, i.e. is value, consists of the same labour as it does itself. In order to inform us that its sublime objectivity as value differs from its stiff and starchy existence as a body, it says that value has the appearance of a coat, and consequently that in so far as the linen itself is an object of value [*Wertding*], it and the coat are as like as two peas.[50]

The unfolding of this movement spoken 'in the language of commodities' is precisely what the subsequent synthetic stage of the presentation consists of. Being a *purely social* power of the commodity, value cannot be immediately expressed in its sensuous corporeal materiality. As the capacity of the commodity to be exchanged for other different commodities, value can only be manifested in the social relation between commodities. Therefore, the value of a commodity necessarily expresses itself only in the use value of the commodity that is exchanged for the commodity in question as its equivalent. In this way, value takes the concrete shape of exchange value as its necessary form of appearance. In its most developed form, value acquires independent existence as money and the expression of value in the particular commodity acting as money becomes determined as price. The opposition inherent in the commodity is thus externalised through the doubling of the commodity form into ordinary commodities and money. The power of direct exchangeability of commodities negates itself as such to become affirmed as a social power monopolised by the money form.

It is in the course of the synthetic movement of this development, when seen from the point of view of its *qualitative content*, that the answer to the 'why' questions which the analytic stage was unable to provide is given. In other words, it is the development of the expression of value that unfolds the explanation as to why the objectification of the abstract character of privately performed labour takes the social form of value or, to put it differently, why private labour is value-producing.

In a nutshell, the issue comes down to the fact that it is only the expression of value that progressively reveals to us the problem that the commodity form of the product of labour is meant to solve. I am referring to the mediation in the establishment of the unity of social labour when performed in a private and independent manner. And since this unity becomes condensed in the money form, it is the unfolding of its determinations, synthesised in the peculiarities of the equivalent form and derived from its general determination as the form of immediate exchangeability, that provides the answer to the question as to why private labour must produce value.[51]

---

[50] Marx 1976g, pp. 143–4.

As the other side of its two-step analytic discovery, the synthetic ideal reproduction of the determinations of the value form comprises two aspects, each one corresponding, respectively, to the second and third peculiarities of the equivalent form. The first one – whereby the concrete labour that produces the particular commodity acting as general equivalent becomes the form of manifestation of the general character of human labour – shows, precisely, why that material expenditure of labour power has to act as the social form of labour, i.e. why it is that *abstract* labour is the substance of value. The second one – whereby the private labour that produces the equivalent commodity becomes the immediate incarnation of directly social labour – in turn makes it evident why private labour must produce value at all.

---

[51] In the Second Edition of *Capital* and the 'Value form' appendix to the First Edition, Marx develops all the peculiarities of the equivalent form as part of his discussion of the *simple* form of value. By contrast, in the First Edition, the second and third peculiarities are developed in the context of the 'reversed' form of the expanded form of value, an intermediate step which Marx did not include in the Second Edition, where he directly jumped from the expanded form of value to the general form. I think that, for my purpose here, the presentation of the First Edition is clearer. In effect, as Marx himself notes (Marx 1976e, p. 26), the solution to the problem at stake (the establishment of the unity of social labour) is revealed only when the expression of value acquires its plenitude as the form of general exchangeability by relating through the value form the universe of all existing commodities. This only occurs with the general form of value (although a defective – because it is not unified – manifestation, is already found in the expanded form). That is why I shall follow the presentation of the First Edition. On the other hand, there might be a strong reason why Marx decided to move the peculiarities of the equivalent form to the simple expression of value. In a nutshell, the point is that for the presentation of the unfolding of the specific content of the *qualitative* determination involved in the expression of value, its simple form suffices. That is why Marx states that 'the whole mystery of the form of value lies hidden in this simple form' (Marx 1976g, p. 139). The *further* formal unfolding of the more developed expressions of value only entails *quantitative* differences within that very same *qualitative determination* (Iñigo Carrera 2013). Certainly, that purely *formal* construction *helps* the comprehension of the qualitative determination entailed in the form of value by making explicit aspects of the former which are not *immediately visible* in the simple form. But no novel *quality* is unfolded. In this sense, and contrary to the claims of some scholars (Robles Báez 1997), the expansion and inversion of the simple form of value does not entail, properly speaking, any 'dialectical' or immanent self-movement. It is only a wholly formal (hence extrinsic) *representation*, which involves a *quantitative generalisation* of the qualitative determination already *fully realised* in the simple form. Incidentally, this illustrates what is the role of *formal logic* within dialectical knowledge, namely, the *representation* of the (necessarily external) determinations of quantity, that is, of 'difference determined as indifference' (Iñigo Carrera 2008, pp. 269–70). In the words of Hegel, 'a being that is indifferent with regard to determinacy' (Hegel 1991, p. 157).

In effect, through the general expression of value, all commodities relate to each other as possessing an identical social essence as exchangeable things in the same magnitude. In other words, albeit in a mediated form that reflects their social form of value as the immediate attribute of the general equivalent, their social relation of general exchangeability achieves its unity. But since they are only values as expressions of the same common social substance, i.e. abstract labour, the unity of the expression of value puts us before the unity of *undifferentiated* human labour. In determining the concrete labour that produced the equivalent as the immediate mode of appearance of abstract human labour, now the social relation between commodities itself makes plain that the different concrete labours that produced them are but different ways in which the total labour power of society has been expended. Those varied useful labours now show themselves to be what they actually are: differentiations of the expenditure of human labour power or determinate modes in which the human body has been productively exerted. In this 'roundabout way', as Marx puts it, the development of exchange value confronts us with the generic problem that any society must confront, namely, *the social regulation of the differentiation of human labour*, which 'is capable of receiving each and every determination … but is undetermined just in and for itself',[52] and which is necessary for the reproduction of human life. The exposition of the dialectical analysis of the commodity had already discovered that a commodity-producing society presupposed an extended division of labour. Now we can see that the materialised social relation itself – the value form – *affirms itself as the mediator* in the articulation of that division of labour, i.e. in establishing the relation between different labours as organic specifications of human labour in general.

> As *values* the commodities *are* expressions of the *same unity*, of abstract human labour. In the form of *exchange value* they *appear* to one another

---

[52] Marx 1976e, p. 20.

> *as values and relate* themselves to one another *as values*. They thereby relate themselves at the same time to abstract labour as their *common social substance*. Their *social relationship* consists exclusively in counting with respect to one another as expressions of this social substance of theirs which differs only quantitatively, but which is qualitatively equal and hence replaceable and interchangeable with one another … It is only the kind of thing that can turn mere objects of use into *commodities* and hence into a *social* rapport. But this is just what *value* is. The *form* in which the commodities *count* to one another as values – as coagulations of human labour – is consequently their *social form*.[53]

The necessity of abstract labour as the substance of value thus becomes finally unfolded. Abstract labour is the substance of value not because a logical argument says that it is the common property of commodities we were searching for in the name of sound principles of logic. Abstract labour becomes determined as the substance of value because *in reality* the latter is the objectified social form that mediates the organisation of that purely material expenditure of the human body into its different concrete forms across society. Given that the latter is what the value form mediates, what else could be represented in that objectified form? On the other hand, it is self-evident that abstract labour does not cease to be a generic material form because of this determination as the substance of value. Hence, as stated above, the determination of labour as abstract labour is not the reason behind its existence as value-producing labour. What is specific to capitalist society is that this purely material form negates itself as simply such so as to become affirmed as the producer of the (objectified) general social relation.[54] Once objectified, the generic *materiality* of the abstract character of labour plays a particular social role in the process of social metabolism by being represented as the *social objectivity of value*.

> The commodities' social form is their relationship to one another as *equal labour*; hence – since the equality of *toto coelo* [utterly] different labours can only consist in an *abstraction from their inequality* – their relationship to one another as *human labour* in general: expenditures of human labour power, which is what all human labours – whatever their content or mode of operation – actually *are*. In each social form of labour, the labours of

---

[54] Kicillof and Starosta 2007a, 2007b and 2011; Iñigo Carrera 2008, pp. 340–1.

> different individuals are related to one another as human labours too, but in this case this *relating itself* counts as the *specifically social form* of the labours.[55]

To recapitulate, thus far I have discussed how the formal development of exchange value, and in particular the unfolding of the determinations of the second peculiarity of the equivalent-form, contains the account of the reason why *abstract labour* is the substance of value. What still remains to be answered is why this general material character of the expenditure of human labour power becomes *substance of value*. In other words, we have to see why human productive activity becomes determined in capitalist society as value-producing, the second step in the synthetic movement referred to above.

The answer to this question follows from the third peculiarity of the equivalent form. In effect, as the social incarnation of human labour in general, the concrete labour that produces the equivalent acquires in its immediacy the form of equality with respect to the other concrete useful labours. In this form of immediate identity with every other concrete labour, the labour that materialises in the general equivalent is *immediately social*, whilst the useful labours producing the rest of commodities remain *not-immediately social*. Thus the development of the expression of value in the form of exchange value puts us before the reason why the organisation of the division of labour must necessarily be mediated in this reified form or, what is the same, why commodity-producing labour is essentially value-producing. Although materially dependent upon one another as part of the 'primordial system of the division of labour', this irreducibly social character of *private labours* is not immediately manifested when they are actually objectified in the direct process of production. Hence, this necessary social articulation of private labours is realised through the mediation of the exchange of the products of private labour as commodities. Only at that moment is the question of whether the expenditure of the portion of social labour which each producer personifies is socially useful able to be answered. This is the reason why the social character of the privately performed individual productive activities is specifically represented as a determinate objective attribute of the products of labour: the form of their general exchangeability or their value form. The basis of this reified social mediation thus resides in the fact that the unity of social labour is manifested, as Marx puts it in the *Grundrisse*, only *post festum*, through the exchange of the products of labour.[56] Furthermore, the unity of social labour thus becomes socially represented in the form of the particular private product that the rest of commodities separate as their general equivalent and which eventually ossifies in the money form. In tracing the genesis of the latter through the ideal reproduction of the expression of value, the synthetic stage of the dialectical exposition thereby positively unfolds the determinations of that which the analytic process could only *point out*. Namely, that the value form of the product of labour is the materialised general social relation of human beings in the capitalist mode of production and, therefore, the *social subject* of the *form* taken by the social process of production of human life in this historical stage of its development.[57]

---

[55] Marx 1976e, p. 32.

Only at this juncture does Marx introduce the fundamental discussion of the fetish character of commodities. The question that immediately arises, and which is hardly addressed in the literature, is why only and precisely then? I think that the answer to this question is inseparable from the issue about the determinate content of the section on commodity fetishism and its place in the overall structure of Marx's exposition in *Capital*. The aim of the next chapter, then, is to proceed to deal with these questions. Again, I will show that only through a proper grasp of the dialectical method can the full implications and significance of Marx's account of commodity fetishism be uncovered.

---

[56] Marx 1993, p. 172.

[57] We shall see that in becoming capital, the materialised social relation of private and independent individuals is constituted as the social subject of the form *and content* of the process of production of human life.

Which 'Rational Kernel'? Which 'Mystical Shell'? A Contribution to the Debate on the Connection between Hegel's *Logic* and Marx's *Capital*

Gastón Caligaris and Guido Starosta

1 The Issue at Stake

The question about Hegel's legacy in the Marxian critique of political economy has been one of the most widely debated issues within the history of Marxist thought. In recent decades, a new strand of scholarly work has emerged which has radically challenged the 'received wisdom' about the 'Hegel–Marx connection'.[1] Usually grouped under the 'systematic dialectic' label, this novel assessment of the intellectual relationship between the two German thinkers has decisively broken with the orthodox views of Diamat as epitomised in Stalin[2] and official Soviet manuals, which in turn drew direct inspiration from the classical works of Engels,[3] Plekhanov[4] and Lenin.[5] On the other hand, this new critique has also provided an alternative to the views associated with the so-called 'Western Marxist' tradition, whose interest in the recovery of the Hegelian lineage in Marx's thought fundamentally centred on reinstating the rôle of subjectivity against the crude objectivism and economism of Diamat.

This more recent strand of research has focused on the *methodological* relevance of Hegel's thought for the development of the Marxian critique of political economy. More specifically, whereas in earlier studies the emphasis was mainly on the relationship between Hegel's *Phenomenology of Spirit* and the 'young Marx', this more recent literature has focused on the links between *Capital* and Hegel's *Science of Logic*. Although there are various particular controversies over the precise nature of this connection, most contributions agree that the structure of the argument in *Capital* is organised in a dialectical form which, at the very least, can be said to draw formal inspiration from the general form of movement of categories that Hegel deploys in his *Logic*. Thus Marx's presentation is seen as involving a (synthetic) movement from the more abstract or simple form-determinations of the subject-matter (namely, capital) to the increasingly more concrete or complex forms in which it moves and eventually manifests in 'empirical' reality, thereby culminating in the intellectual reproduction of capital as the unity of those many determinations. Inasmuch as the transition from one economic form to the next is seen as being driven by the development of the contradictions immanent in each of them, their relationship is generally deemed as internal and grounded in dialectical necessity, in contrast with the externality that inevitably results from the use of formal logic.

[5] Lenin 1977 [1908], and 1976 [1895–1916].

Now, beyond this general consensus within the 'systematic dialectic' literature, two broadly defined approaches can be identified.[6] Firstly, there is the group of authors who examine the Hegel–Marx connection through the so-called 'homology-thesis'. Perhaps the most emblematic contribution from this perspective can be found in the work of Chris Arthur,[7] who argues for the existence of a very close '*homology* between the structure of Hegel's *Logic* and Marx's *Capital*'.[8] According to this approach, a strict mapping of most categories of the *Science of Logic* onto the systematic presentation in *Capital* is possible (and actually illuminating), 'because capital is a very peculiar object, grounded in a process of real abstraction in exchange in much the same way as Hegel's dissolution and reconstruction of reality is predicated on the abstractive power of thought'.[9]

The second strand within the 'systematic dialectic' literature consists in a materialist reading of Hegel's work in general and the *Logic* in particular. Tony Smith's work is perhaps the most representative of this perspective.[10] The essential point made by Smith is that Hegel's dialectical method *fully* coincides with Marx's, notwithstanding the latter's repeated remarks to the contrary throughout his lifetime. The *Logic* is thus read as a systematic-dialectical exposition of the fundamental ontological structures of real material being, that is, as a 'materialist ontology'.[11] The relevance of the *Logic* thus derives from providing the basic categories that are needed to capture the 'intelligibility' of the material world.[12]

In sum, whereas for Arthur's approach the content of the *Logic* is *purely and absolutely idealist*, according to Smith's interpretation it is *sheer materialism*.

[12] Smith 1990, p. 5.

Whereas for Arthur's homology-thesis the *Logic* can shed light on capitalist social forms only, for Smith's Hegel-as-materialist reading its field of 'applicability' or relevance is broader and could in principle include non-capitalist social forms and natural forms as well. Finally, whereas according to Arthur the Marxian critique of political economy can benefit from the discovery of homologous logical forms implicit in the inner connection between the different form-determinations of capital, for Smith the question is rather that of becoming aware of the general ontological structures that organise the systematic ordering of economic categories.

Now, this debate about the significance of the *Logic* for the critique of political economy can be reframed in terms of Marx's well-known explicit statement about the relationship between his dialectical method and Hegel's: the key issue at stake seems to be the establishment of the precise nature of the rational kernel within the (allegedly) mystical shell.[13] This chapter attempts to contribute to the debate by providing an alternative perspective on the connection between Hegel's *Logic* and Marx's *Capital* to the two just sketched out above. Drawing on Juan Iñigo Carrera's work on the relationship between the dialectical method and the critique of political economy,[14] we shall argue that the methodological and scientific significance of the *Logic* – the 'rational kernel' – does not come down to offering the purely logical form of capital's peculiar inverted ontology. Here we tend broadly to concur with Smith's critique of the homology-thesis. However, *contra* Smith, we shall also show that the content of the *Logic* cannot be simply taken over for a Marxian 'systematic dialectic'. As we shall see, the 'mystical shell' affects the very structure of Hegel's book.

2 Marxists on *Science of Logic*'s Rational Kernel and Mystical Shell

In the founding works of Diamat, the *Logic* is usually taken as containing 'the fundamental laws of dialectics', which are then to be applied to more concrete objects such as history, capitalism, and so on. It is thus argued that Hegel would have discovered those laws but 'in his idealist fashion as mere laws of thought'.[15] In so far as those texts do not offer any substantive critique of the specific content developed in the *Logic* (which in many cases they simply reproduce almost word by word), it must be assumed that for this reading the rational kernel consists in the dialectical unfolding of the logical categories just as is presented by Hegel. For its part, the mystical shell is seen in Hegel's claim that the subject of those different logical forms is not the real human being 'reflecting' in his brain the structure and movement of matter or nature, but the 'Absolute Idea'. This position is nicely expressed by Lenin's famous aphorism: the question is how to 'read Hegel materialistically ... that is to say ... cast aside for the most part God, the Absolute, the Pure Idea, etc.'[16] It would seem, then, that the matter comes down to the substitution of a materialist terminology for Hegel's idealist one, that is, replacing the term 'Idea' with the word 'matter'.

---

[14] Iñigo Carrera 1992, 2007, 2013, and in this volume.

[15] Engels 1987b [1872–82], p. 356.

This orthodox interpretation has been challenged from two opposing perspectives. The first one submits that uncritically appropriating the systematic-dialectical method unfolded in the *Logic* necessarily involves accepting Hegel's absolute idealism. In this sense, there simply is no rational kernel to discover. At the other end, some authors argue that the *Logic* does not deal with any metaphysical super-subject, but only unfolds systematically all the necessary categories for making intelligible the more abstract ontological structures of the material world. As a consequence, this reading tends to conclude that there actually is no mystical shell. Hegel's *Logic* is therefore seen as all rational kernel from beginning to end.

Lucio Colletti's influential *Marxism and Hegel* is a good illustration of the first perspective.[17] According to this author's provocative thesis, the main achievement of Hegel's *Logic* is to offer, for the first time in the history of philosophy, a solid exposition and justification of 'idealism in a logically coherent fashion'.[18] And it does this precisely by resorting to the dialectical method. Colletti makes his case by critically examining the dialectic of the finite and the infinite that Hegel develops in the 'Logic of Being'. In this reading, the demonstration of the contradictory character of the finite contained in those pages constitutes a key moment in Hegel's speculative philosophy, since 'finitude is the most stubborn category of the understanding'.[19] The reason for this speculative significance is that in the finite the understanding grasps 'the negation as *fixed in itself*, and it therefore stands in abrupt contrast to its affirmative',[20] that is, the infinite. In sticking to the fixity of finite being, that is, in denying the dissolution of the finite or the 'ceasing to be of the ceasing-to-be',[21] the understanding can only grasp it 'as irreconcilable with the infinite'[22] and, hence, condemns the mediation between them to failure. On the contrary, with the awareness of the contradictory character of the finite and its resulting 'ontological instability', Hegel is able to reveal how the finite, through its own immanent dialectic, passes over into the infinite. In this way, he overcomes the radical opposition between them, a task which the understanding is unable to achieve. However, Colletti's argument goes on, Hegel can only succeed at this by condemning the finite to unreality or ideality. In other words, Hegel can provide a rationally coherent speculative mediation of the finite and the infinite by reducing the former to a vanishing moment of the latter's process, which alone possesses 'true' reality. On the other hand, Colletti points out that for Hegel only thought has universality and infinity. The dialectic of the finite is thus equated by Hegel to the 'annihilation of matter'. Thus Colletti concludes that this demonstration of the dialectical or self-contradictory character of finite being must of necessity entail absolute idealism, since the sensuous material world (the finite) is conceived as a mode of existence of thought (the infinite). The dialectical method, that is, the conception according to which 'everything finite is alterable and perishable' and 'being implicitly the other of itself, is driven beyond what it immediately is and overturns into its opposite',[23] is for Colletti inherently idealistic.[24]

[20] Hegel 1999 [1812–16], p. 130.

[21] Hegel 1999 [1812–16], pp. 130–1.

Now, if we examine more closely the dialectic of the finite in *Science of Logic*, it becomes clear that, *pace* Colletti, those pages do not develop a demonstration of the ideal character of the sensuous material world and therefore do not provide the key argument for the idealist nature of Hegel's system.[25] The only thing that Hegel is proving there is the fact that things are 'finite' means that they carry within themselves the necessity of their own negation. Consequently, they cannot be properly grasped if represented as self-subsistent entities or immediate (or unmediated) affirmations. Instead, things or objects need to be grasped as *self-moving*, that is, as *subjects* of their own qualitative transformation into another 'finite' form. An object thus realises its own qualitative determination by becoming another, that is, through *self-mediation*. This is, in our view, all that Hegel is trying to expound in those pages: real forms of 'being' affirm through self-negation. It is in that specific sense that according to him reality is the *movement of contradiction*. To put it differently, Hegel's point in those pages is just to say that the true infinite is nothing but the immanent *self*-movement of the finite, which it affirms through self-negation. Colletti's reading of those texts, which conflates Hegel's *systematic exposition* and his indisputably idealist remarks in the *addendum*, leads him to throw the baby out with the bath-water.

[25] See Houlgate 2005, p. 429.

Thus, Hegel's insight into the self-moving nature of real forms, which constitutes his great scientific discovery and thus the rational kernel to be found in the *Logic*, is not inherently tied to his absolute idealism. In fact, following Iñigo Carrera,[26] one could argue that the opposite is the case. In other words, it is the rejection of that Hegelian discovery that inevitably leads to an idealist representation of reality. In effect, when real forms are represented as devoid of any immanent necessity driving them to self-movement, forms of 'being' are reduced to lifeless abstractions which can only be put into *external* relation with each other by means of subjective reflection. An unbridgeable gap between knowledge and reality is bound to emerge. As a consequence, the relations between objects that are then established through the act of cognition (that is, the theoretical construct) must inevitably remain alien to the immanent nature of things themselves. In this way, although ideas are not believed to 'produce' reality by this train of thought, it follows that they do bestow movement upon real forms (thereby determining the nature of their mutual relations). Conversely, only when things are grasped as bearers of an intrinsic objective potentiality for self-movement does it make sense to raise the question of the ideal reproduction of the 'immanent life' of the subject-matter.

This last point can perhaps serve us to bring out more clearly the difference between Colletti's ultimately Kantian perspective and Marx's materialist-dialectical method. Colletti, in a truly Kantian fashion, saw more abstract determinations of objects as merely subjective ideas that help organise a given, immediately-perceived content, of which alone he is ready to predicate materiality and sensuousness.[27] By contrast, Marx considered the non-immediately perceptible, more abstract determinations of real forms as *objective*, even if cognised only by means of thought. On this particular point, Marx was fundamentally in agreement with Hegel although, as we shall see in the next section, he did consider that such rational insight was presented in the *Logic* within a mystical shell.

Let us now turn to the other position on the rational kernel and mystical shell in Hegel's *Logic*, which can be found in the aforementioned work of Tony Smith. According to the argument put forward in his book *The Logic of Marx's*

---

[26] Iñigo Carrera 2013.

[27] Strictly speaking, Colletti does recognise the objectivity of abstract forms, but only for capitalism, whose 'social ontology' gives rise to a suprasensible 'world of abstractions' (Colletti 1973 [1969], p. 227ff). Here he anticipates some of Arthur's ideas.

'Capital', Hegel's *Logic* deals with the fundamental categories of thought that are necessary to grasp the inner intelligibility of reality. In this treatment of logical categories, Smith argues, Hegel 'derive[s] three general types of categorial structures', one of 'simple unity', another of 'difference' and, finally, another of 'unity in difference'.[28] Moreover, in so far as those categorial structures are immanently and contradictorily connected, it is possible to 'construct a systematic theory of categories by employing the dialectical method'.[29]

In this reading, the *Logic* turns out to be entirely 'compatible with Marx's materialist ontology',[30] so that there is no reason to reject it for its idealism. Moreover, the alleged ground of Hegel's idealism cannot even be found where Marx himself thought it could be located, that is, towards the end of the categorial construction, at the point where Hegel unfolds the transition to the realm of nature and of human spirit as the self-negating action of the Absolute Idea. According to Smith, in those passages Hegel 'is indulging in picture-thinking, in imaginative representations that on his own terms belong on a pre-philosophical level',[31] a form of expression that he was compelled to resort to in order to make his philosophy appealing to a mainly Christian readership.

Now, if we set aside the thorny question of textual support for this reading, Smith's interpretation would indeed be plausible and, if correct, would certainly free Hegel's philosophy from charges of absolute idealism. However, this would not automatically turn Hegel into a materialist in Marx's specific sense. In order to prove this, a different kind of argument would be needed. Above all, proof should be provided that the structure of real material being actually coincides with the structure of pure thought-forms presented in the *Logic*. Smith's further claim that the categories presented in that work 'are initially won in confrontation with the empirically given'[32] will not do either, since that is far from guaranteeing that the *systematic ordering* of those categories ideally reproduces the 'immanent life' of real material being. To put it differently, the question about the alleged materialist character of the *Logic* cannot be settled with evidence of Hegel's recognition of an objective reality existing outside thought. Instead, we think that the crux of the matter is whether the Hegelian systematic dialectic of logical forms correctly reproduces the more abstract determinations of material reality 'by means of thought'.

---

[28] Smith 1990, pp. 5–6.

[31] Smith 1990, p. 11.

[32] Smith 1990, p. 4.

As we intend to show in the next section, Hegel's systematic development in the *Logic* is inherently flawed as an ideal reproduction of the inner connection between the more abstract forms of material reality. In a nutshell, we argue that in so far as his systematic dialectic begins with the simplest *thought-form* (*that is, with a purely ideal or formal abstraction*), his subsequent derivation of categories is bound to follow the immanent necessity of 'pure thought' as such, which, we shall further submit, does not express the inner movement of the simpler determinations of 'real material being'. In this sense, we do think that the peculiar form given by Hegel to his systematic dialectic is immanently bound to an idealist standpoint, although for very different reasons from those put forward by Colletti. This does not mean that there is nothing to recover from Hegel's immanent development of thought-forms. It only means that those rational elements need to be carefully discovered within a presentation which is, by virtue of its idealist nature, structured in such a form and ridden with categories that would have no place in a materialist systematic dialectic. Seen in this light, the main problem with Smith's perspective is not that his materialist reading of Hegel is not convincing. Rather, the key issue is that he takes over from Hegel a systematic dialectic which is quite simply flawed. As a consequence, alongside the 'rational kernel', he cannot but carry over the 'mystical shell'.

3 The Rational Kernel and Mystical Shell in Hegel's *Logic*

Abstraction versus Analysis

The starting point of the *Logic* is 'pure being' as thoroughly 'empty thinking'.[33] In other words, the book begins with being as a *thought-form* or the *thought of being*. The profound meaning and broader significance of this peculiar point of departure in Hegel's philosophy has been the subject of numerous controversies among commentators, particularly with regard to the connection between this category of thought and 'real being'. However, few scholars have actually taken Hegel to task for beginning his systematic dialectic with a thought-form. We shall consider below the implications that this point of departure has for the main theme of this chapter, namely, the rational kernel and mystical shell to be found in the *Logic*. For the moment, let us first critically examine the methodological procedure that is presupposed by Hegel's discovery of 'pure being' as the simplest category that sets into motion the subsequent dialectical unfolding of logical forms.

---

[33] Hegel 1999 [1812–16], p. 82.

Hegel's choice of categorial starting point and the procedure by which he arrives at it follows from his idea that true speculative philosophy must involve *presuppositionless thinking*.[34] The 'beginning', he states, 'must be an *absolute*, or what is synonymous here, an *abstract* beginning; and so it *may not presuppose anything*'.[35] 'Strictly speaking', he further argues in the *Encyclopaedia*, 'this requirement is fulfilled by the freedom that abstracts from everything, and grasps its pure abstraction, the simplicity of thinking'.[36] More concretely, the procedure through which one can arrive at this pure abstraction consists in casting aside any thought that entails a certain complexity or concreteness, that is, any thought whose content presupposes the existence of any other thought. At this juncture, one could of course object that such an elementary abstraction would not have been reached on properly scientific grounds, that is, that it would be the result of a purely formal procedure that does not guarantee that we have actually reflected the immanent life of the subject-matter under consideration. In other words, this category would be a purely *formal abstraction* resulting from an act of subjective reflection that remains external to the object of cognition. Indeed, Hegel's retrospective discussion of the beginning of science in the section on the Absolute Idea speaks to this issue: the simplest category constituting the point of departure of his *Logic* is depicted as an 'abstract universal', which is said to be arrived at by *abstracting from* all determinacy.[37] In other words, pure being, as the category that sets into motion the (synthetic) movement of the *Logic*, is a category akin to those of the 'understanding' or 'representational thought', that is, one which only grasps objects one-sidedly in terms of their abstract self-identity.[38] In fact, as Carlson suggests, it could be said that it is actually the understanding that undertakes the act of abstraction and not speculative thought as such.[39] In this sense, Hegel saw the specificity of his 'absolute method' as essentially residing in the synthetic moment, that is, in the reconstitution of the unity of the different moments of the totality through a movement from its most abstract thought-form (pure Being) to its most concrete (the Absolute Idea).[40] Thus, he did not seem to recognise anything specifically speculative in the procedure through which the simplest category is arrived at, that is, in the reverse movement from the concrete to the abstract which the synthetic phase of systematic science presupposes.

---

[34] Houlgate 2005, p. 29ff.

[35] Hegel 1999 [1812–16], p. 70.

[36] Hegel 1991 [1817], p. 124.

[37] Hegel 1999 [1812–16], pp. 69–72, 827–9.

[38] Hegel 1999 [1812–16], pp. 795ff, 828.

[39] Carlson 2007, pp. 27–8.

[40] Hegel 1999 [1812–16], pp. 830–1, 838.

Still, for Hegel such a discussion of the nature of the act of abstracting is immaterial at the initial stage of the investigation, since, strictly speaking, science proper has not actually begun. As he puts it some pages later in the *Logic*, '[w]hen being is taken in this simplicity and immediacy, the recollection that it is the result of complete abstraction ... is left behind, outside the science'.[41] As a contemporary Hegel scholar nicely puts it, in order to remain firmly on the path to a science without presuppositions, 'we must even abstract from and set aside – indeed deliberately forget – the very fact that pure being is the product of abstraction'.[42] Indeed, *once the standpoint of 'absolute knowing' is adopted*, and therefore *thought* as such is taken to be the legitimate immediate object of the investigation, the scientifically poor nature of the procedure through which its simplest category has been grasped (that is, the relative poverty of formal abstraction) does not compromise the validity of the subsequent dialectical unfolding that 'pure Being' sets into motion. Thus, regardless of the procedure used, the essential point is that in this process the speculative thinker has never abandoned his/her 'object-realm', namely, pure thought. In this sense, as long as (some version of) the identity of thought and being reached in the *Phenomenology of Spirit* is taken on board, Hegel's argument is perfectly coherent on this score, although, as we argue below, it is still inherently tied to his idealism.

However, matters are very different from a materialist standpoint. From this perspective, the method of formal abstraction as the prelude to synthetic development is rather problematic. In effect, when the immediate object of the act of cognition is not thought of as an existing form of 'material being', the formal abstraction resulting from arbitrarily casting aside all specific determinations inevitably takes us rather far from, and actually outside, the very 'object-realm' that we originally set about to cognise, namely, material reality. Following Marx's example in *The Poverty of Philosophy*,[43] if we abstract from the materials which make up a house, the result will be a purely ideal representation of a house with no materials, something which has no real referent, since there is no such thing in material reality. Hence, in abstracting from particular features of a concrete material object (a procedure that can be repeated as many times as the thinker wishes in order to find an ever simpler or more universal determination), we will no longer be dealing with really existing objects but with purely ideal or mental abstractions, that is, with 'pure thoughts'. On this basis, the subsequent reconstitution of the unity of the object cannot but result in a purely ideal construct, which will remain external to the object of cognition that constituted the starting point, and which only by chance will reproduce in thought 'the immanent life of the subject matter'. It follows from this that for a materialist, the consequence of using the method of formal abstraction is, if he/she does not wish to become a Hegelian idealist, the relapse into Kantian dualism, where the theoretical construct, no matter how internally consistent or coherent, will inevitably be radically separated from the real object of cognition.

[43] Marx 1976b [1847], p. 163.

This is why we think that a materialist engagement with Hegel's *Logic* cannot avoid the critique of the initial formal abstraction that sets into motion the whole systematic development. This is precisely the cornerstone of Feuerbach's foundational critique of Hegel, as the following passage from *Principles of the Philosophy of the Future* eloquently puts it. Hegelian philosophy, Feuerbach states:

> presupposes nothing; this is nothing more than to say that it abstracts from all objects given immediately . . . In short, it abstracts from everything from which it is possible to abstract without stopping to think [*sic*], and makes this act of abstraction from all objectivity the beginning of itself.[44]

A few years later, Marx would develop in *The Poverty of Philosophy* a critique of Hegel's idealist abstraction along clearly Feuerbachian lines.

> Is it surprising that everything, in the final abstraction – for we have here an abstraction, and not an analysis – presents itself as a logical category? . . . If we abstract thus from every subject all the alleged accidents, animate or inanimate, men or things, we are right in saying that in the final abstraction, the only substance left is the logical category. Thus the metaphysicians who, in making these abstractions, think they are making analyses . . . are right in saying that things here below are embroideries of which the logical categories constitute the canvas.[45]

The significance of the latter passage for the purpose of our argument is that it brings to light Marx's alternative to Hegel's procedure of formal abstraction, namely *analysis*. Unfortunately, despite the stark contrast between abstraction and analysis made in the text above, and the many occasions on which Marx highlights the important rôle of analysis as a necessary moment of his scientific method,[46] there is no place in his works where he fleshes out in any detail the specific form of the analytical process within his materialist 'systematic-dialectical' approach. Moreover, despite all the light that the recent works on Marx's method have cast on the form of his systematic argument, they have been mainly focused on the *synthetic* aspects of Marx's dialectical presentation (that is, on the exposition of the dialectical movement 'from the abstract to the concrete'), at the expense of an insufficient thematisation of the peculiar rôle of the phase of analysis in his dialectical investigation generally, and in his presentation in *Capital* in particular.[47] And yet, we would like to argue that it is of utmost importance to grasp the difference between materialist analysis and Hegel's idealist abstraction. True, many authors have highlighted the distinction between the abstractions of Marx's critique of political economy and those of conventional social science.[48] However, not so many have critically engaged with Hegel's abstracting procedure. More importantly, as Iñigo Carrera points out, most authors have overlooked that the difference in the respective kinds of abstraction emerges as a result of the very *form* of the process of cognition on the basis of which those abstractions are identified.[49] This difference in form not only applies to the synthetic or genetic phase as is usually assumed, but crucially pertains to the process of analysis as well.

---

[44] Feuerbach 1986 [1843], p. 19.

[45] Marx 1976b [1847], p. 163.

Although Marx did not leave us any written formalisation of the specificity of materialist analysis, it is possible to grasp its concrete workings from the 'analysis of the commodity' contained in the opening pages of *Capital*.[50] As he explicitly states in the 'Marginal Notes on Adolph Wagner's *Lehrbuch der politischer Oekonomie*', this analysis takes as a point of departure neither the concepts of political economy nor any concept whatsoever.[51] Instead, he starts with the immediate observation of 'the simplest social form in which the labour-product is presented in contemporary society':[52] the *commodity in the form in which it appears*. From this starting point, Marx proceeds by taking the individual commodity 'in his own hand' and analysing 'the formal determinants that it contains as a commodity and which stamp it as a commodity'.[53]

---

[46] Marx 1973 [1857–8], p. 100, and 1989, p. 500.

[47] An outstanding exception can be found in the work of Iñigo Carrera (1992, 2007, 2013, and in this volume), on whose contribution we fundamentally draw.

[48] See Gunn 1992, p. 17, Clarke 1991, p. 81ff, and Murray 1988, p. 121ff.

[49] Iñigo Carrera 2013, p. 50ff.

[50] Since it is in the synthetic phase only that the unfolding of the real movement or life of the subject-matter and hence the explanation actually takes place, the presentation of the findings of the dialectical inquiry could take, in principle, a fully synthetic form (Iñigo Carrera 1992, p. 41). However, this is not the way Marx structured his dialectical exposition in Volume I of *Capital* in general and in Chapter I in particular; this exposition tends to include, in a 'stylised' form, brief presentations of the analytic process (Iñigo Carrera 1992, p. 46). In a context where Marx was presenting his materialist-dialectical method for the first time, his decision to include the analytical phase in the exposition might have played the rôle of bringing out its specificity *vis-à-vis* Hegel's idealist procedure.

These 'formal determinants' Marx initially discovers by looking at the use-value of the individual commodity, which in capitalist societies acts as bearer of a second, *historically specific* attribute of the products of labour. As happens with every real form, the first thing he encounters when facing the exchangeability of the commodity is its *immediate manifestation* – the quantitative relation 'in which use-values of one kind exchange for use-values of another'.[54] The next step in the analysis of exchangeability is the uncovering of the *more abstract form* (hence the *content*) behind that specific formal attribute of the commodity, this being the only way in which we can penetrate through the concrete form in which an immanent determination presents itself. Thus, the further analysis of the commodity reveals that exchange-value is actually the 'mode of expression' or 'form of manifestation' of a content distinguishable from it – value – the substance of which resides in the abstract labour congealed or materialised in it.

As is now widely acknowledged in the literature, the sequence at that particular stage of Marx's argument consists in going from *form* to *content*. However, the crux of the matter does not simply reside in realising this (which, at any rate, is explicitly announced by Marx himself in those pages), but in grasping the precise way in which properly dialectical analysis discovers the content behind the form and, therefore, their inner connection.

As Iñigo Carrera points out, conventional scientific method analyses a concrete form by separating what repeats itself from what does not in order to arrive at a certain characteristic. In turn, this common attribute makes possible the mental construction of a definition of that concrete form as that which has this or that attribute.[55] On his part, Hegel's pure abstraction in the *Logic* proceeds by casting aside all particular features of objects (that is, all determinacy) in order to find through that one step the 'abstract universal' that constitutes its simplest element. Regardless of their differences, these two procedures have in common that they result in strictly mental abstractions or categories which, by their own nature as 'pure thoughts', cannot but remain external and alien to the forms of material reality. Conversely, dialectical thought analyses a concrete form by, first of all, facing it as embodying a qualitative potentiality for transformation, and second, by grasping that qualitative potentiality as the concrete form in which a more abstract form realises its own qualitative potentiality, that is, its real necessity. Thus the dialectical ideal appropriation of the universe of different real forms does not proceed through an identification of the distinctiveness of forms on the basis of the degree of repetition of certain attributes. But neither does it operate by *abstracting from* every particular determination. Rather, it analytically separates the different forms by discovering as *immanent* in a particular concrete form the realised potentiality of another real form, which is abstract with respect to the first one, but concrete with respect to another form of which it is the realised potentiality.

[55] Iñigo Carrera 2013, pp. 50–1.

While conventional scientific method grasps the general determination of real forms as immediate affirmations and hence self-subsistent entities, the distinctive mark of the process of analysis in dialectical research is to grasp, *in the same analytic movement*, both the concrete form under scrutiny and the more abstract one of which the former is the developed mode of existence. In other words, dialectical thought grasps each form as the affirmation through self-negation of another, more abstract one (hence, as subjects of their own movement). Moreover, in contradistinction to Hegelian abstraction or conventional scientific analysis, Marx's dialectical analysis at no point leaves the terrain of the real. Both the immediate concrete form that he encounters and the relatively more abstract one discovered through analysis (the content) are wholly objective and real determinations of the object under scrutiny. This analytical procedure must be then renewed for those other more abstract forms, but now treated as the real concrete whose inner content the research is trying to uncover. Only once all those inner form-determinations have been discovered through analysis should the investigation undertake the 'return-journey' through which those abstract determinations, now in their self-movement, lead to 'the reproduction of the concrete by means of thought'.[56]

Ideal Reproduction of the Ideal versus Ideal Reproduction of the Concrete

Let us now return to the *thought of being* with which the *Logic* begins. As we have seen, this pure being is the product of total abstraction and, from a materialist standpoint, cannot be a real being; it can only exist as a *thought-form*. However, it could still be argued, as Smith does, that such thought of being is

---

[56] Marx 1973 [1857–8], p. 100.

'isomorphic' with (hence reflects) real material being, so that there would be nothing problematic in unfolding the immanent life of the former as a substitute for the latter. If we took on board Hegel's characterisation of pure being as being that simply is, one could argue that the least that can be thought about any real object is that it is. Thus, according to this view the structure of ideal being would fully coincide with that of real being on this point.[57] However, nothing guarantees that the simplest (or rather poorest or emptiest) statement that we could utter 'to make an object intelligible' actually coincides with the simplest form in which a real concrete exists. In fact, as we suggest later on, the simplest form of existence of 'real material being' is not 'pure being'. In light of the previous section, we would be entitled to claim that the former and the latter coincide only *after* submitting an existing object to materialist analysis in the sense discussed above. In other words, only if after uncovering the respective content of each form-determination that we find *within* the real concrete under scrutiny, we encountered pure being as the simplest of them all, would it be scientifically correct to undertake the synthetic phase of reproduction with that 'category' as starting point. However, we have shown that this is not what Hegel actually did. And neither is it what those materialist readings of Hegel do.[58]

Still, if we further insisted on the isomorphic structure between the respective simplest forms of ideal and material being, the divergence between Hegel's idealist construction and material reality would re-emerge in the second step of the systematic unfolding of categories, namely, the passing over of pure being into pure nothing. If in the case of pure being there is at least the formal possibility that it ideally reflects the simplest determination of material being, in the case of pure nothing even that formal possibility should be ruled out from the outset. Indeed, from a materialist standpoint, the reality of pure nothing is simply meaningless. Thus, as Feuerbach's early critique sharply puts it, 'the opposition itself between being and nothingness exists only in the imagination, for being, of course, exists in reality – or rather it is the real itself – but nothingness, not-being, exists only in imagination and reflection'.[59]

---

[57] Houlgate 2005, pp. 140–2.

[58] Smith's interpretation is a case in point. Despite correctly distinguishing between formal and real abstractions (Smith 1990, p. 60), he approvingly presents Hegel's 'analysis' as involving the 'appropriation of the results of empirical studies' undertaken by 'empirical sciences' (Smith 1990, p. 4); which is certainly different from the ideal appropriation of the real abstract forms of a given concrete object. As a matter of fact, those abstractions borrowed from empirical sciences have been constructed on the basis of the conventional scientific method. As argued above, they cannot but be purely formal or ideal.

[59] Feuerbach 1983 [1839], p. 126.

Having ruled out the material existence of pure being and nothing, one could still search for the alleged correspondence between Hegel's *Logic* and material reality in the third moment of their dialectic, that is, in 'becoming'.[60] Thus considered, being and nothing could be said to be just analytical moments which are necessary to grasp the truly simplest logical category – becoming – which would at last reflect the simplest form of real material objects, being a subject that posits its own movement. If this were the case, one could conclude that, despite conceiving it as a movement of pure thought, Hegel would have managed to grasp the simplest content of real being. However, 'becoming' is for Hegel a category that is still quite far from fully expressing the constitutive contradiction of a self-determining or self-moving subject. In so far as Hegel's *Logic* unfolds the immanent necessity of thought as such, starting from its simplest (or rather emptiest) form, his categorial development needs to go through a long series of still more complex thought-forms before being able to express fully the said movement of contradiction that constitutes the simplest determination of real materiality.

In fact, the actual point at which Hegel's exposition eventually reaches a category that fully expresses the simple movement of a self-determining subject, comes quite a few pages and categories later. Specifically, this point is only reached with the category of 'being-for-self', where Hegel finally states that 'qualitative being finds its consummation' so that, therefore, we have at last arrived at 'absolutely determined being'.[61] However, from a materialist standpoint, this begs the question as to why cognition of the real concrete needs to go over those other imperfect forms of ideally expressing the simplest movement of material qualitative determination, which only grasp the latter in its outward or external manifestations: whether as an immediate affirmation (being) or as the extrinsic unity of two opposed immediate affirmations (determinate being). Indeed, one would be led to conclude that the unfolding of those categories is quite simply superfluous. In effect, from this perspective, the imperfect forms of ideally expressing the 'affirming through self-negation' are not *materially constitutive* of what this movement actually is.

Still, a final argument for a materialist reading of the categories preceding 'being-for-self' could state that their exposition corresponds to the *analytical process* of discovery of the category that is able fully to express the real movement of affirmation through self-negation. The problem with this line of reasoning is that according to Hegel's perspective, those poorer ways of conceiving qualitative being have the same status of objectivity as its fully-developed shape. In this sense, the movement from these poorer forms of expressing qualitative being to its consummation in being-for-self is not seen by Hegel as essentially analytic but *synthetic*. In so far as the *Logic* unfolds the immanent necessity of 'pure thought' as such, the imperfect forms of thinking about this peculiar 'being' are as constitutive of this 'object-realm' as their perfectly developed modes of existence. Thus, it is entirely coherent for Hegel to include those categories in his systematic dialectic of thought-forms. However, the consequence of this is that any attempt to take over Hegel's *Logic* as a whole will take the mystical shell (that is, the whole series of superfluous imperfect categories that pure thought needs to posit before reaching the plenitude of its content) alongside the rational kernel (the category that eventually expresses the determination at stake in an adequate form).

---

[60] Hegel 1999 [1812–16], p. 82.

[61] Hegel 1999 [1812–16], p. 156.

It follows from this that a reading of the *Logic* from a materialist perspective cannot consist in just 'casting aside God, the Absolute, the Pure Idea, etc.' or in uncovering the logical structure articulating the systematic ordering of categories. For both the categories and the form of their unfolding are, from the very beginning, of an inherently idealist character. Instead, a materialist reading must consist in carefully recognising which real determinations could be reflected by Hegel at certain stages of his idealist systematic dialectic. Evidently, the recognition of those determinations can only take place *vis-à-vis* the actual knowledge of those simpler forms of material reality. Thus, strictly speaking, the issue at stake is not simply to read the *Logic* from a materialist perspective. The question is rather to appropriate its 'use-value' to *rewrite it materialistically*, that is, to unfold the simpler determinations of material reality in their inner connection. Needless to say, this obviously exceeds the scope of this chapter. Here we just offered a discussion of the point of departure of such a materialist appropriation of the rational kernel of Hegel's *Logic*, which we have identified with his category of 'being-for-self'.[62] Our aim in this section was thus much more modest; the point was simply to show the intrinsically idealist nature of Hegel's systematic development in order to shed light on its difference from Marx's materialist approach. Let us therefore elaborate further on this point, through an examination of the general form taken by Hegel's systematic unfolding of categories.

Towards the end of the *Logic* Hegel discusses this question explicitly. 'What is to be considered here as method', he states, 'is only the movement of the

---

[62] On this we simply drew on the work of Iñigo Carrera, who fleshes out the discovery of the said point of departure – that is, affirming through self-negation of real material being – as strictly emerging as a result of materialist analysis in the sense discussed above (Iñigo Carrera 1992, pp. 3–5).

Notion itself … the *universal absolute activity*.'[63] However, this movement is not presented by Hegel as simply taking the generic form of affirmation through self-negation through which a self-determining subject realises its own immanent necessity. Instead, in so far as he conceives of it as a pure movement of thought striving for a fully developed mode of expressing its truth-content, he presents it as the unity of the *three moments* through which thought needs to pass in order to self-posit in such an adequate shape. Thus, he concludes, 'the whole form of the method is a triplicity'.[64] The movement of affirmation through self-negation, which as the simplest content of the 'immanent life' of any material object, constitutes the generic form taken by a materialist-dialectical unfolding, is represented by Hegel as the abstract sequence of an affirmation, a negation and, lastly, the negation of the negation. In other words, Hegel does not directly present the third moment, which is the only one that constitutes the effective material reality of the object. Instead, he firstly needs to posit the prior two 'imperfect' moments, which are just formal stages through which thought needs to go to grasp the 'truth' of the object, as if they were constitutive of the effective objective reality of the object itself. This 'triadic structure' of the absolute method, which derives from the idealist character of the Hegelian dialectic, is also eloquently criticised by Marx in *The Poverty of Philosophy*:

> So what is this absolute method? The abstraction of movement. What is the abstraction of movement? Movement in abstract condition. What is movement in abstract condition? The purely logical formula of movement or the movement of pure reason. Wherein does the movement of pure reason consist? In posing itself, opposing itself, composing itself; in formulating itself as thesis, antithesis, synthesis; or, yet, in affirming itself, negating itself, and negating its negation.[65]

In brief, what is rational in Hegel's dialectic, that is, its method of immanent development of the life of the subject-matter, appears inverted under the mystical form of the three moments of self-developing pure thought. Again, this mystical shell directly stems from the fact that Hegel's systematic dialectic does not ideally follow the immanent life of a concrete material object but an ideal one, namely pure thought. Hegel's 'mysticism' in the *Logic* therefore derives from being the *ideal reproduction of the ideal*. By contrast, in making analysis instead of abstraction, Marx's scientific method at no point leaves the concrete material object of investigation behind. No matter how abstract and far from its immediate sensuous existence the analytical process eventually takes him, *he remains firmly within the materiality of the object.* As a consequence, the moment of systematic synthetic unfolding cannot but be the ‘reproduction of the concrete by means of thought’.

---

[63] Hegel 1999 [1812–16], p. 826.

[64] Hegel 1999 [1812–16], p. 836.

[65] Marx 1976b [1847], p. 164.

Among all the places where Marx expounds this kind of materialist ideal reproduction, it is also probably in the first chapter of *Capital* where it can be found with utmost clarity and in a more ‘stylised’ form. Specifically, this reproduction only starts in section III of Chapter I, entitled ‘The value-form, or exchange-value’.[66] As argued elsewhere, strictly speaking the first two sections of that chapter are not part of the *synthetic* movement of the dialectical exposition but constitute its *analytical* prelude.[67] As we have seen, the analytic stage only separates a concrete form from a more abstract one, whose realised potentiality it carries within itself in the form of its own immanent potentiality. In this sense, the analytic stage does not ideally reflect the immanent self-movement of the object under consideration. It is therefore not about the *why* but about the *what.* Evidently, since the apprehension of real forms according to their relative degree of abstractness or concreteness ideally expresses the objective necessity (the real relations) residing in the object and are not the product of the subjective caprice or imagination of the scientist, the mere reference to the ‘what’ carries implicitly some hint of the ‘why’. Thus, if the dialectical analysis reveals that the value-form is the concrete form in which the objectification of the abstract character of private and independent labour affirms itself as an abstract form, the separation between the two already says something about the real relation involved. But this something is no more than, as it were, a ‘pointing out’, an external observation. The actual exposition of that inner connection between content and form – hence its explanation – takes place in the *synthetic* phase of *reproduction*, which faces the challenge of precisely showing that movement which the analysis was incapable of unfolding. This consists in ideally following the realisation of the discovered potentiality immanent in the commodity, namely value. From then on, the commodity ceases to be grasped in its exteriority as an ‘inert’ external object and the exposition starts to follow its self-movement as the subject of the development of those determinations previously discovered through analysis into ever more concrete forms.[68]

---

[66] Marx 1976c [1867], p. 138.

[67] See Starosta 2008 for a close examination of the structure of Marx's exposition in Chapter I of *Capital*. For a more detailed discussion of the methodological implications of Marx's ideal reproduction in general, see Iñigo Carrera 2007, 2013, and in this volume.

The unfolding of this movement spoken in 'the language of commodities'[69] is precisely what the ideal reproduction consists of. Value being the purely social power of the commodity, it cannot be immediately expressed in its sensuous corporeal materiality. As the capacity of the commodity to be exchanged for other different commodities, value can only be manifested in the social relation of exchange between commodities. Therefore, the value of a commodity necessarily expresses itself only in the use-value of the commodity that is exchanged for the commodity in question as its equivalent. In this way, value takes the concrete shape of exchange-value as its necessary form of manifestation. In its most developed form, value acquires independent existence as money and the expression of value in the particular commodity acting as money becomes determined as price. The opposition inherent in the commodity is thus externalised through the doubling of the commodity-form into ordinary commodities and money. The power of direct exchangeability of commodities negates itself as such to become affirmed as a social power monopolised by the money-form.

It is in the course of the movement of this reproduction, when seen from the point of view of its *qualitative content*, that the answer to the questions which the analytic stage was impotent fully to provide is given. In other words, it is the development of the expression of value that unfolds the explanation as to why the objectification of the abstract character of privately performed labour takes the social form of value or, to put it differently, why private labour is value-producing. In a nutshell, the issue comes down to the fact that it is only the expression of value that progressively reveals to us the problem that the commodity-form of the product of labour is meant to solve. We are referring to the mediation in the establishment of the unity of social labour when performed in a private and independent manner. And since this unity becomes condensed in the money-form, it is the unfolding of its determinations, synthesised in the peculiarities of the equivalent-form and derived from its general determination as the form of immediate exchangeability, that provides the answer to the question as to why privately performed socially necessary labour must produce value.

Note, however, that the properly *dialectical* unfolding of the movement of this qualitative determination is, in essence, already achieved with the simple form of value. The subsequent passage to the other, more developed forms of value is simply a formal movement that merely generalises and makes explicit the qualitative content already expressed in the simple form (namely, the immanent necessity for value to acquire an outward, differentiated mode of existence). In other, more polemic terms, the sequence of the more developed forms of value as such is not structured according to an immanent necessity of those forms. As Iñigo Carrera puts it, the sequence of forms of value 'does not imply a simpler form [of the exchange-relation] engendering a more concrete one. Instead, the unfolding of the former's necessity evidences the necessity of the existence of the latter.'[70] This is, we think, the actual meaning behind Marx's remark that 'the whole mystery of the form of value lies hidden in this simple form'.[71]

---

[68] Iñigo Carrera, in this volume, p. 74ff.

[69] Marx 1976c [1867], p. 143.

In light of this, we can now bring out a crucial difference between Marx's and Hegel's respective ideal reproductions. Specifically, Marx's ideal reproduction of the commodity-form simply follows the realisation of its immanent necessity to 'affirm' by developing a more concrete mode of existence as money (that is, through self-negation). However, unlike Hegel's idealist method of reproduction in the *Logic*, in order to do this Marx does not need to mediate this exposition with a prior positing of the inadequate forms in which *thought conceives of* those immanent determinations of the commodity which drive them to self-movement. For Marx, those inadequate conceptualisations of the inner determinations of the commodity are not *constitutive* of the objective reality of the commodity itself, and have therefore no place in the *systematic unfolding of its immanent life*. Instead, they are seen by Marx as (*fetishised*) *appearances* through which non-dialectical thought grasps those determinations in their sheer exteriority. In any case, those apparent relationships between real forms should have been already examined and *ruled out* by the investigation in the previous methodological phase of *analysis*. In Marx's presentation, when discussions of those essentially *ideological* scientific representations of real relations do occur, they tend to have status of an *external remark*, and are deliberately located *after* the immanent determination has been unfolded.

4 Conclusion

This chapter offered a contribution to the debate on the methodological connection between Hegel's *Logic* and Marx's *Capital* through a discussion of the rational kernel and mystical shell found in the former. Very briefly put, our argument was that in that work Hegel managed to discover the simplest form of the real, namely, the movement of self-determination of the subject. As a consequence, he correctly presents the method of science as the systematic unfolding of the immanent life of the subject-matter. Against Colletti, we have argued that this is the rational kernel to be found in his work and it is not inherently tied to absolute idealism. However, instead of taking the simplest form of real material being as point of departure, his exposition begins with the simplest thought-form ('pure being'). The systematic dialectic that follows therefore inevitably unfolds a whole series of redundant categories which, from a materialist standpoint, correspond to the immanent necessity of pure thought only. In other words, they do not express any objective determination of real material being. This is the *Logic's* mystical shell.

---

[70] Iñigo Carrera, 2013, pp. 58–9.

[71] Marx 1976c [1867], p. 139.

We have also argued that an immediate reason behind that spurious starting point resides in his methodological procedure of 'extreme' formal abstraction, which arbitrarily casts aside all particular determination until reaching a wholly empty universal, namely, the *thought* of being. By contrast we have seen that Marx finds a materialist alternative to formal abstraction in dialectical *analysis*. Instead of the sheer abstraction from apparently contingent features of objects, Marx's analysis moves by searching for the real more abstract or simple content of the concrete form he is immediately facing. The procedure is then repeated by further analysing each of the relatively more abstract determinations discovered, until reaching the simplest immanent content of the initial concrete. Materialist analysis therefore remains firmly within the real object through and through.

Three main conclusions can be drawn from this with regard to the current debate on Marx's dialectical method in *Capital*. Firstly, in so far as the ideal reproduction of the concrete by means of thought needs to reflect ideally the *specific* immanent determinations of the subject-matter, this method does not proceed, as Diamat would have it, by *applying* the 'general laws of dialectics' or 'abstract logical structures' onto more concrete domains of knowledge. In this sense, the movement of affirmation through self-negation must not be turned into an absolute *general principle* that needs to be *applied* to *economic categories*. As the form of movement, the 'inner life', of the concrete object that we want to appropriate by means of thought, it has to be followed in its specific modes of existence and development. This is why, for instance, Marx's *Capital*, as a critique of political economy, is not (*pace* Engels) an application of dialectical logic to political economy, but the ideal reproduction of the real determinations of capital as the alienated social subject of bourgeois society, starting with its simplest mode of existence, namely, the commodity.

Secondly, the problem with Hegel's unfolding of categories in the *Logic* does not simply reside in his absolute idealism, but fundamentally in the methodological procedure by which he arrives at its point of departure and the form taken by the subsequent synthetic reconstitution of the unity of the immanent determinations of his object. In other words, even if we took on board Smith's point that Hegel considered the independent existence of an objective reality outside thought, his systematic dialectic would be still defective from a materialist standpoint. As a consequence, it should not be simply taken over but first needs to be thoroughly 'rewritten' materialistically.

Finally, although not explicitly addressed in this chapter, it does follow from our discussion that the structures of the *Logic* and *Capital* cannot be treated as homologous as in Arthur's view. As the previous section has shown, the general form of motion of the synthetic stage of reproduction differs between the two works, with Hegel's idealist dialectic ridden with superfluous formal steps in the argument which have no place in Marx's materialist approach.

In sum, a materialist appropriation of the methodological insights found in the *Logic* for the critique of political economy must carefully cast aside its mystical shell.

Abstract

This article aims to contribute to the literature on Marx's systematic-dialectical method through a critical reading and discussion of the significance and presentational 'architecture' of the section on commodity fetishism in the dialectical sequence of form-determinations in *Capital*. In order to undertake this task, the paper firstly explores the content and expositional structure of the first three sections of Chapter 1 of *Capital*. This sets the stage for a methodologically-minded close examination of Marx's presentation of the fetish character of the commodity, which shows that there is a precise systematic sequence which gives unity to the flow of his argument within the section on 'The Fetishism of the Commodity and its Secret'. The conclusion is that only through a proper grasp of the dialectical method can the full systematic significance and implications of Marx's account of commodity fetishism be uncovered.

Keywords

commodity fetishism – systematic-dialectical method – subjectivity – value-form

Introduction[1]

Ever since the publication of works such as Rubin's *Essays on Marx's Theory of Value*[2] or Lukács's *History and Class Consciousness*,[3] the emphasis on Marx's analysis of commodity fetishism has been a hallmark of critical traditions of Marxism. In effect, according to those traditions, commodity fetishism is the cornerstone upon which the understanding of Marx's mature works as a *critique* of political economy (as opposed to political economy or economics) depends.[4] While there is no doubt that the fetishism of commodities plays a fundamental part in Marx's critique of political economy, the question is, once we accept this premise, what are the precise meanings and implications of such a notion for the scientific comprehension of capitalist society as a whole, and, more concretely, for the proletarian political action through which the movement of capital realises its own annihilation? Here, the mere reference to the centrality of the historicity of bourgeois social forms and their fetishistic character does not suffice to grasp the critical and revolutionary nature of the critique of political economy.

---

[1] In keeping with the Fowkes translation utilised for the preparation of this article and with its widespread use in the literature, I will use the terms 'commodity fetishism' and 'fetish-like character of the commodity' interchangeably, in both cases to refer to the essential substantive meaning of the said phenomenon, namely, the real inverted existence of the social determinations of privately-undertaken human labour as an objective 'supersensible' power of its product (i.e. value). This primordial determination and its social constitution should be distinguished from a more concrete aspect of this very same inverted consciousness of the commodity producer, which I also discuss below: when she faces this process of inversion in an already constituted form or as a *fait accompli*, it takes the *purely social* power of exchangeability of the commodity as if it were a *natural property* of the product of labour. In other words, it is also an apparent, mystified or illusory consciousness. In this sense, some recent commentators (Bellofiore 2014; Ehrbar 2010; Schulz 2012) have perceptively pointed out that the standard English translation is rather problematic. In effect, it overlooks that Marx systematically assigned the term 'fetish-like character' (*Fetischcharakter*) to the essential determination consisting in the real inversion of human social powers as attributes of things, while he reserved the term 'fetishism' (*Fetischismus*) for the illusory consciousness that naturalises this social power of the commodity. Now, although I do not dispute the pertinence of these exegetical observations, they are in the end of a *terminological* nature. In my view, as long as the content and meaning of each aspect of the phenomenon under consideration are clearly established and defined (as I believe this paper does), and given its usual adoption in contemporary Marxist debates to refer to its essential substantive determination, the continued usage of the admittedly-problematic term 'commodity fetishism' is harmless.

A first issue that arises therefore concerns the varied substantive understandings of commodity fetishism in the history of Marxism. In a recent doctoral dissertation, O'Kane offers a concise and useful typology of the different meanings attached to the term 'fetishism' in the diverse readings and traditions of Marxian theory.[5] Firstly, there is the interpretation of 'fetishism as false consciousness', which can be traced back to the 'orthodox' or 'traditional' Marxist reading by Kautsky,[6] but which can be also found in more recent times among so-called 'analytical Marxists'.[7] Secondly, there is the Althusserian conception, which, in its earliest version, quite simply rejected Marx's discussion of commodity fetishism (insofar as it was seen as a residue of the Hegelian influence on the young Marx).[8] Later, Althusser qualified his early assessment and came to accept the notion of fetishism as a false conception that 'veils' the system of capitalist social relations with a relation between things.[9] Thirdly, this typology identifies the notion of 'fetishism as reification', which can be traced back to the main exponents of the so-called Western Marxist tradition (in particular, Lukács in *History and Class Consciousness* and Weberian readings of the Frankfurt School).[10] Fourthly, there is the interpretation of 'fetishism as alienation', which characterises the classic Marxist Humanist conception that emerged after the publication of the *1844 Paris Manuscripts* and which stressed, against Althusser's 'epistemological break', the continuity between the 'Hegelian young Marx' and the 'mature' Marx of *Capital* (for instance, the work of Marcuse, Lefebvre and Fromm). Finally, O'Kane identifies a fifth strand that he labels 'fetishism as value', and which broadly corresponds to the tradition of value-form theory or 'form-analysis'. In this approach, commodity-fetishism is understood as the historically-specific inverted social constitution of thing-like forms of social mediation that configure an impersonal 'system of objective compulsion', and which reduces the existence of human beings to its personifications.

[10] For a critique of these Weberian understandings of commodity fetishism, see the seminal work by Clarke 1991.

This article offers a detailed critical reconstruction of Marx's account of commodity fetishism which, broadly speaking, can be substantively located within this latter tradition that reads section 4 of Chapter 1 of *Capital* as a critical investigation of the social constitution of value-objectivity out of the social form of capitalist social relations of production. Although I believe that the paper does also provide a novel and original reading in this respect (specifically, concerning the connection between value and consciousness), it is not in the substantive issues surrounding commodity fetishism that the main contribution of the paper lies. Rather, my aim is fundamentally at the level of *method*. More concretely, the paper discusses the precise role and place of commodity fetishism in light of Marx's *systematic-dialectical* exposition in *Capital* and argues that the specific form of the dialectical method is fundamental in this respect. Yet both aspects are immanently related: a proper grasp of the substantive *content* of commodity fetishism can only result from a correct understanding of the very *form* of Marx's process of cognition.

The need to reconsider Marx's presentation of the commodity-form in Chapter 1 of *Capital* through a reassessment of his dialectical method (in particular, its connection to Hegel's *Science of Logic*) has been widely recognised by a growing number of scholars, especially within the ranks of the so-called 'New Dialectics' or 'systematic-dialectical' approach. In effect, the last 20 or 25 years have witnessed a renewed interest in Marx's dialectical method and its implications for value theory.[11] Although there are various particular controversies over the precise nature of this connection, most contributions agree that the structure of the argument in *Capital* is organised in a dialectical form which, at the very least, can be said to draw formal inspiration from the general form of movement of categories that Hegel deploys in his *Logic*. Thus Marx's presentation is seen as involving a (synthetic) movement from the more abstract or simple form-determinations of the subject-matter (namely, capital) to the increasingly more concrete or complex forms in which it moves and eventually manifests in 'empirical' reality, thereby culminating in the intellectual reproduction of capital as the unity of those many determinations. Inasmuch as the transition from one economic form to the next is seen as being driven by the development of the contradictions immanent in each of them, their relationship is generally deemed as internal and grounded in dialectical necessity, in contrast to the externality and unmotivated shifts that inevitably result from the use of formal logic.

---

[11] See, among others, Murray 1988; Reuten and Williams 1989; Smith 1990; Moseley (ed.) 1993; Moseley and Campbell (eds.) 1997; Arthur 2002; Albritton and Simoulidis (eds.) 2003; Moseley and Smith (eds.) 2014.

Now, despite all the light that these works have cast on the form of Marx's argument, I think that two important gaps can be found in this literature. In the first place, they have been mainly focused on the *synthetic* aspects of Marx's dialectical presentation (i.e. on the exposition of the dialectical movement from the 'abstract to the concrete'). In this sense, it could be argued that this literature has glossed over the peculiar role of the *phase of analysis* in Marx's dialectical investigation generally and in his presentation in *Capital* in particular.[12] Furthermore, these scholars have not paid sufficient attention to the *specific form of the analytical process within dialectical thought*.[13] In the second place, as far as I am aware, works coming from the 'New Dialectics' approach, which are those that emphasise the dialectical structure of Marx's argument (and hence the necessity of the sequence of form-determinations), tend not to discuss the precise *systematic* role and place of commodity fetishism in the exposition in *Capital*. In other words, although these works obviously do highlight its centrality for the critique of political economy, they do not thematise the question of the systematic necessity for the dialectical presentation in *Capital* to address, at the specific point of section 4 of Chapter 1, the fetish-like character of the commodity. Moreover, and in stark contrast with the attention given to the order of Marx's dialectical exposition in the first three sections of Chapter 1, most works seldom inquire into the existence of a systematic sequence which would give unity to the flow of his argument *within* the section on 'The Fetishism of the Commodity and its Secret'.[14]

---

[12] The distinction between analysis (in the sense of dissection of the 'whole' into 'parts' or 'identification of differences') and synthesis (in the sense of reconstitution of the 'unity' of the whole) is not peculiar to dialectics. As I argue below, what sets the latter apart from formal-logical methodologies is the specific *form* taken both by the analytical and synthetic processes in dialectical thought. Zelený 1980, Chapter 10, provides a concise discussion of the different meanings of analysis and synthesis in science and philosophy, which also traces back their intellectual lineage.

[13] Starosta 2008. These other aspects have not been entirely absent in the literature (see, for instance, Murray 1988, pp. 148–50). However, they came up in the debate among 'new dialecticians' relatively late (Murray 2002; Reuten 2000) and have not been pursued any further until recently (see Reuten 2014, who does address in great detail the connection between analysis and synthesis, and that between inquiry and presentation, in systematic dialectics). In this sense, Ollman's criticism of the systematic-dialectics literature, that these authors tend to focus one-sidedly on Marx's method of *exposition* at the expense of his method of *inquiry*, is, to some extent, pertinent (Ollman 2003, pp. 177–80). However, it seems to me that Ollman is somewhat unfair in his claim that the systematic-dialectics approach *restricts* Marx's method to a strategy of presentation and simply neglects it as a mode of inquiry. Be that as it may, it is my view that compared to the light thrown on the synthetic aspects of Marx's method of presentation, the nature of the relation between analysis and synthesis in the presentation and the way in which this relates to the formal determinations of the dialectical inquiry, have not been explored with the same depth and clarity.

My aim in this article is therefore to contribute to filling these gaps in the literature through a critical reading and discussion of the significance and presentational 'architecture' of the section on commodity fetishism in the dialectical sequence of form-determinations in *Capital*. In order to undertake this task, the paper firstly explores the content and expositional structure of the first three sections of Chapter 1 of *Capital*. This will set the stage for the discussion in the other sections of this article, in which I offer a methodologically-minded close examination of Marx's presentation of the fetish character of the commodity. As the discussion will hopefully make evident, only through a proper grasp of the dialectical method can the full systematic significance and implications of Marx's account of commodity fetishism be uncovered.[15]

---

[14] Heinrich 2012, in his introduction to the three volumes of *Capital*, is a partial exception. Thus, he offers a very detailed and rigorous commentary on each paragraph of the section on commodity fetishism which, at least implicitly, implies the acknowledgement that there is a systematic guiding thread structuring the flow of Marx's argument. However, he does not connect the latter with the form of motion of the dialectical presentation. Furthermore and oddly enough, without offering any explicit reason he introduces the commentary on the section on commodity fetishism after his discussion of Chapter 3 on the functions of money. This undermines his otherwise insightful attempt at showing the systematic connection between the first two chapters of Volume I. As argued below in this article, the section on commodity fetishism is a necessary mediating link between the commodity and the action of commodity-owners in the process of exchange. Still, the rigour of Heinrich's commentary markedly sets it apart from David Harvey's popularising reading in his recent *Companion to Marx's Capital* (see Harvey 2010). In this recent book, Harvey characterises the writing style of the section on commodity fetishism as 'literary … evocative and metaphoric, imaginative, playful and emotive, full of allusions and references to magic, mysteries and necromancies', which he contrasts with the 'dull accountancy style of the previous sections' (Harvey 2010, p. 38). Although probably a humorous remark in a book based on lectures to postgraduate students, this characterisation of the passage from the 'language of commodities' to the 'language of human beings' has the unintended consequence of trivialising (and thus obscuring) the systematic necessity of such a transition and, as a consequence, the significance of commodity fetishism in the dialectical development of form-determinations.

[15] These claims are more fully elaborated in Starosta 2016.

Outline of the Structure of Marx's Presentation in the First Three Sections of Chapter 1 of *Capital*[16]

The Phase of Analysis in Sections 1 and 2 of Chapter 1 of Capital

In the *Marginal Notes on Adolf Wagner* Marx states unambiguously that he starts the exposition in *Capital* with the immediate observation of the commodity as simplest *concretum* in which capital-determined social labour is expressed in order to develop the real determinations specific to this social form.[17] In Marx's own words, he begins with the immediate observation of 'the simplest social form in which the labour-product is presented in contemporary society'.[18] From this starting point, Marx proceeds by taking the individual commodity 'in his own hand' and analysing 'the form determinations that it contains as a commodity and which stamp it as a commodity'.[19] These form-determinations Marx initially discovers by looking at the use-value of the individual commodity, which in capitalist societies acts as bearer of a second, *historically specific* attribute of the products of labour, namely, *exchange-value*. Marx's exposition thereby initially revolves around the (dialectical) *analysis* of that historically specific power of the commodity.

As happens with every real form, the first thing he encounters when facing the exchangeability of the commodity is its *immediate manifestation* – the quantitative relation 'in which use-values of one kind exchange for use-values of another'.[20] The next step in the analysis of exchangeability is the uncovering of the *more abstract form* (hence the *content*) behind that specific formal attribute of the commodity, this being the only way in which we can penetrate through the concrete form in which an immanent determination presents itself. Thus, the further analysis of the commodity reveals that exchange-value is actually the 'mode of expression' or 'form of manifestation' of a content distinguishable from it – value – the substance of which resides in the abstract labour congealed or materialised in the commodity.

Having discovered the materiality of the qualitative content of the 'ghostly objectivity' of value, Marx briefly discusses its quantitative determination: the *magnitude* of value is determined by the *socially-necessary* labour time required for the production of commodities. This means that the objectification of the abstract character of labour is socially represented in the form of value only inasmuch as it satisfies two conditions: first, that it corresponds to the technologically normal conditions of production prevailing in society,[21] and, second, that it can satisfy a social need,[22] regardless of whether these needs arise from 'the stomach or the imagination'.[23]

[16] This section summarises arguments elaborated more fully in Starosta 2008.

[17] Marx 1975, p. 198.

[18] Ibid.

[19] Marx 1976a, p. 1059 (translation amended).

[20] Marx 1976c, p. 126.

As argued elsewhere, in opposition to the claims of a great deal of contemporary literature on Marx's theory of the value-form, I think that the (analytic) search for the specific determinations of the commodity is evidently not achieved with the discovery of abstract labour as the substance of value.[24] Quite to the contrary, that very specificity seemed to have slipped through Marx's fingers. In effect, although he found the specific attribute of the commodity in its value, when he moved to account for its substance he ended up with something which bears no specifically-capitalist character: 'merely congealed quantities of homogeneous human labour, i.e. of human labour power expended without regard to the form of its expenditure'.[25] This is the reason why Marx still carries on with the analytic search for the '*form determinations* that it contains as a commodity and which stamp it as a commodity'.[26]

---

[22] Marx 1976c, p. 131.

[23] Marx 1976c, p. 125. For a more extended discussion of the meaning of 'socially necessary labour', see Kicillof and Starosta 2007a.

[24] As a reaction to the ahistorical, Ricardian reading of Marx's account of the value-form, the 'new consensus' tends to see abstract labour as a purely historical, specific social form. See, among others, De Angelis 1995; Postone 1996; Reuten 1993; Arthur 2001; Bellofiore and Finelli 1998; Kay 1999; Saad-Filho 1997; Mohun and Himmelweit 1978; de Vroey 1982; Eldred and Haldon 1981; Bellofiore 2009; Heinrich 2009; Mavroudeas 2004; McGlone and Kliman 2004; Roberts 2004. I have developed a more extended critique of this new consensus in Kicillof and Starosta 2007a and 2007b. Here I can only offer some very brief remarks on this issue. Abstract labour is a generic material form, a 'productive expenditure of human brains, muscles, nerves, hands etc.' (Marx 1976c, p. 134). What is specific to capitalist society is the role it plays by being determined as the substance of the most abstract form of objectified social mediation, namely: value. In other words, at stake here is the *movement of the contradiction* between the generic, physiological materiality of abstract labour and its historically-specific *social* determination as the substance of value deriving from the *private* character of labour in capitalism. See also Carchedi 2009, Carchedi 2011a, pp. 60–74, and Robles Báez 2004, for a similar argument. Murray 2000 comes very close to recognising this through the distinction between 'physiological' abstract labour and 'practically abstract' labour, thus shifting his thinking from the earlier perspective adopted in Murray 1988. The debate on the nature of abstract labour has not been settled and has continued in more recent times. See Bonefeld 2010 and 2011; Carchedi 2011b; Kicillof and Starosta 2011.

[25] Marx 1976c, p. 128.

This leads Marx's dialectical analysis to give closer scrutiny to the *labour that produces commodities* in the following section of Chapter 1. As any attentive reader could tell, the analytic process continues and it is only in *section 2 on the dual character of labour* that Marx finally finds the historically-specific form of social labour that produces commodities and, hence, value. The commodity, Marx eventually concludes, is the objectification 'of mutually independent acts of labour, performed in isolation'.[27] In other words, it is the 'labour of private individuals who work independently of each other',[28] or *private and independent labour*, which constitutes the specifically-capitalist form of labour or productive activity. The analytic process completes the search for the specific determinations of the value-form by revealing that the attribute of general exchangeability of the commodity springs from the abstract or general character of socially-necessary *privately performed* labour materialised in it. The value-form, then, becomes known in its essential determination as the *objectified or reified expression of the social character of the individual labour of private and independent producers*. Its objectivity is thus revealed to be wholly social, without an atom of 'matter' entering into it,[29] i.e. it is the purely social representation of the 'physiological' materiality of objectified, privately-undertaken socially-necessary abstract human labour that constitutes its substance.

Now, as is widely acknowledged in the literature, the sequence at that initial stage of Marx's argument (i.e. in the course of the transition from section 1 to section 2 of the first chapter) consists in going from *form* to *content*. However, the crux of the matter does not simply reside in realising this (which, at any rate, is explicitly announced by Marx himself in the first pages of Chapter 1), but in grasping the precise way in which properly dialectical analysis discovers the content behind the form and, therefore, their inner connection.[30]

In contrast to the conventional scientific method, dialectical thought analyses a concrete form by, first of all, facing it as embodying a qualitative potentiality for transformation, and second, by grasping that qualitative potentiality as the concrete form in which a more abstract form realises its own qualitative potentiality, that is, its real necessity. Thus the dialectical ideal appropriation of the universe of different real forms does not proceed through an identification of the distinctiveness of forms on the basis of the degree of repetition of certain attributes. Rather, it analytically separates the different forms by discovering as *immanent* in a particular concrete form the realised potentiality of another real form, which is abstract with respect to the first one, but concrete with respect to another form of which it is the realised potentiality. For instance, value, as the specific immanent qualitative potentiality of the commodity as a generally-exchangeable 'social thing', is discovered as the common attribute that is immanent in the *singular* quantitative exchange relation between two different use-values that constitutes the immediate appearance of exchange-value. The latter is thereby revealed as the necessary concrete form in which value is immanently realised. In turn, value is uncovered as the concrete form in which the potentiality of privately-performed socially-necessary abstract labour as a productive action (i.e. as an individual expenditure of labour-power immanently determined as an organ of the social metabolic process) is realised in its result or product.

---

[26] Note that had abstract labour as such constituted the specificity of value-positing human action, Marx's analytical search would have come to an end.

[27] Marx 1976c, p. 132.

[28] Marx 1976c, p. 165.

[29] Marx 1976c, p. 138.

[30] Iñigo Carrera 2012.

Thus, while conventional scientific method grasps the general determination of real forms as immediate affirmations and hence self-subsistent entities, the distinctive mark of the process of analysis in dialectical research is to grasp, *in the same analytic movement*, both the concrete form under scrutiny and the more abstract one of which the former is the developed mode of existence. In other words, dialectical thought grasps each form as the affirmation through self-negation of another, more abstract one (hence, as subjects of their own movement). This analytical procedure must be then renewed for those other more-abstract forms, but now treated as the real concrete form whose inner content the research is trying to uncover. Only once all those inner form-determinations have been uncovered through analysis should the investigation undertake the 'return journey' through which those abstract determinations, now in their self-movement, lead to 'the reproduction of the concrete by means of thought'.[31]

The Synthetic Phase of Ideal Reproduction Proper

In a nutshell, the discussion above showed that, strictly speaking, the first two sections of Chapter 1 of *Capital* are not part of the *synthetic* movement of the dialectical exposition but constitute its *analytic* prelude. As we have seen, the analytic stage only separates a concrete form from a more abstract one, whose realised potentiality it carries within itself in the form of its own immanent potentiality. In this sense, the analytic stage does not ideally reflect the immanent self-movement of the object under consideration. It is therefore not about the *why* but only about the *what*. Evidently, since the apprehension of real forms according to their relative degree of abstractness or concreteness ideally expresses the objective necessity (the real relations) residing in the object and is not the product of the subjective caprice or imagination of the scientist, the mere reference to the 'what' carries implicitly some hint of the 'why'. But this something is no more than, as it were, a 'pointing out', an external observation. The actual exposition of the unity between content and form – hence its explanation – takes place in the *synthetic* phase of *reproduction*, which faces the challenge of precisely showing that movement which the analysis was incapable of unfolding: the necessity of the realisation of that (more abstract) determination in its more concrete forms of existence.

---

[31] Marx 1993, p. 100. Note that this specific form of motion of analysis and synthesis in dialectical thought applies not only to the moment of exposition or presentation but, primordially, to the moment of inquiry as well. See Iñigo Carrera 2013.

In the specific context of the structure of Chapter 1 of *Capital*, this synthetic movement consists in ideally following the realisation or actualisation of the attribute of exchangeability (i.e. value), which is the potentiality that was analytically uncovered as immanent in the commodity. From then on, the commodity ceases to be grasped in its exteriority as an 'inert' external object and the exposition starts to follow its self-movement as the subject of the development of those determinations previously discovered through analysis into ever more concrete forms.[32] Specifically, this reproduction only starts in section 3 of Chapter I, entitled 'The value-form, or exchange-value' and consists of the unfolding of the content of this movement albeit as spoken in 'the language of commodities'.[33]

In effect, insofar as value is the purely social power of the commodity, it cannot be immediately expressed in its sensuous corporeal materiality. As the capacity of the commodity to be exchanged for other different commodities, value can only be manifested in the social relation of exchange between commodities. Therefore, the value of a commodity necessarily expresses itself only in the use-value of the commodity that is exchanged for the commodity in question as its equivalent. In this way, value takes the concrete shape of exchange-value as its necessary form of manifestation. In its most developed form, value acquires independent existence as money, and the expression of value in the particular commodity acting as money becomes determined as price. The opposition inherent in the commodity is thus externalised through the doubling of the commodity-form into ordinary commodities and money. The power of direct exchangeability of commodities negates itself as such to become affirmed as a social power monopolised by the money-form.

---

[32] Iñigo Carrera 2014.

[33] Marx 1976c, p. 143.

It is in the course of the movement of this ideal reproduction, when seen from the point of view of its *qualitative content*, that the answer to the questions which the analytic stage was impotent fully to provide is given. In other words, it is the development of the expression of value that unfolds the explanation as to *why* the objectification of the abstract character of privately performed labour takes the social form of value or, to put it differently, why private labour is value-producing. In a nutshell, the issue comes down to the fact that it is only the expression of value which progressively reveals the problem that the commodity-form of the product of labour is meant to solve. I am referring to the mediation in the establishment of the unity of social labour when performed in a private and independent manner. And since this unity becomes condensed in the money-form, it is the unfolding of its determinations, synthesised in the peculiarities of the equivalent form and derived from its general determination as the form of immediate exchangeability, that provides the answer to the question as to why privately performed socially-necessary abstract labour must produce value.

In sum, in capitalist society the unity of social labour thus becomes socially represented in the form of the particular private product that the rest of commodities separate as their general equivalent and which eventually ossifies in the money-form. In tracing the genesis of the latter through the ideal reproduction of the expression of value, the synthetic stage of the dialectical exposition thereby positively unfolds the determinations of that which the analytic process could only *point out*. Namely, that the value-form of the product of labour is the materialised general social relation of human beings in the capitalist mode of production and, therefore, the reified *social subject* of the *form* in which the social process of production of human life attains unity in this historical stage of its development.

It is only at this juncture that Marx introduces the fundamental discussion of the fetish character of commodities. The question that immediately arises, and which is hardly addressed in the literature, is *why only and precisely then?* I think that the answer to this question is inseparable from the issue about the determinate content of the section on commodity fetishism and its place in the overall structure of Marx's exposition in *Capital*. The object of the next section, then, is to proceed to deal with these questions.

The Immediate Object of Exposition of the Section on Commodity Fetishism and its Systematic Place and Significance

In order to clarify the issue, let me get straight to the point and pose the fundamental question which underlies the proper comprehension of the systematic place and significance of the section on commodity fetishism in the structure of Marx’s presentation, namely, from the point of view of the dialectical method, what is the immediate object of the exposition in that section? As Iñigo Carrera points out,[34] those pages fundamentally develop the determinations of the alienated consciousness of the commodity producer. Or, better stated, they unfold the determinations of the alienated consciousness as such which, therefore, becomes *explicitly expounded* as an alienated consciousness. This is because, in reality, the whole of Chapter 1 (and, actually, the whole of *Capital*) has as its object the alienated consciousness of the commodity producer in the different, ever-more-concrete modes of existence (both the forms of *objectivity* and *subjectivity*).[35] However, the text starts out not with the alienated consciousness in and for itself, but with its most general *objectified* form of existence, namely, the commodity. Although the commodity *will prove to be* the alienated consciousness of the commodity producer, it is not yet known to be such at the beginning of the dialectical presentation. The commodity, not its producer, is thus the immediate subject of the determinations unfolded in the first three sections of Chapter 1.

---

[34] Iñigo Carrera 2007, pp. 260–1.

[35] See Starosta 2016, Chapter 6, for an in-depth elaboration on this admittedly polemical claim. For the sake of brief further clarification, however, a few additional words are in order. If the value-objectivity is, as argued below, the fetishised form in which the private producer unconsciously posits her own immanent social determinations as apparently autonomous powers of the product of labour, it follows that the further concrete forms assumed by the value-form, which is what the rest of *Capital* unfolds, must also be further developments of this initial simplest determination. Now, insofar as with ‘the metamorphosis of commodities’ the latter develop and acquire new determinations, this process ‘transforms the commodity-owners as well, and alters the social role they play in relation to one another’ (Marx 1987, p. 371). Thus, as this simplest objectified form of social mediation (the commodity/value) self-develops and changes, commodity owners ‘who represent these changed relations, acquire new economic characteristics’, i.e. they ‘change skin’ and emerge from the circulation process wearing different ‘character masks’ from those with which they entered. More specifically, as the systematic-dialectical presentation progresses, it reveals that the commodity with which it started actually proves to be the most abstract form of capital as self-valorising value. Its personification, the ‘commodity producer’, is concomitantly transformed. In the circulation process, commodity-owners become differentiated into owners of money-as-capital (capitalists) and owners of the commodity labour-power (wage-labourers). Upon the purchase of the labour-power of the doubly-free labourer, these two personifications establish an antagonistic direct social relation in the immediate process of production throughout the duration of the working day, in which the worker renders surplus-labour and valorises capital under the command of the capitalist. In other words, the capitalist personifies

Conversely, in the section on commodity fetishism, Marx turns his attention to the reasons why the products of private labour appear, to the producers themselves, as bearers of those reified powers whose autonomised self-movement he ideally reproduced through the expression of value contained in the exchange-relation. Having discovered behind the power of exchangeability of commodities the historically specific form in which capitalist society resolves the social organisation of the organic unity of human life, the exposition needs to explain why the producers, the actual subjects whose material reproduction is at stake, must represent that process in their consciousness in such a mystical and fetishistic form. The transition is, then, from the *formal* subject of the value-determinations, i.e. the commodity, to the *material* subject, i.e. the human individual.

In this respect, it could be said that the section on commodity fetishism opens a kind of new presentational (sub)node, which, in turn, will prove to be a necessary mediation for the determinations to be unfolded in Chapter 2 on the process of exchange. This is the case insofar as the section on commodity fetishism focuses on the determinations of the consciousness of the commodity producer analytically separated from the human action it regulates in the process of exchange. In other words, it expounds the determinations of consciousness mainly with regard to its *form*. Once Marx has established the historical formal determinations of human consciousness, in Chapter 2 he can then follow the mode in which the latter moves in the realisation of the general social relation, i.e. in its unity with action as conscious practice in the sphere

---

the privately-undertaken conscious organisation and direct control of the labour process performed by the wage-worker, whilst the latter personifies its execution proper. Thus, the simplest *systematic* (i.e. not historical) figure of the commodity producer with which the presentation started, which concentrated the personification of the unity of the conscious organisation and execution of privately-undertaken social labour, 'doubles' into capitalist and wage-worker, with those two roles in the direct production process now 'polarised' between these two different 'character masks'. The simplest determinations of value-positing are thereby not abstractly negated at the level of abstraction of the capital-form but 'sublated' (i.e. preserved through their self-negation). In sum, and in response to one of the referees' comments, what is said of the 'commodity producer' applies to all participants in a commodity-producing society.

of circulation (which is the phase of material reproduction in which human individuals *directly* confront, albeit as 'representatives of commodities', the manifestation of the general unity of social labour *indirectly* established behind their backs).[36]

As corresponds to the nodal structure of Marx's exposition, he starts the section on commodity fetishism with an immediate observation: 'A commodity appears at first sight an extremely obvious, trivial thing'.[37] However, very quickly he develops the analytic movement which brings us to the inner determinations of the commodity discovered in the previous section. In effect, Marx points out that although it immediately appears as a trivial thing, the commodity is in reality an entity full of metaphysical subtleties, a sensible/suprasensible being with the fantastic power of being transformed into another use-value without even touching its materiality.[38] On the other hand, at this stage of the process of cognition, we already know where to find the source of such mysticism; it must derive from the commodity-form itself, i.e. from its character as the reified mediator in the establishment of the unity of the social character of private labour. In the commodity, all the qualitative and quantitative determinations of social labour appear to the material subject of this activity as objective attributes of its product.

> Whence, then, arises the enigmatic character of the product of labour, as soon as it assumes the form of a commodity? Clearly, it arises from this form itself. The equality of the kinds of human labour takes on a physical form in the equal objectivity of the products of labour as values; the measure of the expenditure of human labour-power by its duration takes on the form of the magnitude of the value of the products of labour; and

---

[36] And even at that level, the alienated action that personifies the realisation of the necessity of the commodity to establish an exchange-relation is still abstract and is part of what Marx calls, in the *Contribution to the Critique of Political Economy*, the 'theoretical phase of circulation' of commodities, 'preparatory to real circulation' (Marx 1987, p. 303), which can only take place once, 'as a result of establishing prices, commodities have acquired the form in which they are able to enter circulation' (Marx 1987, p. 323). By this Marx means the ideal reproduction of the determinations of the circulation of commodities which constitute the premises of its actual movement. This 'theoretical circulation' comprises Chapters 1 and 2, and the first section of 3 (the functions of measure of value and standard of prices). Only then is the actual circulation of commodities reproduced in thought, revealing the subsequent functions of money not as its preconditions, but as its concrete forms.

[37] Marx 1976c, p. 163.

[38] Ibid.

> finally the relationships between the producers, within which the social characteristics of their labours are manifested, take on the form of a social relation between the products of labour.[39]

In the passage above, Marx is simply bringing together the results reached by the ideal reproduction of the form-determinations of the commodity in the previous three sections of Chapter 1. However, the dialectical exposition has so far uncovered this essential content of the commodity-form purely in terms of the search for the latter's immanent social determination as an exchangeable entity. As I shall argue in more detail below, the form-determinations of the commodity must now be revisited from the perspective of the human being, which in section 3 has been implicitly discovered as the actual material subject of those determinations formally carried by the product of labour. In doing so, the dialectical presentation will shed new light on that very content itself. By way of a momentary analytic 'detour' from the synthetic movement of the presentation, which penetrates further into the inner determinations of the fetishistic appearance of the commodity as an autonomous subject with the social power to establish the exchange-relation, the value-form is revealed as the inverted representation, in the consciousness of the human being, of the social character of her own activity. In other words, the commodity proves to be the alienated mode of existence of the private producer's consciousness of the immanent unity of social labour of which her own activity is but an organic moment. It is the transposed form in which the producers consciously experience the indirect nature of their general social relation in this mode of production, projecting it as a social power external to their own individuality.

> The mysterious character of the commodity-form consists therefore simply in the fact that the commodity reflects the social characteristics of men's own labour as objective characteristics of the products of labour themselves, as the socio-natural properties of these things. Hence it also reflects the social relation of the producers to the sum total of labour as a social relation between objects, a relation which exists apart from and outside the producers. Through this substitution, the products of labour become commodities, sensuous things which are at the same time suprasensible or social … [The value-relation] is nothing but the definite social relation between men themselves which assumes here, for them, the fantastic form of a relation between things.[40]

---

[39] Marx 1976c, p. 164.

[40] Marx 1976c, pp. 164–5.

Now, before proceeding with this reconstruction of Marx's further unfolding of the determinations of the alienated consciousness of the commodity producer, it is worth probing deeper into some methodological aspects of the way in which his exposition approaches the determinations discussed just above. As we will see, the peculiar structure that he gives to the presentation disrupts the fluidity of the pure synthetic ideal reproduction of the commodity-form. This has several consequences that could result in a misunderstanding of the systematic sequence of form-determinations by inattentive (or rather, uncritical) readers. On the one hand, and more generally, it could give the impression that the section on commodity fetishism actually has no determinate *systematic* place and significance whatsoever, simply being a 'sociological' analysis which constitutes the basis of Marx's 'theoretical political economy',[41] or a 'philosophical' excursus which strays away from the exposition of the unfolding of the 'economic' determinations of the value-form.[42] On the other hand, we will see that this presentation inevitably leads to repetitions of points already made earlier on in Chapter 1, which can generate the appearance of an inverted order of presentation of certain determinations. Thus, Marx interjects as part of the development of the alienated consciousness as such *repetitions* of arguments he had already developed when he was effectively presenting the determinations of the commodity as the general social relation (the objectified social being, so to speak). That many of those passages just reinstate points already made earlier is evidenced by the way in which Marx introduces them:

> *As the foregoing analysis has already demonstrated*, this fetishism of the world of commodities arises from the peculiar social character of the labour which produces them.[43]

A further point to note in this regard is that one of the particular features of Marx's presentation in the section on commodity fetishism is that, unlike the analytic passage from the form of value to its substance between sections 1 and 2,[44] or the synthetic return to the unity of that substance with its form of existence in section 3,[45] he does not *explicitly inform* the reader about the content of the presentational movement that he is undertaking (e.g. the passage from value and its monetary mode of existence to the consciousness of the commodity producer), or about the formal necessity of that step in the dialectical sequence of form-determinations. However, this does not mean that there is no immanent necessity structuring the flow of the argument, as implied by Reichelt's claim that Marx tended to 'conceal' the dialectical method in the published versions of the critique of political economy (and especially in the second edition of *Capital*) in order to popularise the exposition.[46] As Iñigo Carrera points out,[47] what Marx removed from the exposition, in contrast to that of earlier manuscripts like the *Grundrisse*, are the explicit reflections on the direction that his ideal reproduction of the immanent unity of content and form of a determination should take. In fact, Iñigo Carrera continues,[48] those remarks are, strictly speaking, external to the ideal reproduction of the inner determinations of the object of cognition, which is what the dialectical method is all about. In this sense, the exposition in the published versions of the critique of political economy could be said to be actually *improved* from the point of view of the dialectical method, since it focuses more 'purely' on the 'immanent life of the subject matter' without any alien additions. It is down to the critical reader to recognise and make explicit those formal-methodological aspects which are only implicit in Marx's presentation. By contrast, this could, of course, lead other 'inattentive' readers to think that the section on commodity fetishism has no systematic place in the dialectical presentation, however fundamental it may be in other respects.

---

[41] Rubin 1972.

[44] Marx 1976c, p. 128.

[45] Marx 1976c, p. 139.

Another related issue concerns the point made above about the 'disruption' of the fluidity of the systematic ordering of form-determinations, partly entailed by Marx's idiosyncratic exposition in the first chapter of *Capital*, but partly a reflection of the nature of the subject matter under consideration itself. In effect, one of the peculiar features of Marx's exposition of the determinations of the commodity-form in sections 1 to 3 is that when analytically moving to the more detailed discussion of 'labour' as the human action that posits the value-form (more specifically in section 2), he treats it, as it were, in a purely 'objective' fashion, simply as the source or substance of value, i.e. as the content of the attribute of general exchangeability of commodities. The consequence of this is that nothing is said at that stage about what labour generically is, namely, the specifically human form of the life process and, in that determination, the *conscious* action of the working subject. In Marx's exposition, the explicit positing of this generic determination of labour as conscious metabolic interaction with 'external' nature occurs only in Chapter 7 on 'The Labour Process and the Valorisation Process'.[49] However, even there he develops the generic determination of consciousness as the form of organisation of human productive action rather one-sidedly, that is, only in relation to an abstractly-presented individual character of labour without regard to its immanent social determinations.[50]

---

[46] Reichelt 1995, 2005 and 2007.

[47] Iñigo Carrera 2013, p. 65.

[48] Iñigo Carrera 2013, pp. 65–6.

Be that as it may, the important point for the purpose of my argument here is that in the first three sections of Chapter 1, labour as subjective activity (hence consciousness) is entirely omitted from Marx's presentation. Although no more than an 'informed guess', a plausible explanation for this is that Marx wanted to stress the *real automatism* characterising commodity production as the general social relation. For this reason, he structured his exposition purely around the movement of the commodity, that is, around the simplest form of the labour *product* and the explanation of its power of exchangeability as its historically-specific objective attribute (the value-form). Thus, instead of directly starting with 'individuals producing in society' as he had earlier announced in the Introduction to the *Grundrisse*,[51] in *Capital* Marx took as his point of departure the *thing* that appears as the immediate carrier of that power to establish the unity of the general social relation when the human individual does not consciously organise the latter as her personal attribute.[52] What follows from that starting point is the ideal reproduction of the autonomised self-movement of those form-determinations, and only as a *result* of this exposition, culminating with the money-form as the thing-like immediate mode of existence of the social character of labour in capitalism, does Marx make clear that at stake here is the form in which 'individuals produce in society'. But *in the course* of the dialectical unfolding of the commodity, its producer (and hence her consciousness) is virtually absent. The consequence of this is that when Marx does eventually address the consciousness of the commodity producer as the immediate object of his exposition in section 4, the transition might appear as an abrupt (if not extrinsic) leap. However, my claim is that it immanently follows from the determinations discovered in section 3.[53]

---

[49] Here I would like to argue that there is an element of flexibility in the dialectical presentation. Although overall form-determinations tend to follow a 'strict' systematic sequence, there are certain aspects of the object of cognition which, in principle, could be addressed at different points of the presentation. In those cases, it is down to the researcher to judge where a particular determination fits better. An example of this is Marx's postponement of the treatment of the transfer of the value of the means of production until Chapter 8. Although there is no strict systematic necessity not to address the different roles of past and new labour in the process of value-formation at the level of the commodity-form (since all the determinations presupposed by that qualitative difference have been unfolded at that stage), there are formal reasons that make it more sensible to leave it until later on in the dialectical presentation. Arguably, the distinction acquires full significance in relation to the determination of the diverse elements of the labour process as modes of existence of the production of *surplus value*. Dead labour now becomes a necessary form that capital must assume in order to absorb the only direct source of its valorisation (living labour), but in which its generic determination as a self-expanding magnitude is immediately negated. It becomes posited as *constant* capital in opposition to the only part that does attain self-valorisation, i.e. *variable* capital. From the perspective of the simple production of commodities, the explicit differentiation between the modalities in which the diverse functional elements of the labour process enter into the formation of value of the final product is less relevant. What fundamentally matters for the simple commodity producer is that her commodity's value is realised in full in order to be able to buy all the other use-values she needs for the production of her life. The division of the total socially-necessary labour into past and fresh new living labour expended is not of the essence.

[50] Fitzsimons 2012, pp. 43–4.

Now, regardless of Marx's 'extreme' presentational strategy of obliteration of all reference to human subjectivity in the first three sections of Chapter 1, the very 'inner life' of the subject matter precludes an earlier introduction of a fuller discussion of the form-determinations of the consciousness of the commodity producer as immediate object of exposition.[54] In effect, insofar as the commodity *really is* the form taken by the general social relation in capitalist society, its content in the general social character of labour could hardly be posited until presenting its 'roundabout' manifestation through the expression of value in section 3, that is, in indissoluble unity with its necessary reified mode of social mediation. Seen from a different angle, when Marx's exposition eventually addresses (commodity-producing) labour as such in section 2, it is quite simply impossible to immanently discover the unity of the general social relation since, precisely by virtue of the private character of productive activity in this society, that general social character of production is not directly manifest as an attribute of labour in action. *A fortiori*, it is not possible at that stage to expound in and of itself the form in which commodity producers carry that social character of their individual productive activity as a form-determination of their consciousness. Although the ‘socially necessary’ aspect of value-producing labour discovered through *analysis* already makes evident that the product must be useful for an individual other than its producer (it must be a ‘social use-value’), this social character is still not posited (and hence fully discovered) as entailing the *general unity* of the process of human metabolism as a whole. True, Marx does discover in section 2 that the existence of the commodity he is analysing presupposes a *generalised* social division of labour (yet the latter is not the ‘consequence of propensity to truck, barter and exchange’, as Adam Smith argued in Chapter 2 of *The Wealth of Nations*). However, this analytical discovery is reached by *representational* means when facing the concrete character of labour;[55] more concretely, by the external observation that

---

[51] Marx 1993, p. 83.

[52] Iñigo Carrera 2013, p. 68.

[53] It is interesting that in the appendix to the first edition of *Capital* Marx introduced the discussion of commodity fetishism as the fourth peculiarity of the equivalent form (Marx 1976b, p. 59). The point about the place of commodity fetishism in the appendix to the first edition has also been noted in passing by Chris Arthur (Arthur 2004).

[54] This is valid, of course, if one wants firmly and strictly to remain true to the ideal reproduction of the object. However, the dialectical researcher could decide, for didactic and pedagogic reasons, to introduce remarks which are external to the real movement at stake, but which might help readers who will most likely be used to representational thought but unfamiliar with the form of motion of the dialectical method. In other words, there is a trade-off between rigour and 'reader friendliness' in a context where dialectical cognition is not yet the general form of scientific thought.

> the totality of heterogeneous use-values or physical commodities reflects a totality of similarly heterogeneous forms of useful labour, which differ in order; genus, species and variety: in short, a social division of labour.[56]

In other words, Marx simply points to the seemingly unconnected collection of different concrete labours which comprise social production. In turn, the specificity of the contemporary form of social mediation of the division of labour is discovered by an equally extrinsic comparison of commodity-producing society with pre-capitalist forms of social life, showing that the division of labour is ‘common’ to both and hence a generic determination that does not explain the historicity of value-production. At most, then, the initial analytical encounter with ‘labour’, resulting from the search for the substance of value, could present the determination of consciousness as the human form of organising the one-sidedly individual character of productive activity. This would then reveal that, in the organisation of her privately undertaken process of production, the consciousness and will of the commodity producer is not directly subordinated to any other consciousness and will that could tell her how to allocate her labour-power in a determinate concrete form. In other words, the productive consciousness of the commodity producer would be grasped as being in full control over the *individual* character of labour. However, nothing could be said at that stage of the presentation about the way in which that productive consciousness mediates the organisation of the insertion of that singular productive action into the system of the social division of labour, i.e. about the social character of individual labour.[57]

---

[55] Iñigo Carrera 2007, p. 229.

[56] Marx 1976c, p. 132.

In sum, an exposition that rigorously sticks to the ideal reproduction of the object can address the form-determinations of the consciousness of the commodity producer only after facing the unity of the general social relation. The latter can be firstly discovered only as 'spoken in the language of commodities' (i.e. through the expression of the value-content in the form of exchange-value) and not directly as a personal determination of the human individual. However, once that point in the dialectical exposition of the commodity has been reached (now *known*, in its money-form, as the immediate carrier of the unity of the general social relation of production), its own immanent development demands that the presentation veers toward the explicit scrutiny of the consciousness of the producer as its immediate subject matter.

Now, in this passage, the exposition will inevitably have to retrace some of its steps and reconsider 'commodity-producing labour'. However, in this new take on its determinations, labour can be immediately grasped in the unity of its individual and general social character *and* 'spoken in the language of human beings', that is, as their *conscious* socially-determined individual life activity. It is this reconsideration of labour as human action which, as anticipated above, allows the exposition to throw new light on the *content* of the value-form. For, as we have seen, the latter is thus revealed not simply as the thing-like representation of the social character of privately undertaken labour. Additionally, it can now be recognised as a form of objectivity which is unconsciously projected by human consciousness itself when regulating such a privately-performed productive action.

> *The private producer's brain reflects this twofold social character of his labour only in the forms which appear in practical intercourse, in the*

---

[57] An earlier introduction of the subjectivity of the commodity producer along the lines suggested above can be found in Iñigo Carrera's alternative exposition of the commodity. See Iñigo Carrera 2007, pp. 33–4. The advantage of this presentational strategy is that it allows a smoother transition between the form of value and commodity fetishism, since by the beginning of section 4 consciousness is already there confronting its own social determinations in the autonomous shapes of the commodity and money-forms. The downside is that it 'spoils' the strategy of making the presentation reflect more starkly the objective automatism of the organisation of the process of social metabolism through the commodity-form.

> *exchange of products.* Hence the socially useful character of his private labour is reflected in the form that the product of labour has to be useful to others, and the social character of the equality of the various kinds of labour is reflected in the form of the common character, as values, possessed by these materially different things, the products of labour.[58]

This determination of the objectivity of value as an alienated external form posited by the productive consciousness of the private individual is explicitly and unequivocally presented by Marx in a passage from the first edition of *Capital.*

> So just *what* a value is does not stand written on its forehead. In order to relate their products to one another as commodities, men are compelled to equate their various labours to abstract human labour. They do not know it, but they *do* it, by reducing the material thing to the abstraction, *value*. This is a primordial and hence unconsciously instinctive operation of their brain, which necessarily grows out of the particular manner of their material production and the relationships into which this production sets them.[59]

In a nutshell, value becomes known as the mode of existence of the alienated consciousness of the private producer, a 'socially valid', therefore objective, form of thought.[60]

Note, however, that from the point of view of the formal structure of presentation, this reconsideration of the content of value, even if necessary, entails an instance of diversion from the synthetic progress of dialectical development. It is the 'analytic detour' in Marx's presentation to which I referred above, and that takes the reader from value/money back to privately-organised social labour (now explicitly posited as mediated by consciousness). Once this analytic deepening of the content of value is exhausted, the dialectical presentation must obviously resume the synthetic movement of reproduction from the prior point at which the analysis culminated, namely, the discovery of value as the alienated form in which the consciousness of the private producer organises her individual participation in the process of social metabolism in its unity.

---

[58] Marx 1976c, p. 166; emphasis added.

[59] Marx 1976b, p. 36.

[60] Marx 1976c, p. 169. On the connection between commodity-form and consciousness, see the detailed discussion in Fitzsimons 2012. Reichelt 2007 also provides insightful reflections on value objectivity as 'unconsciously posited by an act of consciousness'.

But this obviously implies an unavoidable element of repetition of the passage over the synthetic sequence from 'private labour' to 'value'. It is precisely those passages from Marx's discussion of commodity fetishism which could lead to the (misguided) reading that the essential content of the section revolves around the explanation of why private labour must take the value-form of its product.[61] In order to clarify this point, let us return to the more detailed reconstruction of Marx's systematic argument in the fourth section of Chapter 1.

The Determinations of the Alienated Form Taken by the Productive Consciousness of the Private Individual

My methodologically-minded reading of the section on commodity fetishism has so far reached the point at which Marx's exposition analytically discovers the alienated consciousness of the (private) producer behind the commodity-form of the product of labour. The limits of this analytic discovery of the alienated consciousness for the further progress of the dialectical investigation are formally analogous to those experienced by the search for the content of the exchangeability of the commodity in sections 1 and 2 of Chapter 1 of *Capital*. As a reflection of the general role of the phase of analysis in the dialectical method discussed in the previous section, it can only account for the 'what' of the phenomenon under scrutiny, but is incapable of offering an explanation of its determinate ‘why’. Specifically, the analysis of the commodity-form from the perspective of the human being as the material subject of social labour can shed light on what the fetish-like character of the product is: the inverted representation of the social determinations of individual labour in the form of value. But this leaves the question as to why the consciousness of the human being must experience her own immanent determinations in such an alienated form. As follows from Marx's materialist standpoint, this fetishised form of consciousness can have no other basis than the historical form taken by social being in capitalism, that is, the ‘specific social character of the labour which produces’ commodities, namely, private labour: ‘Objects of utility become commodities only because they are the products of the labour of private individuals who work independently of each other’.[62]

---

[61] An emblematic *locus classicus* of this misreading can be found in the influential work of Rubin, for whom the account of commodity fetishism constitutes the 'propaedeutic' to, and basis of, the determinations of the value-form (Rubin 1972, pp. 6, 61). In effect, Rubin considers that section 3 of the first chapter contains a *purely formal* development that simply illustrates the different forms of exchange-value as modes of expression of value, and further submits that 'Marx does not remain on the explanation of the form of value, and quickly passes to its various modifications, to the individual "forms of value": accidental, expanded, general and monetary' (Rubin 1972, p. 114). Thus, the precise place where Marx unfolds in great detail the explanation of the reason to be of value is taken by Rubin as containing no more than merely 'incidental' brief passages on value as social form (ibid.). And where exactly does Rubin find a 'detailed elaboration' of the value form? For instance, in a footnote, specifically number 34 in the Penguin edition of *Capital* (Marx 1976c, p. 169). Now, by definition, a footnote can hardly contain the elaboration of the essential content of a form-determination. Furthermore, in that particular footnote, Marx is unambiguously commenting on the ideological and apologetic character of the science of political economy (for falling prey to the fetish-like character of the commodity), and is not, by any stretch of the imagination, 'elaborating in greater detail' on the determinations of the value-form.

The explanation of the necessity of the alienated consciousness of the commodity producer must therefore lie in the ideal reproduction of the form in which the social character of private labour asserts itself through the exchange of commodities. Having reached that point, Marx's exposition thus resumes, in the rest of the sixth paragraph of section 4, the synthetic unfolding of the movement of the unity of the general social relation mediated by the commodity-form. However, unlike the earlier account in section 3 on the ‘value-form, or exchange-value’, the dialectical development can now explicitly posit the indirect form in which social labour attains unity from the perspective of the conscious practical activity of private individuals.

> The sum total of the labour of these private individuals forms the aggregate labour of society. Since the producers do not come into social contact until they exchange the products of their labour, the specific social characteristics of their private labours appear only within this exchange. In other words, the labour of the private individual manifests itself as an element of the total labour of society only through the relations which the act of exchange establishes between the products, and, through their mediation, between the producers. To the producers, therefore, the social relations between their private labours appear as what they are, i.e. they do not appear as direct social relations between persons in their work, but rather as material [*dinglich*] relations between persons and social relations between things.[63]

---

[62] Marx 1976c, p. 165.

[63] Marx 1976c, pp. 165–6.

Marx's presentation thus finally unfolds the necessity of the alienated consciousness of the commodity producer. As a private and independent human being, the producer is incapable of recognising that her productive action possesses social determinations that transcend the immediacy of its singularity. Consequently, when organising the expenditure of the labour-power that she embodies, the consciousness of the human individual must project or transpose – hence confront – those individually-borne social powers as external to her individuality and existing as the objective attribute of the product, which allows it to enter the exchange-relation and manifest indirectly the human subject's immanent determination as an individual organ of social labour: the form of exchangeability or the value-form. In sum, the latter is the fetishised form in which the consciousness of the private producer resolves the organisation of her participation in the general process of social metabolism.

With this Marx expounds the determination of consciousness with regards to its most general form in capitalism. From this simplest determination of the consciousness of the commodity producer, he then proceeds to unfold its more concrete form of realisation in its generic condition as the human form of organising transformative action upon nature. In the first place, through the productive action that it privately regulates in the direct process of production. Thus, the producer not only faces her own social powers as external to her subjectivity and as carried by the product of her labour in the process of exchange through which social labour attains unity. As exchange extends its role in social reproduction, the plenitude of which is reached in capitalist society where it becomes the general social relation, this inverted consciousness starts to regulate the direct production-process itself. Under those circumstances, already at that moment must the commodity producer put her consciousness at the service of social powers which she sees as alien to her subjectivity, that is, as belonging to the commodity.[64] When resolving the concrete form in which she will privately expend the aliquot part of the total labour-power of society that she embodies, the social character of her labour already appears to the consciousness of the producer as an attribute of the product in a twofold sense.[65] Firstly, she must produce a use-value which must satisfy the needs of other individuals with whom she does not have any immediate or direct social nexus. Secondly, that socially useful character of the product must be formally mediated by its determination as the bearer of the property to be transformed into any other use-value, that is, the attribute of general exchangeability or the value-form. Thus, at the very moment in which she actually exerts her productive subjectivity in the direct process of production, and in order to organise her affirmation as an individual organ of the social division of labour, the private individual must produce not only socially useful things, but also exchangeable products; she must posit value. In brief, the private individual must already alienate her productive consciousness in the commodity when acting in the immediate production process.[66]

---

[64] Iñigo Carrera 2007, pp. 58–9.

[65] Marx 1976c, p. 166.

At this juncture, after having uncovered value as the reified mode of existence of the determinations of consciousness, Marx hastens to clarify that this by no means implies that the human individual is actually aware of this fact. Thus, he argues, it is not the case that commodity producers consciously recognise the determination of their private labours as individual fragments of human social labour and thereby exchange their products as equivalent materialisations of abstract labour, i.e. give them the form of value. It is the other way around. They *unconsciously* give the products of labour the form of value and, through this reified social mediation, they equalise behind their own backs their private labours as individual organs of the total labour of society on the basis of their material identity as pure expenditures of human labour-power.[67] The constitution of the social objectivity of the value-form, whilst being the spontaneous product of their own brain (hence of their consciousness), appears to the commodity producers as a *fait accompli* springing by nature from the materiality of the product of labour. In sum, the consciousness of the commodity producer, in its most general and simple form, is not only an inverted consciousness, but also an apparent one. As the bearer of that form of consciousness, the human individual is unable to recognise the necessity – i.e. the determinations – of her conscious action beyond the appearance of being an abstractly independent action. As the necessary 'spontaneous and natural' form in which the producer privately organises the insertion of her practical action into the social metabolic process as a whole, this immediate practical consciousness persists even after political economy scientifically discovers the labour content of the value-form.[68]

---

[66] In this sense, value-positing is for Marx an immanent result of the direct production process and not, as Rubin and contemporary 'circulationist' value-form theorists argue, a determination of the sphere of circulation which 'leaves its imprint' on a labour process that posits value only 'mentally' or 'latently' (Rubin 1972; Reuten and Williams 1989; Heinrich 2011 and 2012). For a more detailed critique of Rubin's circulationist value-form theory and its political implications, see Kicillof and Starosta 2007a. Bonefeld 2010, drawing on Bellofiore 2009 and Arthur 2001, attempts to avoid the pitfalls of Rubin's circulationist views by giving an objective character (as opposed to merely mental or ideal) to the projection of the ghost-like objectivity of value back into production from its original constitution in exchange. For a critique of Bonefeld's position, see Kicillof and Starosta 2011.

[67] Marx 1976c, pp. 166–7.

In this sense, the corollary of Marx's discussion of commodity fetishism is that consciousness is actually torn asunder when social being takes the form of private labour. It simultaneously exists both as a form of the subject of social labour and as an objective form of its product.[69] Before continuing with the textual commentary on commodity fetishism, let us probe deeper into this fundamental point.

In its generic condition as the specifically human capacity to organise the life-process, consciousness always entails a twofold determination as much as the labouring activity that it regulates.[70] On the one hand, it is the form in which the human being rules the immediacy of the individual productive expenditure of her corporeal powers in order to appropriate and transform external nature into a means for human life. In this determination, consciousness is the human capacity to organise the unfolding of the individual character of labour. On the other hand, those individually-borne productive powers can only be constituted socially, that is, they can only develop as a result of the productive action of other individuals (who, for instance, have participated in the production of the use-values whose consumption resulted in the productive attributes borne by the former individual's labour-power). Moreover, the individual labourer produces use-values not solely for her own consumption, but for others, that is, *social* use-values. Although an individual human action, labour therefore always has an intrinsically social character as well. This twofold character is borne by consciousness as its necessary form of organisation. Consciousness thereby does not simply undertake the regulation of the individual appropriation of the potentialities of external nature in order to transform it, but must also mediate the establishment of individual labour's immanent unity with the socially-general metabolic process of which it is an organic part. As an attribute borne by the individuality of each human being, consciousness is thus the capacity to establish the unity of social labour through the individual productive action of each of its subjects, i.e. to regulate the social character of individual labour.

It is this twofold immanent potentiality of consciousness which is torn apart in commodity-producing society. Insofar as the private form of labour negates the capacity of human subjectivity to recognise and control the social character of its activity, that material potentiality of consciousness becomes formally alienated in the commodity. In this social determination, consciousness thereby exists in the mode of the objectivity of value. But the other side of this inversion is that, as subjective capacity, the consciousness of the commodity producer becomes determined as an abstractly-individual human attribute. Only in this one-sided form does consciousness immediately exist *as consciousness*.[71]

---

[68] Marx 1976c, p. 167.

[69] Fitzsimons 2012, p. 37.

[70] Fitzsimons 2012, pp. 44–6, Iñigo Carrera 2007, pp. 43–9.

Based on these premises, let us now return to Marx's argument in the section on commodity fetishism. After having established the *genesis* or *social constitution* of the doubling of the consciousness of the commodity producer, Marx systematically proceeds to unfold the concrete form in which this abstractly-individual practical subjectivity apprehends the alienated mode of existence of its social determinations as an *already-constituted objective form*. More specifically, the immediate practical consciousness of the commodity producer ideally represents the movement of her alienated social being in the form of an estimate of the proportions in which her commodities will exchange for the other commodities she needs. Thus, Marx comments:

> What initially concerns producers in practice when they make an exchange is how much of some other product they get for their own; in what proportions can the products be exchanged?[72]

---

[71] Now, lest my argument be misread as 'idealist', it goes without saying that I am not referring to an abstractly autonomous consciousness floating in mid-air but to the conscious social being of the human individual as a productive subject, i.e. to its determination as an organ of the materiality of the social metabolic process of humanity. More specifically, I am referring to the way in which the private form taken by the organisation of social labour is necessarily mediated by – or exists in and through – the conscious productive practice of human beings. In other words, there are no social relations of production or social practice whose inner determinations could exist abstractly separated from (i.e. not *immanently* mediated by) consciousness. Social practice is always *conscious* practical activity. The point of Marx's 'materialism' is not to conceive of social being as a self-subsistent existence that externally 'causes' or 'conditions' from such exteriority an equally self-subsisting consciousness. Such severance and consequent external relation of social being and consciousness would certainly be idealist. As follows from Marx's materialist dialectical method, social relations of production are the immanent material *content* which is necessarily realised in the *form* of the determinations of the consciousness of the human individual. As Marx eloquently puts it in the *1861–63 Manuscripts*, 'social relations only exist between human beings to the extent that they think' (Marx 1988, p. 232).

[72] Marx 1976c, p. 167.

Now, insofar as consciousness is but the organisation of human action, the next systematic step after presenting the *form* in which the private producer represents 'in her head' the value-determinations in a constituted form, must consist in expounding the way in which this practical subjectivity productively *acts* on this basis in order to take part in the system of all-round material interdependence characterising generalised commodity production. When faced with the movement of the unity of their social life-process in a form that escapes their own individual potentialities, human beings are condemned to act, in Reichelt's eloquent formulation, as

> executors of constraints generated and reproduced by themselves, which are implemented in and through their conscious actions without, however, being consciously accessible to them.[73]

At stake here, then, is the *autonomisation* of the general social relation from the conscious control of individuals and the consequent all-too-real appearance or 'objective illusion' of *automatism* characterising capitalistic production.

As Marx argues, this determination of the practical action of private individuals becomes firmly established only when the movement of the quantitative articulation of the social division of labour becomes regulated by the magnitude of value.[74] This is because the degree in which the products of labour are exchangeable starts to vary independently of the producer's individual consciousness and will. Hence, in order to satisfy her qualitatively and quantitatively determined needs – thereby reproducing her natural life – the producer cannot but determine her consciousness and will as the servants of the capricious changes of the magnitude of value of the commodity she produces, which varies 'continually, independently of the will, foreknowledge and actions of the exchangers'.[75] In other words, she not only faces her own social determinations as alien powers borne by the product of labour, but the latter comes to control the producer herself. As Iñigo Carrera succinctly puts it,[76] the commodity producer can reproduce herself as a *person* only by acting as the most abject *personification* of the commodity.[77]

[73] Reichelt 2007, p. 5.

[74] Marx 1976c, p. 167.

[75] Ibid.

[76] Iñigo Carrera 2008, pp. 11–12.

[77] The rest of the section in Chapter 1 of *Capital* deals with the *ideological* scientific form of the alienated consciousness of the modern individual (political economy) and with general comments on other social forms and their respective forms of social consciousness.

With this characterisation of the practical subjectivity of human beings as personifications of the movement of the value-form, Marx’s exposition completes the ideal reproduction of the simplest social determinations of the alienated consciousness of the private individual and its concrete forms in the sphere of production. From the point of view of the formal structure of the dialectical presentation, the important point to bring out is the precise sequence of form-determinations that guides the flow of Marx’s argument, which I will now formally sketch out.

As I have shown in the previous section, Marx’s exposition firstly moves analytically in order to discover the alienated consciousness of the commodity producer behind the value-form and private labour as the foundation of the former. From that point onwards, he undertakes again the synthetic return journey from private labour to value, albeit now as mediated by consciousness, thereby accounting for the ‘why’ of the latter’s alienated mode of existence in the commodity. In this phase of his argument, the unfolding of novel form-determinations concerning the inner connection between consciousness and value inevitably overlaps with repetitions of points made earlier about the inner connection between private labour and value. After moving from human subjectivity to its transposed form of existence in the objectivity of value, Marx turns his attention back to the material subject of social labour in order to uncover the form of this consciousness which, in its immediacy, appears as abstracted from its social determinations. It is here that, strictly speaking, the presentation of entirely new content actually starts to unfold. The exposition thus reveals the sundering of the immanent twofold determination of human productive consciousness (individual and social) into an abstractly individual attribute of the material subject of social labour and the objectified mode of existence of its social determinations in the commodity, the latter being posited by the spontaneous or unconscious act of consciousness itself. What follows is the development of the concrete form in which the private producers ideally reflect on those social determinations, grasping them in their immediacy as already-existing forms of human life. On the basis of these immediate appearances, they organise their alienated practical action in order to reproduce the materiality of their lives, thereby becoming determined as personifications of the autonomised self-movement of those objectified forms of social mediation. Note in this regard that this means that the relation between consciousness and value suffers, as it were, a reversal. If at the beginning value

---

The latter are external observations in the dialectical presentation which evidently play a didactic or pedagogical role by helping to emphasise the specificity of capitalist social forms.

appeared as the self-negating mode of existence of consciousness, the exposition later reveals that human subjectivity and its conscious practical action actually develop into a concrete form of the self-movement of the value-form. One could argue that in this way Marx eventually justifies his presentational strategy of total obliteration of subjectivity when structuring the argument in the first three sections of Chapter 1 in apparently 'objectivistic' terms around the explanation of the exchangeability of the commodity as such: the establishment of the unity of capitalist social production proves to be predicated on a real automatism and not on the conscious knowing and willing of the material subject of social labour.

With all this in mind, we can now take stock of the precise systematic place and significance of the section on commodity fetishism in Marx's order of presentation. Inasmuch as it has the consciousness of the commodity producer as its immediate object of exposition, it can only appear *after* the analytic and synthetic development of the determinations of the value-form. The reason for this is that the determinations unfolded in the former are nothing more than the forms in which the latter concretely develop. To put it plainly, *the individual consciousness of the commodity producer is a concrete form in which the commodity, as the formal subject of the process of human metabolism, realises its own determinations*.

The full significance of this order of determination can be better appreciated in Chapter 2, in which, as anticipated above, Marx presents that alienated consciousness in motion, effectively acting as personification of her commodity in the sphere of exchange, that is, in the phase of the social reproduction process in which the unity of the social character of labour becomes manifest through a direct relation between human beings (i.e. the voluntary contract). In other words, when he presents the process of exchange as the concrete realisation of the social relation materialised in the commodity. After analytically penetrating the immediate appearance that it is the human individual who consciously and voluntarily controls the product of labour, Marx sets out to unfold the realisation of the essential determination with which the previous section finished, namely: in capitalist society,

> the characters who appear on the economic stage are merely personifications of economic relations: it is as the bearers of these economic relations that they come into contact with each other.[78]

What follows, then, is the alienated action of individuals determined as personifications who, through their unconsciously-organised social action, cannot help manifesting by way of their 'natural instinct' the 'natural laws of the commodity' discovered in Chapter 1.[79] In effect, out of the development of the exchange-process necessarily crystallises the money-form of the commodity. The value-form of the product of labour affirms itself as an abstract form through its self-negation, that is, by realising its own necessity in the form of the atomistic action of commodity owners, which act as vehicles for the realisation of the 'will' of their commodities.[80] Hence the importance of grasping not only the unity between the section on commodity fetishism and the rest of Chapter 1, but also of accounting for the crucial presentational unity between the latter as a whole and Chapter 2.

---

[78] Marx 1976c, p. 179.

As the ideal reproduction of these real relations among forms of different levels of abstraction, the dialectical presentation cannot posit the fetishism of commodities – i.e. the inverted self-consciousness of the commodity producer and its determination as personification of the value-form – prior to the unfolding of the social relations whose unity is ideally mediated in that historical form of consciousness. If it did so, it would, like it or not, fall prey to the idealist inversion of positing consciousness as taking concrete form in social being. And, since the times of *The German Ideology*, Marx and Engels had made it clear that such a way of conceiving the relation between social being and forms of consciousness entailed turning the real relations upside down. Maybe aware of the risk that his own exposition might be read in that inverted fashion, Marx in the first edition of *Capital* explicitly stated the order of the relation.

> First their relationship exists in a practical mode. Second, however, their relationship exists as relationship for them. The way in which it exists for them or is reflected in their brain arises from the very nature of the relationship.[81]

Conclusion

By way of brief concluding remarks, let us point to some implications of overlooking the precise systematic meaning and place of commodity fetishism in Marx's dialectical exposition in *Capital* as reconstructed above. In a nutshell,

---

[79] Marx 1976c, p. 180.

[80] Arthur 2004, pp. 37–8, correctly points this out. Heinrich also brings out this issue in distinguishing between Marx's exposition of the 'economic determinate form' and the 'activity of commodity owners'. See Heinrich 2012, pp. 72–9.

[81] Marx 1976b, p. 36.

I think that it leads to a conception of Marx's critique of political economy, and in particular of the section on commodity fetishism, one-sidedly determined as an exposition of the social constitution of the forms of objectivity of capitalist society. The transposed relation between human practical activity and its objectified forms of social mediation becomes thus exhausted in the constitution of those forms of objectivity as a hostile alienated social power standing above and constraining the affirmation of an abstractly-free human individuality. But this inversion is not followed through to its necessary unfolding in the determination of the latter as the pure personification of the value-form. This has the consequence of rendering the most general determination of human individuality in capitalism undertheorised, thus opening up the possibility of postulating an instance of exteriority between human consciousness and will (i.e. subjectivity) and the value-form; the former is thereby seen as not fully determined as a mode of existence of the latter. As I have argued at great length elsewhere,[82] this exteriority eventually hinders the full comprehension of what a consequent dialectical development of these abstract determinations necessarily leads to, namely: the discovery of the determination of (social) capital as the concrete alienated subject of the historical movement of present-day society. To put it differently, this reading fails to follow the transition from the fetishism of commodities to the fetishism of capital, that is, from its abstract determination as a formal inversion between subject and product of social labour up to its full transformation into a complete real inversion, i.e. to the constitution of the total social capital as the alienated subject of the movement of modern society, with social classes as its antagonistic collective personifications. It goes without saying that this does not entail an abstractly theoretical interest. Quite to the contrary, it can be shown that it is a necessary step to discovering the determinations of the revolutionary subjectivity of the working class as *immanent* in the very unfolding of the reified forms of social mediation of capitalist society. In other words, a proper grasp of the systematic content and significance of commodity fetishism is a condition for the development of dialectical science into the conscious practical critique of the capital-form.

Fetishism and Revolution in the Critique of Political Economy: Critical Reflections on some Contemporary Readings of Marx's *Capital*

Guido Starosta

Abstract

The aim of this article is to examine a series of recent contributions to the reading of Marx's *Capital* that stress its specific determination as a dialectical investigation of objectified or fetishised forms of social mediation in capitalist society: on the one hand, the so-called *Neue Marx-Lektüre* originated in Germany towards the end of the 1960s and, on the other, the more widely circulated work of authors associated with so-called *Open Marxism*. The interesting aspect of these works is that they draw the implications of Marx's critique of political economy not only for the comprehension of the fetishised forms of social *objectivity* in capitalism, but also for the comprehension of the forms of *subjectivity* of the modern individual. More specifically, all these contributions broadly share the insightful view that the content of the simplest determination of human individuality in the capitalist mode of production is its alienated existence as 'personification of economic categories'. However, this article argues that the limits of these perspectives become apparent when it comes to uncovering the grounds of the revolutionary form of subjectivity which carries the potentiality to transcend capitalist alienation. For these perspectives fail to ground the revolutionary form of subjectivity in the immanent unfolding of capitalist forms of social mediation. In the case of the *Neue Marx-Lektüre*, it quite simply leaves the *problematique* of the revolutionary subject outside the scope of the critique of political economy. In the case of *Open Marxism*, despite-valiant attempts at overcoming all exteriority in their conceptualisation of the relationship between human subjectivity and capital, they end up grounding the revolutionary transformative powers of the working class outside the latter's alienated existence as personification of economic categories; more specifically, in an abstract humanity lacking in social determinations. In contrast to these perspectives, this paper develops an alternative approach to the Marxian critique of political economy which provides an account of the revolutionary potentialities of the working class as immanent in its full determination as an attribute of the alienated or fetishised movement of the capital-form.

Key Words: **_Capital_, Fetishism, Revolution, Dialectics; _Neue Marx-Lektüre_, Open _Marxism_**

Introduction

The aim of this article is to examine a series of recent contributions to the reading of Marx's *Capital* that stress its specific determination as a dialectical investigation of objectified or fetishised forms of social mediation in capitalist society. In the first place, I critically engage with the contribution by authors associated with the so-called *Neue Marx-Lektüre* originated in Germany towards the end of the 1960s (Backhaus 1980, 1992, 2005; Reichelt 1982, 1995, 2005, 2007; Heinrich 2009; Fineschi 2009). Secondly, I also scrutinize the more widely circulated work of authors associated with so-called *Open Marxism* (Bonefeld y Holloway 1991; Bonefeld, Gunn y Psychopedis 1992a, 1992b; Bonefeld, Holloway y Psychopedis 1995; Bonefeld y Psychopedis 2005). In this latter case, I shall particularly focus on Werner Bonefeld's contribution (1992, 1993, 1995, 2014), who explicitly draws intellectual inspiration from Backhaus's and Reichelt's ideas (Bonefeld 1998, 2001, 2014), albeit within a framework which is more overtly *political*.[1] Furthermore, I shall discuss Richard Gunn's more 'philosophically-minded' take on *Open Marxist* themes, which probably constitutes the more sophisticated and rigorous contribution to the methodological dimension of this approach (Gunn 1987, 1989, 1992).

In my view, perhaps the most interesting aspect of all these works is that they draw the implications of Marx's critique of political economy not only for the comprehension of the fetishised forms of social *objectivity* in capitalism, but also for the comprehension of the forms of *subjectivity* of the modern individual. In effect, all these contributions broadly share the view, correct as I see it, that the content of the simplest determination of human individuality in the capitalist mode of production is its alienated existence as personification of 'economic categories'. However, I shall show below that the limits of these perspectives become apparent when it comes to uncovering the grounds of the form of subjectivity which carries the immanent potentiality to transcend capitalist alienation, that is, when it comes to bring to light the determinations of the revolutionary subject.

In order to substantiate this argument, this article starts out by offering an in depth and detailed critical discussion of the *Neue Marx-Lektüre* and the *Open Marxist* approach, arguing that these authors fail to ground the emergence of revolutionary subjectivity in the immanent unfolding of capitalist forms of social mediation. In the former case, quite simply by leaving the *problematique* of the revolutionary subject outside the scope of the critique of political economy. In the case of *Open Marxism*, despite its valiant attempts at overcoming all exteriority in their conceptualisation of the relationship between human subjectivity and capital, they end up grounding the revolutionary transformative powers of the working class outside the latter's alienated existence as 'personification of economic categories'; more specifically, they end up grounding it in an abstract humanity lacking in social determinations.

Furthermore, the article develops this critical discussion along *methodological* lines demonstrating that the substantive weaknesses of both the *Neue Marx-Lektüre* and *Open Marxism* go hand in hand with an inadequate conception of the scientific-critical method needed immanently to discover the determinations of revolutionary subjectivity. More concretely, for these authors the Marxian scientific-critical method underlying the discovery of revolutionary praxis simply boils down to the analytic movement entailed by the '*reductio ad hominem*', through which the dialectical investigation traces the human origin of economic categories. The 'genetic' or 'synthetic' aspect of dialectics is thus relegated to the role of explaining the social constitution of the forms of objectivity of capitalist society and, at most, of the forms of subjectivity that bear their *reproduction*. However, according to this conception, this second moment of the dialectical investigation has no role to play with regards to the comprehension of the foundations of revolutionary subjectivity.

In contrast to these perspectives, I develop an alternative approach inspired by the contribution to the critique of political economy of the Argentine scholar Juan Iñigo Carrera (1992, 2007, 2013) which, insofar as it attempts to provide an account of the revolutionary potentialities of the working class as immanent in its full determination as 'personification' of the movement of capital, differs from the two readings just outlined on the following two key methodological dimensions. In the first place, it is argued that insofar as revolutionary subjectivity is a 'unity of many determinations', its ground cannot be found at the 'level of abstraction' of commodity fetishism, as implicitly follows from the *Neue Marx-Lektüre* and the *Open Marxist* approach. In the second place, and as a consequence, it is shown that the critical moment of the Marxian dialectical method does not simply consist of the *reductio ad hominem*. The latter undoubtedly is the essentially analytic and Feuerbach-inspired approach deployed by Marx in early texts such as the *1844 Paris Manuscripts*. However, I maintain that Marx overcame the limits of the latter methodological perspective in the 'mature' versions of his critique of political economy (the *Grundrisse*, the *1859 Contribution* and, especially, *Capital*). In effect, in these latter works the discovery of revolutionary subjectivity immanently emerges out of the *synthetic unfolding* of the *totality* of form determinations of capital as the alienated concrete subject of the movement of modern society, with the commodity form as its necessary yet only *simplest* expression (and hence as the point of departure of the dialectical presentation which *culminates* with revolutionary subjectivity).

Method and practical critique from the *Neue Marx-Lektüre* to *Open Marxism*

Backhaus's and Reichelt's Neue Marx-Lektüre

We pointed out above that both the *Neue Marx-Lektüre* and its more politicised reception by *Open Marxism* in the Anglophone world share a particular conception of the method and significance of the Marxian critique of the fetishised forms of capitalist social mediation. In effect, in their reducing the critical moment of the investigation of commodity fetishism to the mere discovery of the human content behind the alienated objectivity of economic categories, it can be argued that these authors develop what I have elsewhere termed a 'Feuerbachian' reading of this aspect of Marx's method in his 'mature' works (Starosta 2015). In other words, what eventuates is a variation of what Avineri referred to in his classic book as the method of *transformative criticism* that the young Marx had taken over from the author of *The Essence of Christianity* (Avineri 1993). In this sense, it would seem that there would be no essential methodological difference between the critical method of *Capital* and that which structures Marx's first attempt at the critique of political economy in the *1844 Paris Manuscripts*. The only difference would be that in Marx's later texts, he not only reduces alienated social forms to its human content but also answers (or does so more fully) the question as to why that content takes on such a fetishised form.

But 'if the point is to change the world', then the subsequent problem is how to turn the insight in the human basis of the alienated objectivity of economic categories into *practical critique*, that is, how to convert it into emancipating conscious practice. And it is here where, eventually, the recourse to a moment of exteriority to capitalist social relations tends to creep in as the source of the transformative powers of revolutionary action. Broadly put, for such Marxists the transformative powers of our action are located not in commodity-determined practice itself, but in the essential character of an abstract material content deprived of social determinations which is deemed 'logically' prior to its perverted social form as value-producing, albeit only appearing and existing immanently in and through it. For those readings, this mere discovery of the human content of 'economic categories' exhausts the thinking needed consciously to organise the practical critique of capitalism. Let us examine this matter more closely through a discussion of some of these contributions.

Perhaps a good place to start is the work of Hans-Georg Backhaus, who explicitly traces the Feuerbachian lineage of Marx's method of critique. According to Backhaus, from an initial application 'in his critique of the metaphysical theory of the state', Marx expanded the scope of this method to economic objects as material forms of self-estrangement, commensurable to its metaphysical and theological forms (Backhaus 2005, pp. 18–19). This 'critical genetic method' is said to have two main aspects – the critical and the anthropological. The former does not simply consist in describing and denouncing the existing contradictions between dogmas and institutions, but centrally aims at explicating the inner genesis or necessity of those contradictions (Backhaus 2005, p. 19). In turn, the anthropological aspect of the method involves an *ad hominem* reduction, the demonstration of the human basis of the economic object as a material form of self-estrangement, which is thus rendered in its totality as an object of critique (ibid.). The critique of economic categories thus entails the transcendence of the economic standpoint (Backhaus 2005, p. 23).

In Backhaus's reading, this 'application' of the 'critical genetic method' to the discipline of economics is employed by Marx not only in his early writings (an indisputable fact as I see it), but also in his mature critique of political economy (Backhaus 2005, pp. 21ss). The main thrust of the critique remains the same: whilst economics:

> accept[s] economic forms and categories without thought, that is in an unreflective manner … Marx, in contrast, seeks to 'derive' these forms and categories as inverted forms of social relations (Backhaus 2005, p. 21).

The 'dialectical method of exposition' is thus essentially seen as the genetic development of those alienated forms of *objectivity* out of human sensuous practice. (Backhaus 2005, p. 22). The general method of critique does not change in this reading, only its terminology (Backhaus 2005, p. 25). In the words of Backhaus himself:

> In variation of this thought process, Marx argues in the mature *Critique* of 1859 that what the economists 'have just ponderously described as a thing reappears as a social relation and, a moment later, having been defined as a social relation, teases them once more as a thing' (Marx 1971, p. 35). If one replaces 'social relation' by 'appearance of humanness' and thing qua 'value thing' by the thing in 'difference from humanness' that, as a transcendental thing, is transposed in a sphere 'outside of Man', then the continuity of the fundamental character of Marx's critique of economics from the early writing to *Capital* becomes sufficiently clear (Backhaus 2005, p. 25).

Now, lest my argument be misread, my claim is not that these contributions from the *Neue Lektüre* see no methodological change whatsoever between Marx's early critique of economics and his mature version. My point is that they do not posit any change insofar as the nature of *critique* is concerned: the *reductio ad hominem* is considered to be the continuing ground for revolutionary praxis (Reichelt 2005, p. 38). Yet, this novel reading does develop two additional methodological elements which are relevant for the purpose of the present discussion.

In the first place, these authors argue that in Marx's mature critique, the genetic aspect of his method is not simply predicated on Feuerbach. Insofar as the 'inverted world of capital' (as self-valorising value) resembles Hegel's second supersensible world, 'which in its reality … contains within itself … both the sensuous and the first supersensible world', (Reichelt 2005, p. 32), Marx's mature critique also drew on Hegel's logic for the 'dialectical development of categories' (Reichelt 2005, p. 43). In other words, Hegel's dialectical method provided Marx with the general form of motion of *synthetic* exposition of the necessary sequence of form-determinations understood as 'objective forms of thought' (Reichelt 2005, p. 57).

Secondly, taking cue from Adorno's concept of society as the 'unity of subject and object', (Backhaus 1992, p. 56), which involves 'an ongoing process of inversion of subjectivity and objectivity, and vice versa', (Backhaus 1992, p. 60), both Backhaus and Reichelt posit the alienated determination of human beings as 'personifications of economic categories' or 'character masks', as a central element of Marx's dialectical method in *Capital* (Backhaus 1992, p. 60; Reichelt 1982, p. 168). While this insight could be a promising programmatic starting point for an attempt at a critical investigation of the determinations of revolutionary subjectivity, this is not a path that these German scholars follow. Their discussion unfortunately tends to remain at a very high level of abstraction, dealing with the simpler form determinations of capital. As *Endnotes* 2 write, 'class plays little role in the writings of Backhaus and Reichelt and they treat the question of revolution as outside their field of academic expertise' (Endnotes 2010, p. 99).[2] Nonetheless, it is possible to examine the practical implications of this approach by turning to the work of Werner Bonefeld who, as stated above, has not only introduced it into Anglophone Marxism, but also developed it further along resolutely political lines, i.e. by putting the revolutionary class struggle at the centre of his investigation (Endnotes 2010, p. 98).[3]

Bringing Politics into the Neue Marx-Lektüre: Bonefeld and Open Marxism

A recent article by Bonefeld on Adorno and social praxis is a fertile ground to discuss this issue. The starting point of Bonefeld's discussion is the recognition that in capitalism the 'subject's objectification exists in an inverted form, in which the thing subjectifies itself in the person, and the person objectifies him- or herself in the thing' (Bonefeld 2012, p. 125). In other words, Bonefeld takes up the Adornian insight, which originally triggered the *Neue Marx-Lektüre* (Reichelt 1982), that in this society individuals become determined as 'character masks' or 'agents of value': their social activity becomes the activity of 'personifications of economic categories' (Bonefeld 2012, p. 124). In more overtly Adornian terms, Bonefeld speaks of this phenomenon as involving a specific 'objective conceptuality', which 'holds sway in reality (*Sache*) itself' (Bonefeld 2012, pp. 125–6). However, unlike Backhaus and Reichelt, Bonefeld explicitly poses the question of the implication of this form-determination of human individuality for emancipatory praxis, i.e. for revolutionary class struggle:

> The critique of political economy is not satisfied with perpetuating the labourer. Its reasoning is subversive of all relations of human indignity. Subversion is not the business of alternative elites that seek revolution as mere conformist rebellion – a revolution for the perpetuation of wage slavery. Their business is to lead labour, not its self-emancipation. Subversion aims at general human emancipation (Bonefeld 2010a, pp. 62–3).

The interesting thing about Bonefeld's answer to this question is that, at least in principle, he explicitly rejects those attempts at grounding 'resistance' against reification in an 'asserted subject conceived in contradistinction to society', and whose transhistorical basis would be the worker's 'humanity and soul' (Lukács), 'the inner transcendence of matter' (Bloch), a 'materialist instinct' (Negt and Kluge), or biopower (Hardt and Negri) (Bonefeld 2012, p. 131). In other words, Bonefeld is at pains not to relapse into any exteriority to the perverted forms of existence of the social individual as the ground for the revolutionary subject:

> And Adorno? He would have none of this. The idea that there is a world out there that has not yet been colonized by the logic of things is nonsensical. Instead of a concept of society, these differentiations of society into system and soul/transcendent matter/materialist instinct/bio-power separate what belongs together (Bonefeld 2012, p. 131).

Bonefeld elaborates further on this through a 'philosophical' discussion of Hegel's conception of the relation between essence and appearance (Bonefeld 2012, pp. 127–8). Essence, he argues following Hegel, has to appear (it cannot choose not to do so). Moreover, this appearance is its (only) mode of existence. This means that there is no exteriority to essence's actual manifestation, however perverted the latter might be: 'its appearance is thus at the same time its disappearance' (Bonefeld 2012, p. 128). Translated into social theory, this philosophical argument means that human sensuous practice (essence) does exist as personification of economic categories (appearance), and that this inversion is no mere subjective illusion, but is all too real. Now, whilst this certainly allows Bonefeld to formally avoid relapsing into an externality between human subject and society, it begs the question as to how to avoid the political dead-end to which Adorno pessimistically succumbed? In other words, the question arises as to how to avoid the conclusion that 'there could be no such thing as emancipatory praxis because the reified world of bourgeois society would only allow reified activity' (Bonefeld 2012, p. 124)?

Here lies the crux of the matter, because, in my view, Bonefeld can remain true to the project of emancipatory praxis only by backtracking on his declamation to reject any exteriority between 'essence' and 'appearance'. Thus, right after claiming that the former vanishes in the latter, he endorses Adorno's claim in *Negative Dialectics* that 'objects do not go into their concepts without leaving a remainder' since 'the concept does not exhaust the thing conceived' (Adorno 1992, p. 13). According to Bonefeld, the critical move consists in 'opening the non-conceptual within the concept' (Bonefeld 2012, p. 130). This non-conceptual content, Bonefeld further argues, 'subsists within its concept but *cannot be reduced to it*' (Bonefeld 2012, p. 130, my emphasis). Crucially, *it is this moment of irreducibility of the content which, in its simplicity and unmediatedness, constitutes the ground of revolutionary subjectivity*. In other words, the latter is seen by Bonefeld as the expression of the direct affirmation of the ('non-conceptual') content. The fact that he does not see this affirmation as a pure positivity but only as negation of 'the negative human condition' (Bonefeld 2012, p. 130) makes no difference. The point is that the immediate 'source' of that negativity is located in the (formless) content itself: 'Subversion is able to negate the established order because it is "man" made' (Bonefeld 2010, p. 66). The postulate of immanence between content and form ultimately thereby remains just a formal declaration which is belied as the argument unfolds. In the end, an element of exteriority to alienated social practice creeps back in as the residual 'substance' of revolutionary subjectivity.[4]

We shall return below to the substantive shortcomings of this kind of approach. Here the important point to address is the implication of this conception of revolutionary subjectivity for the *meaning of science as critique*. Briefly put, for Bonefeld, dialectical critique comes down to the demystification of 'economic categories' by revealing their social constitution as perverted modes of existence of human activity, that is, by discovering sensuous practice as the negated content behind those reified forms of social mediation (Bonefeld 2001, pp. 56–9; and 2012, p.

127). What follows from this is that, for Bonefeld, the 'subversive' moment of Marx's methodological programme is essentially *analytic*: it consists in the discovery of the content of a determinate form. Drawing on the work of Backhaus commented on above (Bonefeld 1998), it is through *reductio ad hominem* that science as critique provides enlightenment on revolutionary practice.

The problem with this approach is, as argued elsewhere (Starosta 2008; Caligaris and Starosta 2014), that dialectical analysis is actually incapable of offering an *explanation* (hence comprehension) of the *raison d'être* of determinate concrete forms of reality. In moving 'backwards' from concrete form to content, dialectical analysis can at most reveal *what* are the more abstract determinations whose realisation is presupposed and carried by the immediate concrete form under scrutiny. But it cannot account for its 'why' (i.e. its fully unfolded immanent necessity). In this sense, although it does comprise a necessary methodological stage of dialectical research, the analytical discovery of the human content of fetishised relations between things can shed little light on the comprehension of revolutionary subjectivity. In fact, that was the scientific achievement of the Marxian critique of political economy as early as in the *1844 Paris Manuscripts*, which allowed him to grasp the *simplest* (human) determination behind the content and form of the abolition of the fetishism of capitalist social relations (Starosta 2015, Chapter 1). But the whole point of Marx's subsequent scientific endeavour was precisely to advance in the comprehension of the *further mediations* entailed by the material and social constitution of the revolutionary subject, which could only be the result of their *synthetic* ideal reproduction.

Evidently, this presupposes that one considers that there actually *are* further mediations that need to be unfolded synthetically in order fully to comprehend revolutionary practice. But this is what Bonefeld's approach denies. As I have argued, despite his critique of other perspectives that resort to the immediacy of 'an asserted subject externally counterposed to society', his own endeavour ultimately finds the immanent ground of revolutionary subjectivity in something simple and unmediated, i.e. the abstract materiality of 'sensuous human practice' which 'lives within and through relations between things'. Bonefeld's restriction of the subversive moment of dialectical critique to analysis is therefore perfectly coherent on this score. In his view, when it comes to revolutionary subjectivity, there are actually no *determinations* at stake, there is nothing to be explained. In other words, the revolutionary abolition of capital has no material, social or historical *immanent necessity* Bonefeld (2010, p. 64).[5] Its only 'necessity' is moral, the practical realisation of the 'communist categorical imperative of human emancipation' (Bonefeld 2010, pp. 66, 77). In brief, the revolutionary abolition of capital is the result of an abstractly free and socially autonomous political action, represented as the absolute opposite of the alienated automatism of the capital form (albeit one that can only exist as 'negativity', i.e. in the struggles 'in and against' capitalist oppression):

> The existence of the labourer as an economic category does therefore not entail reduction of consciousness to economic consciousness. It entails the concept of economy as an experienced concept, and economic consciousness as an experienced consciousness. At the very least, economic consciousness is an unhappy consciousness. It is this consciousness that demands reconciliation: freedom turns concrete in the changing forms of repression as resistance to repression (Bonefeld 2010, p. 71).

It follows that the only thing that actually requires explanation is the social constitution of the fetishised forms of objectivity in which human practice exists in capitalism. In this sense, Bonefeld acknowledges that the critical power of the dialectical method involves not only analysis, but also, fundamentally, synthetic or 'genetic' reproduction. Thus, in an article on the meaning of critique, he approvingly quotes Marx's methodological remark that

> It is, in reality, much easier to discover by analysis the earthly kernel of the misty creations of religion than to do the opposite, i.e. to develop from the actual, given relations of life the forms in which these have been apotheosized (Marx 1976, p. 494).

However, this synthetic reproduction is recognised by Bonefeld as the only materialist and scientific method for the genetic development of perverted social forms, i.e. for the social constitution of fetishised *forms of objectivity* out of human relations. As far as forms of *subjectivity* are concerned, they might at most be considered part of the genetic development of forms only insofar as individuals 'act rationally as executors of economic laws over which they have no control' (Bonefeld 2012, p. 128), which for this approach is the only aspect under which human beings act as personifications of economic categories. But as for *antagonistic* forms of subjectivity and action, they seem to fall outside the scope of the systematic unfolding of 'economic categories' (except, of course, as instances of negation of the latter's self-movement, i.e. as struggles *against* it). Thus, Bonefeld states: 'Does it really make sense to say that workers personify variable capital? Variable capital does not go on strike. Workers do' (Bonefeld 2010, p. 68). And they do so not as owners of labour power trying to secure the reproduction of their commodity. More importantly, the workers struggle daily against 'the capitalist reduction of human purposes to cash and product' (Bonefeld 2010, p. 72).[6]

In sum, for this kind of approach the synthetic movement of the dialectical exposition concerns the social constitution of 'economic categories' and the continuous process of reproduction of the constitutive premise of their existence at every turn of the conceptual development. Bonefeld locates this premise in the 'logic of separation' of labour from its conditions (Bonefeld 2011, p. 395), i.e. in the *formal subsumption of labour to capital*. But the systematic sequence does not entail any progress in the knowledge of the immanent determinations of revolutionary subjectivity. The significance that Bonefeld attaches to the culminating point of Marx's systematic exposition in Volume I of *Capital*, which for him should be better confined to the concept of *primitive accumulation*, is symptomatic in this regard.[7] The chapter on the 'historical tendency of capitalist accumulation' only matters insofar as 'it also continues the process of expropriation in its own terms, as capital centralization' (Bonefeld 2011, p. 394). As for the revolutionary expropriation of the expropriators and the bursting asunder of the capitalist integument that Marx posits as the necessary outcome of the alienated socialisation of private labour, Bonefeld considers that they should be left aside as 'desperately triumphal remarks' (Bonefeld 2011, p. 395). This should come as no surprise. As I have shown, according to his approach, revolutionary subjectivity is quite simply self-grounded in an abstract inner negativity, which is expressed, however 'contradictorily', in every manifestation of resistance to oppression.

At first sight, and in contradistinction to the 'fatalism' and 'quietism' entailed by orthodox perspectives that posit the supersession of capital in terms of the 'mechanic' impossibility of its expanded reproduction (i.e. the different versions of theories of capitalist breakdown), *Open Marxism* seems to extoll and 'empower' the political action of the working class. At the same time, this conception appears to avoid the lapse into the naïve immediatism and subjectivism characteristic of, for instance, so-called '*Autonomist Marxism*'.[8] However, I shall show in the next section that the *Open Marxist* perspective is also deeply problematic.

The limits of *Open Marxism*

The first fundamental substantive critical remark that can be made about the *Open Marxist* approach is that despite its valuable attempt to undertake an uncompromising and radical criticism of capitalist social relations in their totality, it ends up *naturalising* the *historically-specific social form of personal freedom* characterising the private and independent individual, i.e. the subjectivity of the commodity producer. As a consequence, this perspective cannot but lead to the practical impotence to abolish the fetishism of the commodity- and capital-forms of social relations. In order to substantiate this point, let us examine the matter more closely.

In effect, as Iñigo Carrera (2007, Chapter 3) forcefully argues in what I think is one of his most important contributions to the contemporary reconstruction of the Marxian critique of political economy, in capitalism free consciousness is neither the abstract opposite to nor the content of alienated consciousness. Instead, the consciousness that is free from all relations of personal subjection is but the mode in which the alienated consciousness of the commodity producer affirms through its own negation. In other words, the other side of the coin by which the human individual sees her/his social powers as the objective attribute of the product of social labour (i.e. value) is her/his self-conception as the bearer of an abstractly free, 'self-determining' subjectivity. Thus, it is by seeing herself/himself – and therefore practically acting – as abstractly free that the individual affirms and reproduces her/his alienated productive practice, that is, her/his social determination as personification of the objectified forms of the general social relation of production (the commodity, money, capital and so on).[9]

As Marx himself points out in the *Grundrisse*, the subjective form of personal freedom is but an expression of the fact 'that the individual has an existence only as a producer of exchange value' (Marx 1976, pp. 717–19):

> Therefore, when the economic form, exchange, posits the all-sided equality of its subjects, then the content, the individual as well as the objective material which drives towards the exchange, is *freedom*. Equality and freedom are thus not only respected in exchange based on exchange values but, also, the exchange of exchange values is the productive, real basis of all *equality* and *freedom.* As pure ideas they are merely the idealized expressions of this

> basis; as developed in juridical, political, social relations, they are merely this basis to a higher power. And so it has been in history. Equality and freedom as developed to this extent are exactly the opposite of the freedom and equality in the world of antiquity, where developed exchange value was not their basis, but where, rather, the development of that basis destroyed them. Equality and freedom presuppose relations of production as yet unrealized in the ancient world and in the Middle Ages. Direct forced labour is the foundation of the ancient world; the community rests on this as its foundation; labour itself as a 'privilege', as still particularized, not yet generally producing exchange values, is the basis of the world of the Middle Ages. Labour is neither forced labour; nor, as in the second case, does it take place with respect to a common, higher unit (the guild) (Marx 1993, p. 245).

Now, we have seen that despite *Open Marxism*'s valiant efforts to eliminate all exteriority between human productive practice and its alienated social forms of existence, when it comes to grounding the radical transformative powers of the working class, these authors end up reintroducing through the back door a 'moment' of subjectivity which is set into motion as an unmediated expression of the generic 'constitutive power' of human labour. Revolutionary action is thus not seen as undertaken by wage-workers in their alienated determination as *personifications* of their reified social being (i.e. capital). Instead, Revolutionary action becomes represented as *abstractly free* and the content of that freedom as working class *self-determination*. In other words, the source of the potentiality to achieve the revolutionary abolition of capital is seen as having no material and social determination other than the will of wage-workers who, through their irreducible refusal to subordinate their 'human dignity' to the 'cash nexus', unleash, albeit always in a 'contradictory' fashion (on which more below), the radical transformation of materiality of the social life-process.

This is openly manifest already in Bonefeld's early work (Bonefeld 1993, pp. 26-8), precisely in the way he appears to be at pains to overcome the externality between labour and capital extolled by 'Autonomist Marxists', without relapsing into a structural functionalism (e.g. Jessop 1991) that reduces class struggle to a form of the reproduction of capital and denies its capital-transcending potentialities (Bonefeld 1993, pp. 26–8). Bonefeld attempts to navigate through this antinomy by emphatically stressing the 'internal or dialectical relation' between labour and capital as one between material content ('the constitutive power of human practice') and its alienated mode of existence ('social reproduction as domination'). Thus, it follows from this (allegedly) immanent nexus between content and form that alienation permeates all capitalist social existence, so that the two poles cut across every manifestation of class struggle (indeed, the singularity of each human subject): there being no privileged form of action which can be said to express the affirmation of a pure non-alienated subjectivity. 'Reform' ('labour as a moment of social reproduction in the form of capital') and 'Revolution' are therefore seen as constituting 'extreme poles of a dialectical continuum that social practice represents' (Bonefeld 1992, p. 102). However, in what I think is key to the argument of this paper, Bonefeld explicitly characterises the revolutionary moment of 'transcendence' as a 'process in and against capital *in terms of working class self-determination*', so that the resolution of the 'dialectical continuum' between 'Reform' and 'Revolution' is not determined but is 'open to the process of struggle itself' (ibid., *my emphasis*). In other words, this discussion makes evident that *Open Marxist*s consider that the moment of 'transcendence' (i.e. revolutionary subjectivity), even if always intertwined with 'integration' (the determination of the wage worker's alienated subjectivity as personification of the reproduction of capital), ultimately is the expression of working-class self-determination, that is, as an element of subjectivity that is not a mode of existence of (hence determined by) the capital form. The specifically revolutionary resolution of the class struggle is thereby seen as an *unmediated* assertion of this undetermined, residual and pristine human content lurking behind the fetishised social forms of capitalist society.

This leads us to a further weakness of the *Open Marxist* approach, which is of a more methodological dimension. Specifically, I think that despite the recurring insistence on 'internal or dialectical' relations, this perspective actually entails an external representation of the immanent nexus between the content and concrete form of revolutionary subjectivity in terms of a 'pseudo-dialectic' consisting in the 'unity of opposites'. This becomes apparent in its treatment of the notion of contradiction, which is usually initially postulated correctly (at least formally) as the self-negating form of existence of a determinate content (hence as the *self-movement of affirmation through negation*), but which then surreptitiously turns, in the very course of the same argument, in the 'intertwining' of two different *immediate affirmations*, extrinsically united in a process of 'struggle between antagonistic opposites' (Iñigo Carrera 2013, Chapter 1; Starosta 2015, Chapter 3). Although this should be already clear from Bonefeld's passages discussed above, it is thrown into even sharper relief in the work of Richard Gunn, who offers the most rigorous and in-depth methodological discussion within the *Open Marxist* tradition. Interestingly and relevantly for the theme of this section, in what is a foundational article from this perspective, Gunn poses the question in terms of the contradictory relationship between freedom and alienation in capitalist society.

Gunn's point of departure is in itself already problematic, insofar as he overtly postulates 'freedom *qua* self-determination' as a general, hence transhistorical, feature of the human species being, this being what distinguishes the latter from other natural forms of the material world (Gunn 1992, p. 28). But what is actually of interest here is the way in which he confronts the question of alienation in capitalism and its revolutionary overcoming, which is posed by Gunn as involving the following paradox:

> If we move *freely* then we were not unfree to begin with, but if we move unfreely then freedom (at any rate in the sense of self-determination) can never be the result (ibid., p. 29).

The 'trick', Gunn continues, 'has to be to see unfreedom as a mode of existence of freedom' (ibid.). In this sense, he concludes that in reality there is no such thing as *un*freedom, but 'unfree freedom, freedom subsisting alienatedly, i.e. in the mode of being denied' (ibid.). In brief, and leaving aside for the moment the inverted form in which he represents the nexus between 'freedom *qua* self-determination' and alienation in capitalism, it is clear that so far his argument revolves around the self-negating affirmation of a determinate content in its concrete form of realisation, that is, the movement of contradiction.

How, according to Gunn, does this contradiction between the essential content of freedom of human subjectivity and its alienated mode of existence develop into the form of a revolutionary action that puts alienation to an end? In order to examine this question, let us now turn our attention to a more recent article (co-authored with Adrian Wilding) in which, in the context of a sympathetic critical assessment of John Hollow's book *Crack Capitalism* (Holloway 2010), the two authors revisit and elaborate further this question (Gunn and Wilding 2012; see also Gunn and Wilding 2014). The terms of the problem remain the same, albeit now approached from a slightly different angle: the apparent antinomy that they track down in Holloway's book between what they call the 'attractive' view of revolution, according to which freedom already exists in a pristine and undistorted form in a pre-revolutionary situation (thus making the revolutionary task clearly possible but all too simple and voluntarist), and the 'unattractive' view, which assumes that freedom is literally absent in a pre-revolutionary situation (which sounds more 'realistic' but, according to these authors, makes it impossible for freedom to be the result of revolution) (Gunn and Wilding, pp. 178-80). The solution to this antinomy is, in line with Gunn's argument reviewed above, to acknowledge *both* that revolution effectively is an act which ends voluntary servitude and therefore 'is an expression and articulation of already-free action' (Gunn y Wilding 2012, p. 178) *and* that in a pre-revolutionary social world, such freedom exists but in a 'distorted' or 'self-contradictory and alienated' form (Gunn y Wilding 2012, pp. 181–2). Thus, the question is seen as involving a transition from a situation in which freedom already obtains but in an alienated form (pre-revolutionary situation), to a situation in which freedom exists in an uncontradicted and non-alienated from (revolution) (Gunn y Wilding 2012, p. 182). In other words, for Gunn and Wilding, mediation only pertains to capital-reproducing 'moments' of subjectivity, but not to the revolutionary 'pole of the continuum', which is seen as an affirmation of the human being's innately free self-determining subjectivity that 'breaks through' its alienated 'integument'.

This shows very clearly in the way they conceptualise 'uncontradicted self-determination', in a twofold sense. In the first place, when they claim that in a generally non-revolutionary situation, such an uncontradicted self-determination already makes its appearance within an alienated society, albeit in a 'proleptic or prefigurative' fashion, in and through 'islands of mutual recognition' in the 'cracks and fissures' of a contradictory social world (Gunn and Wilding 2014). Out of the blue, human life is now turned into the *unity of two intertwining opposites*: an alienated pole for the greater part of social existence and a free one in those 'islands of mutual recognition'. In the second place, it is noteworthy how they construct their concept of freedom on the basis of Hegel's concept of recognition as played out in the Master-Slave dialectic from Chapter IV of his *Phenomenology of Spirit* and further developed historically in Chapter VI, which culminates with the discussion of patterns of recognition in the French Revolution. In other words, they construct the ground of the communist revolution based on a conceptual framework whose actual content is but the emergence and concrete development of the modern, capitalistic 'self-determining' freedom of the commodity owner out of relations of personal dependence, which is ideologically presented by Hegel in an inverted fashion as the movement of an abstract individual self-consciousness deprived of social determinations.[10] As a consequence of all this, their critique of Holloway's occasional appeal to a 'pristine' or 'undistorted' freedom is thus limited to noting that 'such an immediacy that lies outside alienation's realm' cannot be taken 'as starting point' for the search for the genesis of revolutionary subjectivity within a non-revolutionary situation (Gunn and Wilding 2012, p. 184), yet it does constitute the 'key' to (i.e. the content of) its interstitial emergence and eventual proliferation. Hence, despite their best efforts, *Open Marxist*s end up sneaking an abstractly free subjectivity through the backdoor as the ground for the revolutionary transformation of society. In the end, the difference from the Autonomists comes down to a more sober and cautious *subjective attitude* when assessing 'really-existing' working-class struggles. Against the 'euphoric and triumphalist poetry that prevails in various *Autonomia*-influenced accounts', Gunn and Wilding's *Open Marxist* perspective 'allows for respect for a reality principle (in Freud's sense)' (2012, p. 182), a 'word of warning' about the 'difficulties' and 'complexities' involved in revolution. But the ground of revolutionary subjectivity in an abstractly free and self-determined subject remains the same.

Now, from where does this notion of free (*qua* self-determining) subjectivity by nature, which constitutes for these Marxist authors the content of revolutionary action, arise? Certainly not from the imagination of the theorist. When looked at more closely, we can realise that it is in fact the concrete form of the alienated consciousness abstracted from its content and transformed into its 'logical' opposite. It is from that apparent exteriority that free subjectivity is posited as the source of the revolutionary negation of alienated subjectivity. Emancipation is positioned as the removal of the inevitable external coercion imposed by social objectivity upon the natural self-determination of apparently free consciousness. In other words, that reading aspires to get rid of the commodity, money, capital and the state *precisely on the basis* of the immediate affirmation of the concrete form of the most general subjective form of existence of alienated human practice which is the necessary complement of those forms of objectivity, namely: the personal freedom of personifications of commodities.[11] Which is, quite simply, an oxymoron. In sum, the connection between science as critique and the abolition of the fetishism of capitalist social relations needs to be approached differently. In the next section, we propose and develop such an alternative perspective.

Commodity fetishism and science as practical critique

As anticipated in the introduction, I think that a fruitful alternative perspective can be found in the substantive and methodological contributions of Iñigo Carrera to the critique of political economy. According to this reading, the question of science as critique must be approached in a radically different manner. More concretely, it is about a development of the dialectical method which, insofar as it recognises knowledge's own immanent material determination as the organisational 'moment' of human action, gives science the specific form of *practical critique*. In this sense, the proper starting point and immediate object of the dialectical critique of political economy is the question about the conscious organisation of the radical transformative action which aims at revolutionising the forms of social life. This means that it is not just a question of the centrality of class struggle as the fundamental 'substantive abstraction' that constitutes the *object* of an abstractly theoretical process of cognition, which therefore renders it inevitably external to practice, despite rhetorical claims to the contrary in the name of the 'immanence of theory within its object' (Gunn 1992; Bonefeld 1992, 1995). Instead, it is a matter of the scientific inquiry into the conscious self-organisation of one's own transformative action in its singularity, albeit acknowledged as an individual organic moment of such radical collective action. To put it differently, at stake in radically critical scientific cognition is the objective knowledge of the social determinations, the immanent necessity, of our own individual action beyond any appearance (Iñigo Carrera 1992, p.1). Only on this basis is it possible to attain the voluntary revolutionary transformation of the social world.

From the standpoint of the scientific-critical method which is necessary for the immanent discovery of revolutionary subjectivity, both the *Neue Marx-Lektüre* and the *Open Marxist* approach conceive of the 'defetishising' moment of the critique of political economy as limited to the analytical movement of '*reductio ad hominem*' by which cognition traces the human origins of objectified forms of capitalist social mediation. However, at least with regards to knowledge of the grounds of revolutionary subjectivity, the properly *critical* moment of dialectical research is exhausted in the exposition of the most simple and general expression of capitalist alienation, that is, in the 'fetishism of commodities'. By contrast, my own alternative perspective on Marx's dialectical investigation of the determinations of the commodity form (commodity fetishism included) leads to a different conclusion regarding the connection between revolutionary praxis and these simpler fetishised forms of the general social relation of production which mediate the unity of social life.

True enough, in this process of cognition we become aware of the human content of the objective social powers borne by the commodity. However, what follows from this insight is not that we therefore immediately carry the power to negate the commodity form of our general social relation. Rather, it follows that whatever power we might have to radically transform the world must be a concrete form of the commodity itself. Yet, far from revealing the existence of that transformative power, the abstract determinations of social existence contained in the commodity form show no potentiality other than the reproduction of that alienated social form. So much so that the free association of individuals (the *determinate* negation of capitalism) appears in Chapter 1 (incidentally, precisely in the section on fetishism) as the *abstract* opposite of value-producing labour and hence, as the *extrinsic* product of the *imagination* of the subject engaged in that process of cognition. Thus, Marx starts that passage referring to communism by saying 'let us finally *imagine* …' (Marx 1976, p. 171, *my emphasis*).

Thus, the defetishising critique of revolutionary science does not simply consist in discovering the constituting power of a generic human practice as the negated content of capitalist alienated forms, which would constitute the ground for our revolutionary transformation of the world. Rather, it involves the production of the self-awareness that the reproduction of human life in all of its moments, *including our transformative action*, takes an alienated form in capitalism. The immediate result of the demystifying critique of the fetishism of commodities is to become conscious of our own alienated existence, i.e. of our determination as personifications or 'character masks'. This *is* our general social being and there is no exteriority to it. Fetishism is total which, in turn, means the social powers of our transformative action are effectively borne by the product of labour and we cannot but personify them.

This obviously bears on the question discussed earlier on the relationship between alienation and freedom. Specifically, this means that upon consciously discovering the social basis of the value form, we do not cease to be determined as its personifications and become able to affirm an abstractly free self-determining action. What this discovery changes is, as Iñigo Carrea puts it, that our social determination as personification of the commodity no longer operates behind our backs (Iñigo Carrera 2007, p. 204). In this way, we do affirm our freedom. However, we do so not because we realise that 'in reality' we are free beings by nature and could thereby 'choose' to 'stop making capitalism' if we tried hard enough, i.e. if we *turned our backs* on our social being (Cf. Holloway 2010). Instead, through the critical investigation of the value form we affirm our freedom because we come *consciously to cognise* our own determination as alienated social subjects (Iñigo Carrera 2007, p. 204). Armed with that objective knowledge of the alienated nature of our subjectivity, we could *consciously act upon* those alienated determinations in order to transform them in the direction of their revolutionary transcendence. Still, this would only be possible if those determinations actually carried the objective potentiality for their self-abolition, which is something that the simple commodity form of social relations does not show. This does not mean that commodity fetishism cannot be abolished. It only signals the need to move forward in the dialectical investigation of the more concrete social determinations of its revolutionary abolition.

Perhaps a good way to clarify this argument is by examining a methodological external remark that Marx introduces when discussing the function of money as means of payment in the 1859 *Contribution to the Critique of Political Economy*. It is worth quoting that profoundly rich text at length:

> But the metamorphosis of commodities, in the course of which the various distinct forms of money are evolved, transforms the commodity-owners as well, and alters the social role they play in relation to one another. In the course of the metamorphosis of commodities the keeper of commodities changes his skin as often as the commodity undergoes a change or as money appears in a new form. Commodity-owners thus faced each other originally simply as commodity-owners; then one of them became a seller, the other a buyer; then each became alternately buyer and seller; then they became hoarders and finally rich men. Commodity-owners emerging from the process of circulation are accordingly different from those entering the process. The different forms which money assumes in the process of circulation are in fact only crystallisations of the transformation of commodities, a transformation which is in its turn only the objective expression of the changing social relations in which commodity-owners conduct their exchange. New relations of intercourse arise in the process of circulation, and commodity-owners, who represent these changed relations, acquire new economic characteristics (Marx 1987, p. 371).

This passage could be read as a kind of *dynamic* development of the alienated determination of human productive individuality, whose simplest expression Marx presented through the discussion of the fetishism of commodities. As I have argued elsewhere (Starosta 2015, Chapter 5), in the latter text Marx unfolds the way in which the productive consciousness of the private individual unconsciously posits its own immanent determinations in the external form of the value-objectivity. Subsequently, he shows how the very subjectivity of the commodity producer becomes determined as the personification of those objectified forms of social mediation it had unconsciously engendered. What we have here is a statement of the transformative dynamics structuring the constitution of novel forms of subjectivity as an expression of the further concretisation of the 'law of value' beyond its simplest form. It is, as it were, the 'law of private subjectivity' that regulates the development of further concrete forms in which human beings act as 'personifications of economic categories'.

Certainly, those more complex forms in which the movement of value attains unity remain 'only the objective expression of the changing social relations in which commodity owners conduct their exchange', i.e. their simplest (social) content remains the general productive relation between human beings. However, the real inversion of those social relations as attributes of things means that human beings cannot consciously control the self-transformation of their subjectivity (at least not with the determinations unfolded up to that point). This transformation thereby occurs 'behind their back' as a result of the self-movement of the alienated forms of objectivity through which their social metabolic process takes place. As those objectified forms self-develop and change, commodity owners 'who represent these changed relations, acquire new economic characteristics', i.e. they progressively emerge from the circulation process wearing different 'character masks' from those with which they entered.

In the passage above, Marx specifies the forms of subjectivity that have emerged up to that particular stage of his presentation. More concretely, he mentions the figure of simple commodity owner, buyer and seller, hoarder and rich man. However, the implication of this discussion is that commodity owners shall undergo further 'changes of skin'. Thus, a few pages later he develops the figure of debtor and creditor (Marx 1987, p. 373), noting also how the corresponding general ideological forms change as well. From religion as the ideological form corresponding to the hoarder, we now move to jurisprudence as the one corresponding to the subjective form of creditor (ibid.). Furthermore, 'as money develops into world money, so the commodity owner becomes a cosmopolitan', the general ideological form of which is that of 'cosmopolitanism, a cult of practical reason, in opposition to traditional religious, national and other prejudices which impede the metabolic process of mankind' (Marx 1987, p. 384).

The fundamental point of this discussion is that those passages from the 1859 *Contribution* bring out very nicely a fundamental aspect of Marx's 'systematic dialectic': it includes both the forms of *objectivity and subjectivity* of capitalist society. But additionally, they implicitly contain important methodological insights into the way in which the genesis of different forms of subjectivity should be materialistically investigated, namely, as necessary mediations of the autonomised self-movement of forms of objectivity. This, I think, is the only method which allows us *immanently* to ground forms of consciousness and will (i.e. subjectivity) *within* the movement of present-day social relations. Crucially, my central claim is that if we want to stay true to this materialistic approach, this method should not only 'apply' to 'value-reproducing' forms of subjectivity and action, *but must also include revolutionary subjectivity as well*. In other words, the form of 'revolutionary political subject' (more specifically, of our own subjectivity as an individual organ of such a collective class subject) must be immanently unfolded as a much more developed mode of existence taken by the original commodity owner with which the dialectical exposition started.

To put it in more general terms, *the immanent ground of revolutionary subjectivity is not simple and unmediated*. Instead, it is a 'unity of many determinations', which therefore means that its scientific comprehension can only be the result of a complex dialectical investigation involving both the analytic movement from the concrete to the abstract, and the synthetic, mediated return to the concrete starting point, i.e. revolutionary transformative action. Dialectical research must therefore analytically apprehend all relevant social forms and synthetically reproduce the 'inner connections' leading to the constitution of the political action of wage labourers as the form taken by the revolutionary transformation of the historical mode of existence of the human life process.

Now, if the 'reproduction of the concrete in thought' shows that the determinations immanent in the commodity form do not carry, in their simplicity, the necessity of transcending value-production, the search for the latter must move forward unfolding the subsequent concrete forms in which the former develop. Our process of cognition still needs to go through more mediations in order to become fully aware of the necessity of our action in the totality of its determinations, i.e. beyond any appearance presented by it. In order to develop the plenitude of its potentiality, this conscious development must reach a concrete form of our alienated social being which embodies a determinate potentiality whose realisation: (a) entails the abolition of alienated labour itself; and (b) has our transformative action as its necessary concrete form. In sum, revolutionary action must personify a concrete determination of value-producing human practice; a determination, however, whose realisation precisely consists in the abolition of value production itself.

In this sense, far from exhausting science's 'critical-practical moment', the ideal reproduction of the commodity form and its fetish-character (in the unity of its analytic and synthetic phases) is thereby but the *first step* in the broader process of dialectical cognition through which the subject of revolutionary transformation discovers the alienated character of her/his social being and, consequently, of her/his consciousness and will (including her/his transformative will). However, this process also produces the awareness of the historical powers developed in this alienated form and, consequently, of the revolutionary action that, as sheer personification of 'economic categories', the emancipatory subject needs to undertake (Iñigo Carrera 2013). Such development of those subsequent determinations whose unity underlies the constitution of the working class as revolutionary subject obviously exceeds the scope of this paper. However, by way of conclusion, in the final section I sketch out the essential moments of the systematic-dialectical unfolding of the movement of the capital form whose historical tendency leads to the necessity of its self-abolition in the concrete form of the radical transformative action of the proletariat.[12]

Concluding remarks: from the commodity to the revolutionary subject

I pointed out earlier that, from a materialist perspective, the necessity underlying the social constitution of the revolutionary subject should immanently derive from the unfolding of the potentialities of the commodity producer from which the dialectical exposition started, which make the latter undergo a 'change of skin'. However, the transformations at stake are not exhausted with those commodity producers's experience as a result of the subsequent determinations of the general circulation of commodities as such. In fact, the very development of the full potentialities of the general commodity circulation process shows that their realisation involves their self-transcendence into an internal moment of the circulation of capital (Marx 1976, pp. 247–50). In becoming capital, value – the materialised social relation of the private and independent individuals – turns into the concrete *subject* of the process of circulation of social wealth. In turn, the commodity and money, the particular and the general mode of existence of mercantile wealth, become determined as transitory forms which value-as-capital takes in its process of self-expansion (Marx 1976, p. 255). The alienation of the human individual thus reaches a new stage. It is not only about a process of social production mediated by the value form of the product. Nor is it even about one that simply has value as the direct *object* of the exchange process. The objectified abstract labour represented as the exchangeability of commodities has taken possession of the potencies of the process of circulation of social wealth itself. This moment of the human life process is turned into an attribute of the life cycle of capital, which has the production of more of itself, i.e. its *quantitative* increase or the production of *surplus value*, as its only general *qualitative* determination.

Now, although having circulation as its point of departure and hence with this sphere as one of its moments, the process of value's self-expansion pushes beyond circulation itself. The movement of capital shows the necessity to find within the circulation of commodities a commodity whose use value for capital is to produce more value than it costs. The existence of the doubly free worker provides capital with this requirement (Marx 1976, p. 270). As an independent human being, this worker can freely dispose of her/his individual productive powers (Marx 1976, p. 271). However, insofar as she/he is deprived of the objective conditions in which to externalise her/his personally-free subjectivity, she/he must give her/his labour power the form of a commodity to be sold on the market to the immediate personification of capital (Marx 1976, p. 272). As stated above, it is through the appropriation of the use value of this peculiar commodity that capital is able to valorise itself. The exposition must therefore develop the determinations of the process of consumption of labour power, which takes place 'outside the market' (Marx 1976, p. 279). In this way, Marx's presentation demonstrates how capital not only becomes the subject of the process of circulation of social wealth, but also turns into the formal subject of the labour process, which it subsumes as the material bearer of its self-valorisation. And this means that the production of use values, *hence of human life*, has ceased to be the immediate content of the movement of social reproduction and has become the unconscious or 'blind' outcome of the production of surplus value, that is, of the *alienated content* presiding over the movement of modern society. This is where the formal specificity of capital as an *indirect*, hence *fetishised*, general social relation resides. From this point onwards, the dialectical exposition will show that individuals, *precisely* for being the *material* subjects of this process (rather than 'in spite of'), shall become fully *form-determined* as personifications of different determinations emerging out of the movement of value's self-valorisation.

Thus, with the development of the content of the general social relation into the process of capital's self-valorisation, commodity owners who 'who represent these changed relations, acquire new economic characteristics'. In the first place, they become differentiated, respectively, into personifications of money-as-capital (the capitalist) and the commodity labour power (the wage-worker). Secondly, given the peculiarity of this latter commodity, the antagonism immanent in the purchase of labour power transcends the circulation process and carries over into the conditions of appropriation of its use value in the direct process of production, i.e. into the determination of the *normal* duration of the working day (Marx, 1976, pp. 342-3). Furthermore, this analysis shows that the realisation of the *full value* of labour-power, and therefore its long-term reproduction in the very conditions that capital in general (as opposed to the individual capital) demands from the wage worker as the only source of surplus value, is not independent from the determination of the *extensive* magnitude of its productive consumption (Marx 1976, p. 343). The purchase of the commodity labour power can thereby only be resolved by making the antagonistic relationship between its buyer and seller transcend its merely individual character in order to take the concrete form of *class struggle* (Marx 1976, pp. 344ff). The latter thus becomes determined as the most general *direct* social relation between *collective personifications of commodities* which mediates the establishment of the unity of the essentially *indirect* relations of capitalist production ruled by the valorisation of capital. In other words, though clearly an 'endemic' reality of the capitalist mode of production, the class struggle is not '*ontologically*' but *socially* constitutive of capitalism, since capitalists and wage-workers, *as owners of commodities* (not as embodiments of ontologically different principles of social reproduction), personify social determinations of the process of valorisation of capital whose realisation is antagonistic. More generally, this implies that the determinations implicated in the mere existence of labour power as commodity, or the merely *formal subsumption* of labour to capital, do not give the class struggle the transformative potentiality to go beyond the capitalist mode of production. In this simple determination, the political action of the working class only exists as a necessary concrete form of the *reproduction* of capitalist social relations and not of its revolutionary overcoming.[13]

As a matter of fact, the unfolding of the sequence of form determinations shows that the socio-historical genesis of the emancipatory subject can actually be found in the transformations in the *materiality* of social life brought about by the *real subsumption* of humanity to capital; more specifically, in the concrete form of *large-*

scale industry which constitutes capital's most developed method of production of relative surplus value. In effect, as Marx shows in *Capital* and the *Grundrisse*, through the constant revolution in the material conditions of social labour, capital transforms, contradictorily but progressively, the productive subjectivity of wage workers according to a determinate tendency: they eventually become *universal labourers*, that is, organs of a directly collective productive body capable of self-consciously ruling their individual participation in the social metabolic process by virtue of their power scientifically to organise the production process of any system of machinery and, therefore, any form of social co-operation.[14] In other words, the *alienated* social necessity arises for each individual member of the collective labourer to be produced as a subject that is fully and objectively aware of the social determinations of her/his individual powers and activity and who therefore consciously recognises the social necessity of the expenditure of her/his labour power in organic association with the other producers. However, this form of productive subjectivity necessarily collides with a social form (capital) that produces human beings as *private and independent individuals* who consequently see their general social interdependence and its historical development as an alien and hostile power borne by the product of social labour. The determination of the material forms of the labour process as bearers of objectified social relations can no longer mediate the reproduction of human life. *Capital accumulation must therefore come to an end and give way to the free association of individuals*. This is the inner material *content* of social life which is expressed in the *form* of the political revolutionary subjectivity of workers.

In sum, it is the historically-determined necessity for the all-sided and directly social development of the universality of productive attributes of workers beyond its capitalist 'integument' – though generated by the alienated movement of capital itself – that is realised in the concrete form of the communist revolution. And this means that *the revolutionary political consciousness of the working class can only be a concrete mode of existence of their productive consciousness*. In other words, what the revolutionary movement realises (its content) is, fundamentally, the transformation of the materiality of the productive forces of the human individual and, *therefore*, of their social forms of organisation and development. It is about a *material* mutation of the production process of human life, which takes concrete shape through a *social* transformation, which, in turn, expresses itself through a *political* action.

On the other hand, this also means that revolutionary powers are not 'self-developed' by the workers, but are an alienated attribute that capital puts into their own hands through the transformations of their productive subjectivity produced by the alienated socialisation and universalisation of labour through which the production of relative surplus value takes place. This is the reason why *revolutionary consciousness is itself a concrete form of the alienation of human powers as capital's powers*. The abolition of capital is not an abstractly free, self-determining political action, but one that the workers are *compelled* to undertake as *personifications* of the alienated laws of movement of capital itself. When the workers consciously organise the revolutionary abolition of the capitalist mode of production, they do so not as the incarnation of the powers of an abstract human practice deprived of social determinations, but as 'character masks' or 'representatives' of the inverted existence of the powers of their social labour, i.e. capital. The point is that it is an alienated action that *in the course of its own development* liberates itself from all trace of its alienated existence. Paraphrasing the above-quoted passage from the *1859 Contribution,* individuals 'emerging from the reproduction process are accordingly different from those entering it'. They enter it as wage workers personifying capital's need to produce relative surplus value. Yet, in the course of the revolutionary action they undertake as such personifications, they 'change skin' and emerge as consciously (thus freely) associated fully developed social individuals. In this sense, what sets capital-transcending political action apart from capital-reproducing forms of the class-struggle is its specific determination as a political action that is fully conscious of its own alienated nature, i.e. of personifying a necessity of capital. However, by becoming conscious of their determination as a mode of existence of capital, revolutionary workers also discover the historic task that as fully conscious yet alienated individuals they have to undertake: the supersession of capital through the production of the communist organisation of social life.

Finally, let us briefly draw the main implications of all this for one of the central methodological issues on which this paper has focused, namely, the determination of *science as critique*. In a nutshell, this discussion suggests that the content and product of the process of cognition entailed by the critique of political economy is therefore not the awareness of the *external circumstances* of a self-determining action. Instead, it is the self-awareness of the *inner material and social determinations* of our own alienated transformative action. Thus, dialectical social science does not look outside our action in order to comprehend the 'objective conditions' that 'constrain' its abstractly free affirmation, but rather, in penetrating its immediate appearances (including that of being abstractly free), goes right 'inside' it.

In this way, the field of human practice is never abandoned. Moreover, only by virtue of its *dialectical form*, involving both its analytic and synthetic moments, does the critique of political economy become determined as the fully conscious organisation of human practice in the capitalist mode of production and, hence, as the revolutionary science of the working class (Iñigo Carrera 2007, pp. 7-8).

---

[1] For a concise historical and intellectual contextualisation of the *Neue Marx-Lektüre* in English, see Endnotes 2010 and Bellofiore and Riva 2015.

[2] It goes without saying that the treatment of the question of revolution as 'outside their field of expertise' by scholars whose research programme revolves around the Marxian notion of *critique* seems quite odd, to say the least. The real reason seems to reside at a deeper level and is actually political. As *Endnotes 2* further remark: 'Most accounts of the *Neue Marx-Lektüre* understand as one of its main characteristics to be a rejection of Marx's attribution of an historical mission to the proletariat and a sensibility of scepticism towards the class struggle has been prevalent on the German Left' (2010, p. 98). Moreover, although seldom discussed explicitly by these scholars, there are certain passages in their work which give the impression that they would tend to locate the source of revolutionary subjectivity in a moment of human individuality which transcends its alienated existence as 'character mask': 'Marx presents the humans themselves only insofar as they have intercourse with one another as character masks. Insofar as they come into relation with one another as individuals, they are not the object of the theory. Insofar as they act as individuals, they withdraw from the building of theory in this specific sense; there they anticipate something which still has to be constructed' (Reichelt 1982, p. 168). If my reading is correct, rather than simply residing 'outside their field of expertise', for these scholars revolutionary subjectivity would lie outside the scope of the dialectical presentation of 'economic categories'.

[3] For an earlier assessment of the relation between value-form theory, systematic dialectics and revolutionary politics, see also the discussion provided by Eldred 1981.

[4] In more concrete terms, Bonefeld puts it as follows: 'For example, the conceptuality of the wage-labourer as a personification of variable capital entails what it denies. It denies sensuous practice, and this practice is immanent in the concept wage-labour. Sensuous practice exists within the concept of variable capital in the mode of being denied – sensuous practice cannot be reduced to the concept of variable capital – it subsists within its concept but cannot be reduced to it. Further, for variable capital to function, it requires the ingenuity and spontaneity of human purposeful practice. Yet, this too is denied in its concept' (2012, p. 130). The revolutionary class struggle is seen by Bonefeld as an expression of that sensuous human practice that 'variable capital' denies. In actual fact, his point seems to be that all struggles by workers express something more than their social determination as personifications of 'variable capital', namely, their 'human social autonomy' and 'freedom'. That is why they can always potentially develop, in and of themselves (i.e. not as expressions of any concrete social determination), into communist struggles. See: Bonefeld 2010a, pp. 68–72.

[5] Taking at face value the orthodox Marxist *mechanistic* (hence extrinsic) notion of determination of subjectivity for the only available one, Bonefeld can only see in the idea of historical necessity an accommodating and passive attitude towards the alienated laws of motion of capital. It can never be

the point of departure for the conscious organisation of its practical abolition: 'The future that will come will not result from some objective laws of historical development but will result from the struggles of today. The orthodox argument about the objective laws of historical development does not reveal abstract historical laws. It reveals accommodation to "objective conditions", and derives socialism from capitalism, not as an alternative but as its supposedly more effective competitor. There is no universal historical law that leads humankind from some imagined historical beginning via capitalism to socialism. Neither is history on the side of the working class. History takes no sides: it can as easily be the history of barbarism as of socialism' (Bonefeld 2010a, pp. 63–4).

[6] Strictly speaking, workers do not go on strike as 'variable capital', but as owners of the commodity labour power. Be that as it may, the point is that they do it in full accordance with their alienated social being as 'executors of economic laws that they cannot control' and not in 'defiance' of them.

[7] It is also symptomatic that in his otherwise rigorous, stylised reconstruction of the systematic sequence of Marx's exposition in *Capital,* Volume I, the concrete forms of production of relative surplus value are absent (Bonefeld 2011b, pp. 392–5). As we shall see later on, it is precisely in those chapters on the *real subsumption of labour to capital* that Marx unfolds (albeit incompletely) the determinations of revolutionary subjectivity.

[8] Perhaps the most paradigmatic expression of the grounding of revolutionary action in a pure 'autonomous creativity' of the subject within Marxism can be found in the Autonomist's 'inversion of class perspective' centred on the concept of working-class 'self-valorisation', which designates the self-determined positive power to constitute new practices outside capitalist social forms (Cleaver 1992, pp. 128ff; De Angelis 2007, pp. 225ff). Furthermore, this pure affirmation of the working class as autonomous subject is considered as (onto)logically prior to its 'co-option' or 'repression' by capital, deliberately represented, in line with post-structuralist thinking, as an external and self-constituting 'disciplinary' power (Hardt 1993). Thus, according to De Angelis, the theoretical starting point for the understanding of revolutionary subjectivity must be the self-sustaining *affirmation* of the multiplicity of needs, aspirations, affects and relations of human subjects (De Angelis 2005).

[9] Note in this regard that from a materialist standpoint the meaning, content and scope of freedom can only derive from its role in the organisation and development of human *productive* subjectivity. It follows that complete freedom does not consist in the absence of all social determination (hence *necessity*) in the affirmation of human individuality (with alienation thereby conceived of as the external imposition of social relations of objective compulsion that would 'constrain' an otherwise naturally and absolutely self-determining subjectivity). Instead, fully-developed freedom consists in the self-conscious control by each human being over the *twofold immanent* character (individual and social) of her/his productive action, that is, over her/his *individual* participation in the *inherently social* process of human metabolism. Thus considered, the simplest *material* determination of the personal freedom of the private and independent producer consists in the full conscious control of the individual character of human productive action at the expense of all conscious control over its immanent general social character (Iñigo Carrera 2007, pp. 51ff.). In this sense, the overcoming of the fetishism of capitalist social relations entails the progressive *transformation of the very historical and social form of human freedom*, whose *material content or substance* thereby involves the '*aufheben*' of the personal freedom of the private and independent producer. In other words, while *preserving* the full conscious control over the individual determinations of human labour, *each working subject* must *also* be *materially-equipped* with the *full conscious knowledge* of the social determinations of her/his individual labour. Only under these circumstances, 'expending their many different forms of labour-

power in full self-awareness as one single social labour force', and hence *rationally recognising the necessity* to affirm their own subjectivity as individual organs of a directly collective productive body, can the human life process eventually take the historical form of an 'association of free men [*Mensch*]', which consequently overcomes the fetish-character of the commodity as the general objectified form of social mediation (Marx 1976, p. 171).

[10] In this context, it comes as no surprise that Gunn and Wilding also draw inspiration from La Boétie's *Discourse on Voluntary Servitude*, an author from the mid-sixteenth century who is evidently confronting the question of the dissolution of *direct* relations of authority and subjection between human beings in the face of the expansion (probably unstoppable by that stage) of the commodity as the *general indirect* form of social mediation. Indeed, the voluntary servitude which the *Discourse* discusses and aspires to put an end to is that which is subject to the *personal* power of the 'tyrant'. In other words, the *Discourse* is but a very early ideological expression of the historical emergence of the personal freedom of the personifications of commodities (whereas Hegel's *Phenomenology* is a later expression of its consolidation and generalisation).

[11] Some authors do develop and subject to criticism the notion of bourgeois individuality. But the latter is reduced to *individualism*, that is, to the *atomistic* affirmation of that abstractly free subjectivity. Hence, the collective, solidaristic affirmation of that very same subjectivity in the form of class struggle is seen as the absolute opposite of alienated subjectivity (or, at least, as embodying the immediate potentiality to 'self-develop' into such an absolute negation of bourgeois individuality). See, for instance, Shortall's derivation of a 'counter-dialectic of class struggle' – i.e. 'the potential class subjectivity of the working class' – that 'comes to delimit the functioning of the dialectic of capital', and whose foundation resides in the presupposition of the worker 'as both a free subject and as *non-capital*' (Shortall 1994, pp. 128–9, original emphasis). By contrast, as I have shown elsewhere, the solidaristic collective affirmation of that abstractly free subjectivity is but a more concrete realisation of the very same alienated content, hence, of the reproduction of capital (Starosta 2015, Chapter 7).

[12] For a more in-depth and extensive examination of these issues, see Starosta 2015.

[13] In contrast to my reading, Psychopedis (2005, pp. 80–1) sees in the implementation of legal norms to regulate the working day an immediate expression of the 'logic of revolution' already at work. Writing from a broadly understood '*Open Marxist*' perspective, Psychopedis grounds revolutionary subjectivity in the affirmation of a generic human materiality that exists in the mode of being denied, i.e. in an alienated social form. On this score, his argument does not substantially differ from that of Bonefeld discussed earlier in this article. However, Psychopedis gives the overall argument an idiosyncratic twist. In his own words, 'the dialectical presentation is not simply a matter of contrasting the "bad form" with the "good contents"' (Psychopedis 2005, p. 80). Instead, it is a matter of 'the demonstration that in capitalism the social forces of production become forces of destruction', so that 'this form poses a real threat to the continued existence of this materiality' (Ibid). The ground of the revolution is thereby seen as residing 'in the attempt of preserving the conditions of life' in the face of capitalism's destructive tendencies and the ultimately *unstable* character of the capitalist state's direct regulation of the material conditions of social reproduction, insofar as 'in the long run capital cannot tolerate regulations that reduce the profit margin' (Psychopedis 2005, p. 81). As compared to Bonefeld's approach, this train of thought has the merit of acknowledging that the foundation of revolution is not contained in the *simplest* contradiction between human content and reified form, but in a *more concrete determinate expression* of that contradiction. The further dialectical exposition of form-determinations beyond commodity fetishism thus becomes more meaningful for the discovery of the

---

social foundation of the emergence of the revolutionary subject. Nevertheless, Psychopedis still relapses into grounding revolutionary subjectivity in an element which is external to the contradictory self-movement of the capital form: revolution is seen as the affirmation of an abstractly self-determining struggle for society's survival in response to capital's destructive barbarism. Thus, the necessity of revolution is not *immanently* carried by the capital form; instead it is carried by the reproductive conditions of an abstractly conceived 'society' lacking in form-determinations, whose existence is 'thwarted' by its subsumption under the capital form. In the end, Psychopedis's account comes down to a more sophisticated version of Luxemburg's 'socialism or barbarism', i.e. of the classical Marxist view of socialism as the 'only salvation for humanity' in the face of 'war, famine and disease' (Luxemburg 1971, p. 367).

[14] Note, however, that Marx's respective presentations of this question in *Capital* and the *Grundrisse* differ in focus. While in the former text he rather one-sidedly unfolds this tendency for the production of universal productive subjects as it results from the increasing degradation of the wage-workers' particularistic dimension of their productive subjectivity, albeit meagerly offset by the compulsory elementary education clauses contained in the Factory Legislation (Marx 1976, pp. 545, 614-18), in the 1857-8 manuscript he offers a fuller picture of these determinations by also bringing to light the opposite movement of universalistic *scientific expansion* of human productive subjectivity which is entailed by the system of machinery (Marx 1993, pp. 699-700, 705-6, 709). In this sense, a systematic development of the grounds of revolutionary subjectivity in the real subsumption requires that both text be read together. For a more detailed treatment of this point, see Starosta (2015, Chapters 8 and 9).

On value and abstract labour: A reply to Werner Bonefeld

Axel Kicillof
University of Buenos Aires, Argentina – CONICET (National Council for
Scientific and Technological Research)

Guido Starosta
National University of Quilmes, Argentina

Abstract

This article offers a reply to Werner Bonefeld's recent contribution to the debate on value and abstract labour, in which he critically engages with our previous articles dealing with these questions. We argue that Bonefeld's criticisms are not simply based on disagreements over these controversial issues, but also on a misunderstanding of our stance on abstract labour and value. In addition to clarifying our position, the article provides some brief critical remarks on Bonefeld's own intervention in the debate and shows that his contribution fails to offer a solid analysis of the fundamental categories of the critique of political economy.

Keywords

value, abstract labour, materiality, social form

Werner Bonefeld has recently published an article in this journal (Bonefeld, 2010), in which he critically examines our contribution to the Marxian debates on the nature of abstract labour and value (Kicillof and Starosta, 2007a; Kicillof and Starosta, 2007b; Starosta, 2008). While we welcome the critical reactions that our articles have stimulated, we feel that Bonefeld's criticisms are not simply based on disagreements over these controversial issues, but also on a misunderstanding of our position on those more

abstract determinations of the capitalist mode of production. Since we believe that this misunderstanding has led Bonefeld to fail to reconstruct our argument accurately, we would like to use this short note to clarify our stance on abstract labour and value. Also, we shall offer some brief critical remarks on Bonefeld's own intervention in the debate. In this way, we shall argue that despite his claim to make explicit what is already implicit in Marx's treatment of abstract labour and value in *Capital* (Bonefeld, 2010: 261), he actually departs from the latter considerably. More importantly and regardless of 'what Marx really said', we show that Bonefeld's contribution fails to offer a solid analysis of the fundamental categories of the critique of political economy.

At the broadest possible level, Bonefeld rightly captures the essence of our argument: namely, we claim that while value is the simplest economic form specific to the capitalist mode of production, abstract labour (i.e. the former's social substance) is a material expenditure of human corporeality that bears no historical specificity (Bonefeld, 2010: 259, 270). However, beyond this very general point, which Bonefeld finds 'intriguing' (Bonefeld, 2010: 259), he misunderstands and/or misreads our position on several scores. Here, we shall mention only a few of them.

In the first place, he states that we 'see abstract labour as a transhistorical category that in capitalism is "represented" by the value-form' (Bonefeld, 2010: 259), when we state very clearly that it is *materialised* or *objectified* abstract labour that is socially represented in the form of value (or 'coagulates', in Marx's parlance. See Marx, 1976a: 142). This might seem an all-too-subtle difference, and therefore a minor issue. But this is precisely one of the central points on which, among other things, our critique of the circulationist view of labour as becoming abstract through the exchange of commodities against money rests (Kicillof and Starosta, 2007a: 20; Marx, 1976a: 152-3).

Second, Bonefeld misrepresents our careful textual reconstruction of Marx's dialectical presentation in the opening chapter of *Capital*. Where we state that Marx's initial discovery of abstract labour in the first few pages of Chapter 1 only brings out the physiological materiality of abstract labour without actually explaining why this productive expenditure of human corporeality in general objectifies in the historically-specific form of value (Starosta, 2008: 308), Bonefeld reads exactly the opposite: that 'the analytical reduction of value to its substance reveals only the capitalist representation of abstract labour – it does not tell us anything about its generic materiality' (Bonefeld, 2010: 260).[1] In addition, we explicitly argue that Marx's starting point is the commodity as the most abstract form of capital (thus a social form specific to the capitalist mode of production) (Kicillof and Starosta, 2007b: 16, Kicillof and Starosta, 2007a: 28) and that, as a consequence, his dialectical presentation consists in the 'ideal reproduction' of the 'immanent determinations' characterising this historical form of social wealth (Kicillof and Starosta, 2007a: 35; Starosta, 2008: 298). This should be done by taking 'the individual product in our hand and [analysing] the formal determinants that it contains as a commodity and which stamp it as a commodity' (Marx, 1976b: 1059). And yet, according to Bonefeld, we state that 'before developing the capitalist categories, Marx first sought to "discover" their generic material presupposition' (Bonefeld, 2010: 260).[2]

Third, we are said to postulate that 'class struggle rests on and develops the fundamental contradiction between transhistorically conceived materiality and social form' (Bonefeld, 2010: 261). Bonefeld seems to have in mind here the contradictory existence of abstract labour as a generic material determination which in capitalism acquires a historically-specific social determination as substance of the most general social relation, namely, value (Bonefeld, 2010: 258). In other words, he appears to be suggesting that we consider the class struggle as the unmediated expression of this latter contradiction of the capitalist mode of production (Bonefeld, 2010: 269). But, on the one hand, we argue that the essential immanent contradiction of capitalism is between its *historically specific materiality* and its social form. This is why we highlight capital's inner *tendency* for the development of the *universality* of productive subjectivity, which only this mode of production brings about, and only on the basis of previously achieved historical presuppositions (Kicillof and Starosta, 2007a: 39; Kicillof and Starosta, 2007b: 30; Starosta, 2011; Marx, 1993: 162). This entails a historically specific socialisation and universalisation of the *concrete character of labour*. In this strict sense, the materiality of abstract labour is of no immediate relevance to our argument. And far from endorsing positivist notions of progress (Bonefeld, 2010: 272), we explicitly note the alienated character of this historical process and the material mutilation of their productive subjectivity that workers suffer due to the inverted existence of their social being as an attribute of dead labour (Kicillof and Starosta, 2007a: 37). On the other hand, the whole gist of our critique of De Angelis revolves around the historicity of class struggle as a specifically capitalist social form. More precisely, against its widespread 'ontologisation' in many Marxist currents, we see the class struggle as the most general collective *direct* social relation through which the *indirect* unity of social labour through the commodity form asserts itself (Kicillof and Starosta, 2007b: 28). In other words, in our approach the foundation of the class struggle is socially mediated through and through, and has nothing to do with an abstract, unmediated contradiction between transhistorical materiality and social form, as Bonefeld believes.

Finally and more importantly, Bonefeld further claims that we consider that 'the transhistorical materiality of abstract labour obtains through specific historical forms' (Bonefeld, 2010: 272: 259), presumably because, in his (mis)reading, we allegedly argue that 'abstract labour is the material foundation of the human metabolism with nature' (Bonefeld, 2010: 259). Against this, we actually state that it is labour in its material unity as conscious productive activity (which always has a two-fold material character, abstract and concrete), that constitutes the specifically human form of the life process, i.e. the human species-being (Kicillof and Starosta, 2007a: 19-20). As for abstract labour and its 'historically changing social forms', we are absolutely emphatic and unequivocal that, despite its character as a generic material determination of labour, its role as mediator in the establishment of the unity of the social character of productive activity is uniquely capitalist (Kicillof and Starosta, 2007b: 16). Since this is probably the main source of Bonefeld's confusion over our position, we shall say a few more words on this crucial point.

Perhaps the single most important point that we tried to make in our articles in this regard is that the contemporary view of abstract labour as the specifically capitalist form of labour, downplays, or simply obliterates, the actual historical character of value-producing labour. This historical specificity, we argued, lies in the *private and independent* form taken by social labour (or private labour for short). Our contributions therefore were not simply a case for the generic material nature of abstract labour but, more fundamentally, an attempt to restore the centrality of private labour in the debate over the determinations of the value-form.[3] In order to bring out this historical specificity and the determination of abstract labour in it more clearly, let us first examine the case of non-capitalist societies.

All those 'first social forms' that precede capitalism (whether patriarchal, ancient or feudal) were based on direct personal relations in production (Marx, 1993: 156), in which the process of social reproduction was established through the 'natural or political super- and subordination of individuals to one another' (Marx, 1993: 159). Although all individual labour also had a social character in those societies, the material unity of the process of human metabolism as a whole was consciously organised before production actually took place and, therefore, 'it was the distinct labour of the individual in its original form, the particular features of his labour and not its universal aspect that formed the social ties at that time' (Marx, 1987: 275). In other words, it was the *concrete* character of labour, its particularity, which directly or immediately realised the establishment of the material unity of the social division of labour (Marx, 1976a: 170). This does not mean that abstract labour, as the universal or general aspect of the materiality of the labour of the individual (i.e. the expenditure of brains, nerves, muscles, etc., regardless of its particular form), did not exist or had no reality. But it did not act as the social form of individual labour and, consequently, its materialisation in the product (its existence not as 'motion' but as 'rest' – see Marx, 1993: 143) did not have to be socially represented in the form of value or in any other social form whatsoever. When social labour is consciously organised through direct social relations, 'there is no need for labour and its products to assume a fantastic form different from their reality' (Marx, 1976a: 170). This is why Bonefeld cannot find any reference to other historical forms of social representation of abstract labour in our papers other than the capitalist form (Bonefeld, 2010: 259). To put it in plain English, it follows from our approach that there are no other historically specific social forms of representation of (congealed) abstract labour. And note that, in opposition to what Bonefeld believes we think, this applies to communist society as well. As the fully conscious organisation of the social life-process by the thereby free individuality of universally developed individuals (Marx, 1993: 158), communist society will not mediate the establishment of the unity of social labour on the basis of the abstract or general materiality of individual labour (i.e. of abstract labour). As much as the first social forms based on relations of personal dependence, the communist stage of development of the human species-being will establish the social character of labour on the basis of its concrete character. Communism consequently does not entail the affirmation of the abstract character of labour as social mediator beyond its capitalist integument. It involves the abolition both of value and of the alienated social determination of abstract labour as substance of that objectified form of social mediation. *Contra* Bonefeld, however, it does not and cannot conceivably entail the abolition of the abstract character of labour either, whose material determination as universal aspect underlying the varied useful kinds of labour remains a 'physiological fact' (Marx, 1976a: 165). The object of revolutionary action is not the overcoming of abstract labour but of private labour, through the conscious production of the direct association of the thereby truly free individuals.

Let us now return to the private character of labour that defines the historical specificity of the capitalist mode of existence of human productive activity. This mode of production 'presupposes the dissolution of all fixed personal (historic) relations of dependence in production, as well as the all-sided dependence of the producers on one another' (Marx, 1993: 156). This means that at the very moment when the human individual has to set into motion the expenditure of her productive subjectivity in a particular concrete form, the only remaining social nexus among the private producers is that each of them embodies an aliquot part of the total labour power of society (Iñigo Carrera, 2007: 51). As Marx puts it in the section on the fetishism of the commodity, 'from this moment on, the labour of the individual producer acquires a twofold social character' (Marx 1976a: 166).[4] As in any other mode of production, she has to expend her productive subjectivity in a socially useful form. However, she has no manifest direct social relations that could tell her how to articulate the exertion of the individual labour power that she embodies with the needs of the rest of society. The material unity of the social division of labour is thus manifested indirectly through the determination of the products of labour as generally exchangeable things, i.e. as bearers of value. But as we argued at length in our articles (Kicillof and Starosta, 2007a: 22), this *social* equivalence of different use-values as commodities can only be premised on the *material* identity of the varied useful labours as a physiological expenditure of human labour power in general, that is, 'as labour whose materiality as the expenditure of human labour power has not yet assumed a specific concrete form' (Iñigo Carrera, forthcoming). The private labour of the commodity producer thereby acquires a second, historically specific social character that must mediate the affirmation of the first sense of labour's sociality discussed above. Its material or physiological aspect as human labour in general (i.e. as abstract labour) has to socially relate the varied privately undertaken labours by 'congealing' in the form of the 'ghostly' objectivity of value (Marx, 1976a: 166). But in doing so, abstract labour does not abstractly negate its generic material nature; instead, it gives this materiality a unique social determination in the establishment of the unity of social labour. To put it differently, abstract labour as such cannot be simply identified with value-producing labour. The latter actually is *privately performed (socially necessary) abstract labour*. The following passage from Marx's section on the form of value (hardly a Ricardian one!), nicely and succinctly captures this twofold determination of abstract labour in capitalist society (material/generic and social/historically specific):

> The innumerable equations of which the general form of value is composed equate the labour realized in the linen with the labour contained in every other commodity in turn, and they thus convert weaving into the general form of appearance of undifferentiated human labour. In this manner the labour objectified in the values of commodities is not just presented negatively, as labour in which abstraction is made from all the concrete forms and useful properties of actual work. Its own positive nature is explicitly brought out, namely, the fact that it is the reduction of all kinds of actual labour to their common character of being human labour in general, of being the expenditure of human labour-power.
>
> The general value-form, in which all the products of labour are presented as mere congealed quantities of undifferentiated human labour, shows by its very structure that it is the social expression of the world of commodities. In this way it is made plain that within this world the general human character of labour forms its specific social character (Marx 1976a, 159-60).[5]

Bonefeld on value and abstract labour

Methodologically, Bonefeld's perspective on abstract labour can be inscribed within the broad tradition initiated by Rubin, which we have already extensively critiqued in an earlier article (Kicillof and Starosta, 2007a: 16 and ff.). Briefly put, through an axiomatic declaration of principles that stated that 'political economy does not analyse the material-technical aspect of the capitalist process of production, but its social form' (Rubin, 1973: 1-2), Rubin dogmatically ruled out from the outset all possible material character in the determination of abstract labour. As we have argued, the result was the formalist substitution of a 'sociological theory of abstract labour' for Marx's analysis of the commodity. Along the same lines, Bonefeld adopts an idiosyncratic 'social form-analytical' approach that, by definition, 'says that capitalist economic categories do not have a transhistorical validity' (Bonefeld, 2010: 263). And also like Rubin and in opposition to Marx, he 'applies' this approach to the 'concept' of abstract labour instead of starting out 'from the simplest social form in which the labour-product is presented in contemporary society' (Marx, 1975: 198) and seeing what the analysis of this 'concretum', the commodity, tells us about its own immanent determinations (including abstract labour among them). In this way, Bonefeld unsurprisingly concludes what he already knew from the beginning on the basis of his general methodological principles: namely, that 'abstract labour is a specific capitalist form of labour' and that to claim otherwise inevitably ends up naturalising capitalist economic categories (Bonefeld, 2010: 259). Again like Rubin, he assumes that in order to secure his conclusion he needs to deprive abstract labour of all generic materiality.[6]

Bonefeld, however, admits that our reading of *Capital* is on strong textual grounds, but seems to attribute this strength to an alleged ambiguity on Marx's part in the treatment of abstract labour. According to Bonefeld, 'he defines it in asocial physiological terms, and insists that it is a specifically capitalist form of labour' (Bonefeld, 2010: 258).[7] But rather than being ambiguous, the logic of his argument should lead him to claim that Marx's treatment of abstract labour is definitely and simply *wrong*. In effect, in the section on the twofold character of labour, Marx states that 'if we leave aside the determinate quality of productive activity, and therefore the useful character of the labour, what remains is its *quality* of being expenditure of human labour-power (…) a productive expenditure of human brains, muscles, nerves, hands, etc.' (Marx, 1976a: 134, emphasis added).[8] The originality of Bonefeld's contribution lies precisely in the rejection of the validity of this initial analytical move in which Marx discovers the abstract or universal aspect of the materiality of human labour by abstracting from its concrete particularity.[9] Whereas most Marx scholars who see abstract labour as historically specific would not deny this 'physiological fact', but would argue that this is not the correct 'concept' of abstract labour as substance of value (and some would also claim that Marx tended to confuse the two), *Bonefeld directly denies the reality of a material identity among the various kinds of useful concrete labours, irrespective of the problem of the connection between this 'physiological' abstract labour and value-production.*[10] For Bonefeld, 'in (material) reality' there is only concrete labour; the physiological identity between different useful labours has no materiality, hence no reality.

> The real existence of labour is always concrete. Every physiological expenditure of labour is expenditure of concrete labour. That is, physiological expenditure of labour entails a specific productive application, and is thus concrete. Muscles do not burn sugar in the abstract. *Labour is concrete labour, not labour in the abstract.* (Bonefeld, 2010: 266)[11]

This outright rejection of the reality of the physiological determination of abstract labour leads Bonefeld to challenge Marx's discovery of a material identity between the various kinds of useful labours as sheer expenditures of human labour power. Instead, he argues that 'if we abstract from the useful labour expended on a product, we do not discover the so-called "generic materiality" of abstract labour. What we find is matter, something for use, furnished by Nature' (Bonefeld, 2010: 264).[12] But if this is so, how is it possible for different commodities to establish an exchange relation given that, as Bonefeld rightly claims, 'exchange cannot take place without equality, and equality not without commensurability' (Bonefeld, 2010: 265)? Since in his view, this commensurability cannot be grounded on the universal material determination of all human labour, he must of necessity conclude that that this equality is 'socially imposed' on irreducibly diverse concrete labours. This social imposition, his argument goes, is actually the subsumption of the variety of human activities to 'abstract time' (Bonefeld, 2010: 262).

According to Bonefeld, the reality of abstract labour and its objectification is not the premise of the exchange of use values as commodities (i.e. as material bearers of value), but rather is in the first place 'forcibly brought about by exchange' (Bonefeld, 2010: 264). This abstraction then 'projects the ghost of value that achieves validity in the form of money, back into production (…) that sucks living labour dry, reducing it to a "time's carcass"' (Bonefeld, 2010: 266). In so far as products are exchanged, concrete labours come to be considered as labour in motion that is in turn measured by labour time, 'a time of abstract, constant, and equal time units, measured by clock time', an 'homogeneous and empty time' (Bonefeld, 2010: 268). In other words, the 'abstraction' that socially forces the equalisation of otherwise irreducibly unequal human labours is their subjection to the same economy of time, so that 'the expenditure of labour does not occur in its own good time. It occurs within time – a time made abstract, and imposing' (Bonefeld, 2010: 267). Thus, in this view the different private labours are not socially related as equal on the basis of their existing material equality as expenditures of human labour power regardless of its form. Rather, their equality is forcibly imposed upon their irreducible material heterogeneity through their social reduction to an embodiment of abstract time. Strictly speaking, then, it is not first and foremost labour that becomes abstract but, more fundamentally, the time that measures concrete labours (the abstraction of labour being derivative of this according to Bonefeld's train of thought).[13]

This theoretical construction definitely parts company with the analysis of the commodity made by Marx, who after discovering the abstract character of labour as the substance of value asks, 'How, then, is the magnitude of this value to be measured? By means of the quantity of the "value-forming substance", the labour, contained in the article. This quantity is measured by its duration, and the labour-time is itself measured on the particular scale of hours, days, etc.' (Marx, 1976a: 129). In other words, (socially necessary) labour-time determines the *magnitude* of value or constitutes value's *quantitative* determination. But the abstract character of (privately-undertaken) labour constitutes the substance of value and therefore constitutes its *qualitative* determination.

Moreover, as the quote from Chapter 1 reproduced in the previous section makes clear, abstract labour plays that part in the qualitative determinacy of value not simply as abstraction from concrete particularity, but in its 'positive nature' or *quality* as expenditure of labour power in general. In brief, whereas Marx in *Capital* clearly distinguishes between the qualitative and the quantitative determination of value, Bonefeld conflates them and actually converts the determinant of the magnitude of value into its qualitative content. Thus he approvingly quotes Bensaid's confused view that 'time appears simultaneously as measure of value and as its substance' (Bensaid 2002: 80, cited in Bonefeld, 2010: 267). Very much like Rubin's contribution, Bonefeld's approach suffers from a conceptual collapse or amalgamation of categories, not only value and abstract labour, but also their qualitative and quantitative determinacy.[14]

Still, Bonefeld's contribution cannot be simply read as a reinstatement of Rubin's position. In fact, he recognises limitations in Rubin's circulationist strand of thought (Bonfeld, 2010: 274). Thus, he tries to reconcile some of the insights found in the circulationist approach with a perspective that gives the sphere of production its due place in the determination of the value-form. He partly draws on the works of Chris Arthur and of Riccardo Bellofiore, but also takes insights from De Angelis's view of abstract labour as imposed work and therefore a concrete form of the class struggle (Bonefeld, 2010: 267). We have offered an in-depth critical assessment of the latter perspective in an earlier article in this journal, so we will not repeat our arguments here. Bonefeld, however, does not engage with our detailed critique of the idea of abstract labour as a mode of existence of the class struggle.

More importantly, Bonefeld's argument on abstract labour is either circular or incomplete. Thus, he grounds the abstract character of labour as activity in the projection of the ghost of value 'forcibly brought about by exchange' (i.e. the form of general exchangeability of commodities) back into production. But this begs the question of how different use-values can become formally identical, and thereby establish an exchange relation in the first place. Surely not on the basis of their identity as materialisations of abstract labour, since, according to Bonefeld, the latter is explained by the exchange relation itself. As we argued in our critique of Rubin and his contemporary 'circulationist' followers, to postulate that commodities are equal because they exchange and that they exchange because they are equal involves a logically fallacious reasoning. Alternatively, he would have to ground the abstract character of labour in a further social form taken by social labour, but this analytical step is missing from Bonefeld's account, thereby rendering his explanation incomplete.

Endnotes

1. On this specific point, Bonefeld completely glosses over the relevant methodological distinction between the analytic and synthetic phases of the dialectical exposition that is more fully developed in Starosta (2008).
2. This obviously does not preclude the possibility that the dialectical analysis of the commodity encounters more abstract determinations that pertain to the social production process in general, and are therefore not specific to capitalist society. However, two methodological points are in order. First, these more general determinations are not discovered as external presuppositions of the concrete social form under investigation, but as an aspect of its immanent content. This means that they are not discovered by finding the common elements

between capitalism and other modes of production (and here Marx's methodological remarks on 'production in general' in the 1857 Introduction are insufficiently dialectical, or at least not rigorous enough). Instead, they are discovered by searching 'within' the singularity of the individual commodity as the simplest economic 'concretum' of capitalist society (Marx, 1975: 199). Following from this, the judgement about the validity or relevance of these more abstract determinations should not be the result of the application of general methodological principles, whether 'historical materialist' or 'form-analytical'. Dialectical analysis must proceed by 'reflecting in ideas the life of the subject-matter' (Marx, 1976a: 102) without any methodological prejudice.

3. It also aimed at emphasising the materiality of private labour as a historic form of development of human productive subjectivity. Bonefeld overlooks these other, more important aspects of our intervention in the debate. In fact, the private character of labour is mentioned only once in Bonefeld's article and, furthermore, in a rather confused (if not incoherent) formulation: 'The peculiar social character of labour in capitalism comprises the existence of private labour as "directly social in its character"' (Bonefeld, 2010: 263). The essence of the private character of labour is precisely the indirect nature of its immanent social character!
4. This means that the negation of the individuality of the human subject implied in her reduction to mere bearer of an aliquot portion of the total social labour power emphasised by Bonefeld is a historically specific determination. However, it does not follow from this that it is not the individual material expenditure of human corporeality that produces value, as he further concludes. It only means that, from the perspective of value-production, the only exertion of individual labour power that matters is that which is socially necessary (Kicillof and Starosta, 2007a: 32; Marx, 1976a: 129; Marx 1986, 274).
5. As we shall see below, Bonefeld evidently reduces abstract labour to its 'negative' determination as 'abstraction from the concrete character of labour' and wholly misses its own 'positive' nature.
6. One possible source of Bonefeld's misunderstanding of our position is that he seems to be projecting his own formalistic method onto our substantive argument. Thus, he sees our approach as a mirror image of his own: all categories should be treated as a unity of an invariant generic material content and a historically specific social form. At this stage of our argument, it should be clear that nothing could be farther from our method.
7. Unfortunately, we are afraid that we cannot return Bonefeld's complimentary comment on the textual strength of our reading of Marx's *Capital*. The textual evidence supporting his claim that Marx insists that abstract labour is a specifically capitalist form of social labour is rather weak. In fact, like Rubin he tends to conflate value and abstract labour (simply assuming on the basis of general methodological principles that if value is specific so must be its substance, which is precisely what he should actually demonstrate). He then takes passages in which Marx is referring to value and 'applies' them to abstract labour. For instance:

   > 'Marx conceives of abstract labour as a "purely social reality" that can only appear in the social relations of "commodity to commodity" (Marx, 1983: 54)'. (Bonefeld, 2010: 259)

   The text that Bonefeld is paraphrasing is from the second paragraph of section three of Chapter 1, 'The form of value or exchange-value', but a cursory reading suffices to see that Marx is unequivocally referring to value as having a purely social reality and not to abstract labour.
8. The reason for the emphasis in 'quality' will become clear below.
9. The full grounding or actual explanation of this initial analytic discovery (the 'why' rather than the 'what') occurs only later in Marx's presentation, in the synthetic phase of the dialectical exposition in chapter one that starts in Section 3 'The form of value or exchange-value'. On this, see Starosta (2008).

10. Cf. Rubin and his tripartite division of the concept of labour into ‘physiological labour’, ‘socially-equalised labour’ and ‘abstract labour’. Similarly, Murray (2000) distinguishes between the general concept of abstract labour and the capital-specific ‘practically-abstract labour’. As we have argued in relation to Rubin, the introduction of additional categories obscures rather than sheds light on the inner connection between materiality and social determination of abstract labour in capitalism (Kicillof and Starosta, 2007a: 23). Be that as it may, note that even authors on whom Bonefeld relies heavily do not seem to deny the reality of the physiological determination of abstract labour. They just do not consider that that is the relevant concept as the substance of value. Thus, Heinrich dismisses the physiological definition because it is a ‘mental abstraction, in which at any rate any labour can be subsumed, irrespective of whether it is commodity-producing or not’ (Heinrich, 2008). However, he does not seem to question the reality of the physiological determination.
11. Bonefeld seems to be offering a peculiar reason for his rejection of the reality of a material identity between different kinds of labour (i.e. of ‘physiological’ abstract labour), namely: it cannot be apprehended through sensuous perception. ‘Abstract labour is not a substance that one can touch, see, smell or eat’ (Bonefeld, 2010: 266).

    Unless we are missing something, this statement relapses into the crudest kind of empiricism, which seems strange coming from someone who has made interesting and sophisticated methodological contributions to dialectical thought (see, for instance, Bonefeld, 1992). The fact that a certain determination is only accessible to us by means of thought or what Marx calls the ‘power of abstraction’ (i.e. by means of the specific attribute that sets our species-being apart from other life-forms) does not deny its materiality. No one can touch, see, smell or eat gravity. And yet it is obviously a real material determination of all bodies, as anyone jumping out of the window can tell.
12. We have to confess that we are simply perplexed by Bonefeld’s denial of the reality of the underlying universal material identity between different useful labours. For us, and Marx seemed to believed this as well, it is just a self-evident fact. We are afraid we cannot even find ways of engaging with that view.
13. In our view, there is nothing historically-specific about ‘abstract’ time per se. Time is a *quantitative* differentiation of nature in which therefore *quality* is sublated (see Hegel, 1999: 189, although as usual he inverts the real determination into a category of ‘pure thought’ which is then repeated in an external form in nature). In this sense, time is always ‘abstract’ if by this we mean indifference to quality. As Marx notes in the passage that Bonefeld quotes, this temporal dimension of nature exists in human activity as well: ‘Just as motion is measured by time, so is labour by *labour time*’, which is ‘the living quantitative aspect of labour as well as its inherent measure’ (Marx, 1986: 272). What Bonefeld describes as ‘abstract time’ is actually a concrete *expression* of the alienated relation of human beings to the materiality of their own life-activity entailed by value-production. And this obviously includes its temporality. But it is not the *ground* of the value-producing character of labour.
14. Before *Capital*, Marx himself had not fully established the ‘positive material nature’ of abstract labour as expenditure of labour power in general. That is why it is possible to find several occasions on which he uses formulations that conflate qualitative and quantitative determinacy of value and abstract labour, especially in the *Grundrisse* but even as late as the 1859 *Contribution*. On this, see Iñigo Carrera (forthcoming). Bonefeld himself acknowledges that there is a potential tension in the way he handles qualitative and quantitative moments of the determination of value, but does not see this as a problem since ‘there is no substance without measure’ (Bonefeld, 2010: 273 fn. 12). This is true enough, but that is precisely the reason why his sheer dissolution of qualitative determination into quantitative determination of value is problematic: he is postulating a ‘measure without a substance’, that is, without a quality whose magnitude is being measured.

The Commodity Nature of Labor-Power

GUIDO STAROSTA and GASTÓN CALIGARIS

ABSTRACT: Some recent Marxist contributions, among them the so-called New Solution to the "transformation problem," call into question the idea of labor-power as a fully-fledged commodity. Yet, the rejection of the commodity nature of labor-power compromises Marx's whole explanation of the origin of surplus-value on the basis of the exchange of equivalents. It can be shown, however, that it is possible to offer a positive case for the commodity-nature of labor-power which is consistent with Marx's broader dialectical investigation of the determinations of the value-form. This requires building upon the arguments that Marx explicitly put forward in his economic works, but also going beyond them, albeit on the basis of those arguments themselves. Furthermore, this novel approach that treats the reproduction of labor-power as a commodity determined by the self-valorization of capital proves to be very valuable in shedding light on two classic Marxist controversies, namely: the debate on domestic labor and the one on skilled labor.

Introduction

IN A LETTER TO BECKER from April 17, 1867, Marx referred to *Capital* as "without question the most terrible MISSILE that has yet been hurled at the heads of the bourgeoisie (landowners included)" (Marx, 1987a, 358). Unfortunately, in the rest of that brief note Marx does not clarify the specific sense in which he considered his work to be such a "terrible missile" against the bourgeoisie. However, it seems quite safe to assume that his scientific explanation of the source of capitalist "profit" in the exploitation of wage-workers was among those fundamental aspects of the critique of political economy that he had in mind. As is widely known, the key to this explanation resides in the discovery of the existence of a commodity "whose use-value possesses the peculiar property of being a source of value" (Marx, 1976a, 270). This commodity is, of course, labor-power which, "like all other commodities . . . has a value" (Marx, 1976a, 274).

Now, in light of this centrality of the commodity nature of labor-power for Marx's critical investigation of the nature of the capital relation, its rejection can only amount to turning that "terrible missile" against Marx himself. In effect, once we reject the commodity nature of labor-power, then Marx's whole explanation of the origin of surplus-value on the basis of the exchange of equivalents falls down. As Krätke comments while revisiting the very early critiques of Marx's "unsolved puzzles" in the theory of wages, the "corollary" of such a rejection of the proposition that labor-power is a commodity and has a value "like all other commodities" is "clear and devastating" (Krätke, 2009, 166). Yet, this objection to the commodity nature of labor-power has resurfaced in the last couple of decades. Curiously enough, it has not been advanced by Marx's "detractors" but, as we discuss below, by some of his followers.

A first aim of this article is to critically engage with some of these recent Marxist contributions which, whether they see it as a rectification or ratification of Marx's argument in *Capital*, call into question the idea of labor-power as a fully-fledged commodity. This is done in the next section, where we review some of the main positions in this contemporary debate. In addition, we subsequently offer a positive case for the commodity-nature of labor-power that builds upon, but also goes beyond, the arguments that Marx explicitly put forward in his economic works. Finally, in order to illustrate the usefulness of this novel take on the determinations of the commodity labor-power, we revisit two classic Marxist controversies that are intimately connected with the central subject matter of this paper, namely: the debate on domestic labor and the one on skilled labor.

Marxist Controversies over Labor-Power as a Commodity

The objection to the commodity nature of labor-power and, *a fortiori*, to the determination of its value by the socially necessary labor-time required for its production, can be traced back to the whole series of critiques of Marx that emerged as soon as Volume III of *Capital* was published.[1]

---

[1] As argued elsewhere (Kicillof and Starosta, 2007a), in its simplest determination *privately undertaken* labor is socially necessary (hence value-producing) if it satisfies two conditions: first, it corresponds to the technologically normal conditions of production prevailing in

Thus, already in 1907 Bortkiewicz argued that since there is no "competition between producers" of this commodity, wages cannot be subordinated to "the general law of value" and therefore its value cannot be determined in the same way as the value of other commodities (Bortkiewicz, 1952, 57). Strictly speaking, this first line of criticism mainly and explicitly revolved around the denial of the existence of an adjustment process of the price of labor-power to the average socially necessary labor-time for the production of this particular commodity. However, insofar as in Bortkiewicz's Ricardian approach there was no clear distinction between the price and the value of labor-power, the implausibility of such an adjustment mechanism implicitly called into question the very foundations of the value-content of labor-power. In fact, Bortkiewicz concluded that real wages had to be taken as fixed (Bortkiewicz, 1952, 57). According to Krätke, Tugan-Baranowsky went even further and argued that "labor power was not a commodity at all, wages could not be considered a 'value phenomenon' and Marx's theory of wages was outright wrong or just tautological" (Krätke, 2009, 169). Yet, as Krätke also reports, Marxists at that time did not respond to the challenge (Krätke, 2009, 166).

Although similar arguments emerged later in the 20th century, and on this occasion among scholars who were otherwise sympathetic to Marx's ideas (*e.g.*, Castoriadis, 1988; Bowles and Gintis, 1981), it has been in relatively recent times that the objection cropped up within the specialized Marxist literature. Moreover, in many cases the objection to the commodity nature of labor is not seen just as a correction to an allegedly inadequate treatment of the subject by Marx, but is even presented as a reflection of Marx's own views.

This rejection of the commodity nature of labor-power and, consequently, of Marx's account of the determination of its value, has come from rather disparate traditions. The so-called systematic dialectics strand of value-form theory is a case in point. Thus, Chris Arthur takes "distance from Marx's attempt to treat labor power as a produced commodity subject to the law of value" (Arthur, 2006, 90). More specifically, he states that "wage-labor should be treated in the same way as landed property, namely as a material presupposition of

---

society (Marx, 1976a, 129), and, second, it can satisfy a *social* need (Marx, 1976a, 131), regardless of whether that need arises from "the stomach or the imagination" (Marx, 1976a, 125). In other words, only under those two circumstances is the objectification of the abstract character of private labor socially represented in the form of value.

capitalist production, which is rewarded with part of the value created in production, namely the wage" (Arthur, 2006, 90; see also Reuten and Williams, 1989, 68; and Roblez Baez, 2011, 26–27n).

Still, the most remarkable case is that of the so-called "New Solution" or "New Interpretation" to the "transformation problem" (Foley, 1982; Lipietz, 1982; Dumenil, 1983). In effect, unlike the rather incidental role played by the rejection of labor-power as a "genuine commodity" among "new dialecticians," for these other scholars it constitutes one of the pillars on which their whole theoretical construction is based. On the other hand, their arguments have already been critically examined quite sharply by other Marxist scholars (Mavroudeas, 2001; Fine *et al.*, 2002), which provides us with a firmer basis to develop our own arguments.

Perhaps the clearest formulation of the New Solution's corollary about the commodity nature of labor-power can be found in the work of Simon Mohun. According to this author, labor-power

> is not a produced commodity in the same sense [as other commodities]. It is a capacity or potentiality of people, and people are not (re)produced under capitalist relations of production. No capitalist production process is involved, no process of adding value to the means of production by living labor; neither do there exist different technologies of production in competition with one another which must be averaged to find a market value. (Mohun, 1994, 398.)

For this reason, Mohun continues, Marx's own definition of the value of labor-power is not given in terms of the labor-time required for its production but "in terms of the value of the commodities which the money-value of labor-power can purchase, or command" (Mohun, 1994, 398). It is this novel conception of the value of labor-power that provides one of the keys to this approach's specific solution to the "transformation problem." In effect, under this new definition, the value of labor-power is determined as the part of total value-added represented by the wage share. However, through an idiosyncratic formal procedure, they still conclude, in a roundabout way, that the money-wage represents a determinate quantity of socially necessary abstract labor.

The first step in the New Solution's construction is to posit an "immediate equality between the total price of the net product and the total living labor performed in each period" (Mavroudeas, 2001, 59). On this basis, these authors subsequently obtain the "monetary expression of labor" (MEL) as the ratio between the total price of the net product and the total hours worked. The MEL thereby allows them to transform money-prices into "labor-values." In the case of labor-power, its "value" expressed in "labor-time" is calculated by multiplying the rate of money-wages by the MEL. Through this peculiar procedure, these scholars consider that they avoid the problem of transforming variable capital and, as a consequence, that they offer a way to sidetrack the divergence between total profits and total surplus value. However, this "solution" to the "transformation problem" comes at the cost of parting company with Marx's own definition of the value of labor-power as determined by "a definite quantity of the average social labor objectified in it" (Marx, 1976a, 274). As Foley puts it in his seminal contribution to the New Solution, "the value of labor power, in this perspective, is the fraction of the total abstract social labor time claimed by workers in the form of the wage" (Foley, 1982, 42; see also Mohun, 1994, 403). Although not all supporters of the New Solution explicitly draw the conclusion that this entails the rejection of the commodity nature of labor-power, we will see below that this is the necessary implication of this approach.

As mentioned above, this conception of the value of labor-power has been strongly criticized by other Marxist scholars. In our view, Mavroudeas' (2001) critique stands out as probably the sharpest and most illuminating. According to this author, there are several shortcomings in the New Solution approach. In the first place, this approach violently abstracts from the intermediate steps that lead from socially necessary labor for the reproduction of workers to the value of labor-power. Specifically, it "discards the intermediation of a set of use-values (and their value) between necessary labor-time and money-wages and proceeds to link them directly" (Mavroudeas, 2001, 59). The upshot of this is that the "New Solution's conception of the value of labor-power ends up with a Smithian labor-commanded conception of value rather than one based on abstract labor" (Mavroudeas, 2001, 59). In turn, this has the consequence of grounding the quantitative determination of the value of labor-power in extra-economic factors which, "when this is supplemented with the rejection of the commodity-nature of labor-power, then it can easily lead to a prioritization of power relations independently and almost prior to socio-economic relations" (Mavroudeas, 2001, 55). In effect, regardless of the New Solution's claim that in their conception the value of labor-power still represents a share of the total abstract labor performed, it is self-evident that a "value" that is not the objectification of the social determinations of the material production process of the commodity that acts as its "bearer," can hardly be taken as synonymous with what Marx termed the "value of a commodity." Thus, the New Solution's eventual rejection of the commodity nature of labor-power is the other side of the same coin of their idiosyncratic conception of the determination of its value.

However, as Saad-Filho argues, despite the weaknesses of the New Solution, it is not easy to find a solid alternative within the Marxist literature (Saad-Filho, 2002, 48 ff). Most other contributions relapse into an equally problematic Ricardian or "labor-embodied" approach. At its most extreme, this perspective tends to assume an immediate identity between the value of labor-power and a "fixed" bundle of means of subsistence. But even in its more nuanced versions, this conception does not seem able to account for the determination of the composition of those "wage-goods," their historical changes or the wage differential among different segments of the working class (Fine, 1988, 180). Moreover, this Ricardian approach eventually ends up reifying workers, as if they were "slaves, beasts of burden [or] machines" (Saad-Filho, 2002, 48) and, as a consequence, renders arbitrary the very concept of "exploitation" (Fine *et al.*, 2002, 11).

In order to overcome the limitations of both the New Solution and neo-Ricardianism, Fine *et al.* come up with a third alternative whose main thrust is that "the value of labor power is neither a quantity of money nor goods but a quantity of value" which, in turn, is determined "at the aggregate level through the exchange between capital and labor as a whole (*i.e.*, as social classes), prior to the process of production" (2002, 12). Now, although it is correct that the value of labor-power is already determined prior to the process of production which follows the capitalist's purchase of that "peculiar commodity," this analysis does not take us very far from a mere repetition of what Marx explicitly wrote in *Capital*. In other words, this position amounts to just *asserting* the connection between the value of labor-power and the value of means of subsistence without *demonstrating* it. No actual explanation of that relationship is offered other than the invocation of Marx's texts. Maybe aware of this, these authors state that a proper full explanation of the value of labor-power needs to reconsider it at more complex levels of analysis. For instance, this requires the dynamic redefinition of the bundle of wage-goods resulting from the development of the productive powers of labor. Indeed, the accumulation of capital "tends both to redefine (lower) the value of labor power and (increase) the wage bundle" (Fine *et al.*, 2002, 12). Furthermore, "consumption norms" vary greatly across the different categories of workers, so that it makes no sense to posit an "average" consumption bundle which would determine the value of labor-power "in general" (Fine *et al.*, 2002, 12).

It seems to us that this alternative position does not succeed at fully overcoming the weaknesses of its opponents. First and foremost, these authors do not actually offer a clear and precise explanation of the determination of the value of labor-power "in general." Instead, they just sidetrack the problem by invoking the need to incorporate more complex phenomena. Furthermore, methodologically speaking, it is quite simply incorrect to argue for the impossibility to fully resolve the question of the value of labor-power "in general" given the complexity of its concrete forms of realization. It is not only possible but necessary to treat and settle the question at the level of the simpler or more abstract determinations of capital.[2] In fact, Marx himself made this methodological point in the *Economic Manuscripts of 1861–1863* when justifying the initial abstraction from the determinants of the value of labor-power attributable to its complexity, since

> important as the latter consideration becomes when it is a matter of analysing the differing values of individual branches of labour, here it is irrelevant, for we are only concerned with the general relationship between capital and labour, and therefore have in view ordinary, average labour, seeing all labour as only a multiple of this average labour, the training costs of which are infinitesimally small. (Marx, 1988, 43.)

---

[2] In this sense, the issue under discussion in this paper pertains to the "level of abstraction" of Volume I (*i.e.*, to the social form of the process of production), and is analytically separable from the concrete forms assumed by the establishment of the unity of the movement of the total social capital in circulation (*i.e.*, the "level of abstraction" of Volume III, including the so-called "transformation problem"). In other words, this is a problem pertaining to value-*production* and not to its *distribution*. However, one implication of our argument is clear in this regard. If one concludes that labor-power is a fully-fledged commodity and has a value determined "like any other commodity," the value of variable capital does need to be transformed into the concrete form of price of production (a task which evidently exceeds the scope of this paper). As a consequence, we think that the alleged solution of the New Interpretation is no solution at all.

In this sense, although otherwise writing from a similar perspective to the one just sketched out, Mavroudeas' aforementioned contribution offers more elements both to explain the relationship between the value of means of subsistence and the value of labor-power, and to overcome the shortcomings of the New Solution approach. Regarding the latter, this author rightly claims that commodity values must be explained by their *content* (*i.e.*, by socially necessary labor-time required for their production) and not by their *form* (*i.e.*, by the ratio in which they exchange against money in circulation). And although he admits that labor-power is a "peculiar" commodity ("since it only exists as a capacity of the living individual . . . which is commodified in capitalism"), he argues that it does not follow from this that it is "a natural good that enters the market without any value, acquiring there a price" (Mavroudeas, 2001, 56). Mavroudeas thereby proceeds to analyze the production process of labor-power and makes two additional points. First, he agrees with New Solution scholars like Mohun that no new value is added in the "domestic" sphere of reproduction of labor-power on the very same grounds: the reproduction of labor-power entails "human effort but this is not expended through a capitalist production process," the upshot of which is that "there is no creation of new value or surplus-value and the sale of the commodity labor-power does not operate according to the rules of typical capitalist commodity exchange (obtaining an average rate of profit etc.)" (Mavroudeas, 2001, 56). Second, however, he also argues that the means of consumption required for the reproduction of labor-power are capitalistically produced by wage-labor and bought in the market, which means that they have a value determined by socially necessary labor-time. Crucially, and here Mavroudeas goes *beyond* what Marx *explicitly* states in *Capital*, he further submits that the value of the means of "subsistence" is *transferred* to labor-power through the workers' consumptive activity and therefore "this value has to be reflected in the price that is paid for buying labor-power (wage)" (Mavroudeas, 2001, 56).

There are three problems with this defense of Marx's argument on the value of labor-power. In the first place, it has no textual basis in Marx's exposition in *Capital*; not because he explicitly states otherwise, but because he does not discuss the question at all. Presumably, Marx took for granted that in light of the determinations already unfolded by chapter 6, it would be self-evident for readers why "human effort" expended in the domestic sphere could not be value-positing. As he unambiguously puts it in the section on commodity fetishism in chapter 1, "objects of utility become commodities only because they are products of the labor of private individuals who work independently of each other" (Marx, 1976a, 165). This leads us to the second problem.

For while Mavroudeas is right to point out that no new value is posited in the domestic sphere of individual or personal consumption, the grounds that he offers for that claim (which he shares with the New Solution) are essentially wrong. The expenditure of human labor-power within the domestic sphere does not create value not because it is not "expended through a capitalist production process with a view to obtaining the average rate of profit." The reason lies in the fact that the organization of the allocation of that portion of social labor in its particular concrete forms which takes place within the "household" is not mediated through *indirect* social relations between *private and independent* individuals (which, as argued elsewhere [Kicillof and Starosta, 2007a; 2007b; Starosta, 2016], is the ground of value-positing activity). The allocation of social labor within the domestic sphere is organized through *direct, personal relations* (the family). In other words, that portion of social labor does not possess "the peculiar social character of the labor which produces [commodities]" (Marx, 1976a, 165).[3]

Finally, although we shall see that Mavroudeas' point about the "transfer" of value from the means of consumption to the wage-worker's labor-power is broadly on the right track, he does not offer a convincing explanation of why and how this material and social process occurs.[4] Note, however, that neither does Marx's own presentation in Chapter 6 of *Capital* spell out, in any systematic fashion, the way in which the connection between the value of means of subsistence and the value of labor-power becomes concretely established over the course of the process of reproduction of the wage-worker. The link is just asserted. In order to make that connection explicit, we need to go beyond what Marx said on the question in *Capital*, albeit on the basis of determinations that are perfectly in line with his argument in the rest of the book.

---

[3] Of course, all products of capital are commodities, and only in the capitalist mode of production social wealth universally takes on the commodity-form. Yet, it does not follow that the value-form of social wealth is grounded in the fact that it is immediately ruled with a view to valorizing an individual capital. The simplest determination of the value-form is given at the level of abstraction of the commodity as a *presupposition* of capital. This is what grounds the *content* of the value-determination. By contrast, commodity production under the command of an individual capital with a view to obtaining the average rate of profit (*i.e.*, the commodity not as a methodological–systematic *premise* but as *result* of the movement of capital) determines the *concrete form* in which value is realized (*i.e.*, the price of production). For a methodological discussion of the commodity as presupposition and result of capital, see Marx, 1976b, 953ff.

[4] The reason given by Mavroudeas is that "contrarily to consumption goods consumed by capitalists (luxuries), workers' consumption is a productive activity and they transfer their value to the commodified aspect of human reproduction (labor-power)" (Mavroudeas, 2001, 56). At least on the basis of this statement alone, it is not clear to us in what sense the workers' consumption is a *productive* activity.

The Value of Labor-Power

A first relevant element for this discussion can be found in the *Economic Manuscripts of 1861–1863*. In that text, in the context of a critique of Bailey's "silly" (*sic*) objection to Ricardo's determination of the "value of labor," Marx makes the point, not mentioned in *Capital*, that the determination of the value of labor-power by the value of the *means of subsistence* is not peculiar to that particular commodity but applies to all "organic" commodities; for instance, it applies to the value of animals as well (Marx, 1988, 48). Moreover, he makes clear that the way in which the means of subsistence enter in the "price of labor capacity" is through the "metabolic process," *i.e.*, through the "exchange of matter" involved in the process of individual consumption of those means of subsistence by the bearer of human labor-power.

> The price of CLOTH does indeed consist also of the price of the cotton yarn consumed in it, just as the price of labor capacity consists of the means of subsistence that enter into it through the metabolic process. Incidentally, the reproduction of living, organic things does not depend on the labor directly applied to them, the labor worked up in them, but on the means of subsistence they consume — and this is the way of reproducing them. Bailey could also have seen this in the determination of animals' value; even in the case of machines, in so far as coal, oil and other *matières instrumentales* consumed by them enter into their cost. . . . Otherwise Bailey's joke only has the upshot that the labor applied to the reproduction of the organic body is applied to its means of subsistence, not directly to the body itself, since the appropriation of these means of subsistence through consumption is not work but rather enjoyment. (Marx, 1988, 48.)

In other words, the "transfer" of the value of means of subsistence to the commodity labor-power takes place through the material change of form of those use-values into the bodily (physical and intellectual) productive attributes of the wage-worker. Similarly to the transfer of the value of means of production to the final product, one could say that the value of means of subsistence, as Marx puts it, "undergoes a metempsychosis" (Marx, 1976a, 314). Through this "transmigration," value "deserts the consumed body to occupy the newly created one" (Marx, 1976a, 314). The analogy, however, stops here.

For unlike means of production, labor-power is *not*, in and of itself, a use-value (Iñigo Carrera, 1995, 5).[5] In other words, it is not in itself a *means* for human life, "a thing that through its qualities satisfies human needs of whatever kind" (Marx, 1976a, 125), although its existence is clearly a condition for the specifically human process of material metabolism. However, although human labor-power is not a use-value by its own material nature, it *becomes form-determined as such when subsumed by capital as the active condition for its valorization.* In effect, given the private form taken by social production, labor-power embodies the capacity to produce value and, more specifically, more value than it costs. (Surplus)value-positing for capital becomes its *form-determined* use-value.[6] Thus, it is the constitution of the value-form into the alienated subject of social life that turns labor-power into a use-value, by determining the exercise of that human capacity as the immediate source of its self-expansion.

As Marx shows in Chapter 23 of Volume I on "Simple Reproduction," the constitution of the total social capital into the subject of the movement of society reaches its plenitude when subsuming material *reproduction* in its unity, *i.e.*, when it subordinates not only social production and circulation, but also the process of individual consumption (Marx, 1976a, 711ff). As a consequence, the unity of the human metabolic process becomes inverted into a moment of the reproduction of capital. The implication of this is that in capitalist society the process of individual consumption does not bring each cycle of the process of metabolism to a close. In other words, in the capitalist mode of production individual consumption in the domestic sphere is not synonymous with *final* consumption, as economics, both "classical" and "vulgar," would have it (Ricardo, 1821, 339; Jevons, 1871, 47; Keynes, 1936, 104). The latter moment is reached in the sphere where labor-power is consumed for the production of more value than its reproduction costs, *i.e.*, in the phase of *productive* consumption or the labor process. This is crucial for the link between the privately undertaken socially necessary abstract labor-time materialized in the means of subsistence and the value of labor-power. Let us examine the matter more closely.[7]

---

[5] Note that transformation of the use-value of means of production into a new use-value is for Marx a necessary condition for the "transmigration" of their value to take place: "The reason why means of production do not lose their value at the same time as they lose their use-value is that they lose in the labor process the original form of their use-value only to assume in the product the form of a new use-value. But however important it may be to value to exist in, it is still a matter of complete indifference what particular object serves this purpose" (Marx, 1976a, 310).

[6] This, we take it, is the meaning of the following passage from the original text of *A Contribution to the Critique of Political Economy*: "For money as capital, labor capacity is the immediate use value for which it has to exchange itself. In the simple circulation, the content of the use value was indifferent, dropped out of the economic determination of form. Here it is its *essential economic moment.* For the exchange value is determined as firmly established in exchange above all because it is exchanged with *a use value confronting it in its own form determination*" (Marx, 1987b, 504).

The workers buy those means of consumption in order to reproduce their life as social subjects. In doing so, the value objectified in them is realized since the private labor that had been expended on them is confirmed as socially necessary. Those use-values are then taken to the domestic sphere of individual consumption, where they are either consumed straightaway if their materiality was immediately apt for the satisfaction of a human need, or subject to a further labor process. However, we have seen that in this latter case the objectification of social labor does not result in its representation in the social form of value.

Now, when those use-values are consumed, their materiality does not simply vanish but only changes form into reconstituted labor-power which, as argued above, is not in itself a use-value. Hence, if the immediate aim of the social reproduction process were the reproduction of human life (as would happen with a simple circulation of commodities), this transformation of the materiality of means of consumption into productive attributes of the human subject would bring this particular cycle of social reproduction to a close. Thus, even if those use-values had the commodity-form, their value would disappear definitively with that consumptive appropriation of their materiality.

However, we have further argued that from the point of view of the alienated organization of human life as an attribute of capital, that process does not close the cycle of social reproduction, but is only a passing moment in the process of value's self-valorization. Thus, the commodities consumed by the wage-worker must be turned into the production of his/her particular labor-power, that is, into the determinate productive attributes that the material conditions for the valorization of capital determine as a new use-value. Hence, from the general social point of view, the new form which those means of consumption acquire by being transformed in the renewed labor-power of the wage-worker still needs to prove socially necessary, which in this context does not mean that it is capable of satisfying a human want, but that it is able to valorize capital. In other words, the confirmation that the portion of social labor originally allocated privately in the particular concrete form of those means of consumption was socially useful entails a further mediation, namely: the success of the wage laborer at selling his/her labor-power as a commodity, *i.e.*, as a use-value that has been produced in a private and independent manner from the point of view of the form-determined *content* of the *unity* of the social metabolic process. *This is why the value borne by those means of subsistence does not disappear with their consumption in the household but reappears as the value of labor-power.* If the latter is effectively sold, then the social labor expended in the production of the means of consumption which the worker had consumed to reproduce labor-power is eventually confirmed as socially useful.

---

[7] In what follows we draw on Iñigo Carrera, 1995, 6–7.

Still, this does not yet bring the cycle of that commodity to an end. The realization of its use-value is still pending, a process that can only occur through its consumption. Therefore, only when the latter is effectively consumed (*i.e.*, exploited) by capital in the immediate production process as a specific use-value which is capable of producing surplus-value, that particular cycle of social reproduction is brought to a close. It is only at that stage that the use-value of labor-power (and so the changed form of the original means of consumption) suffers final appropriation and, with that, its value is eventually extinguished. On the other hand, that very consumption of labor-power by capital privately produces new commodities and hence, new value and surplus-value.

In sum, this discussion shows that there *is* a necessary *material* link between socially necessary labor-time expended in the production of means of subsistence and the value of labor-power. Although the mediations that connect the value of means of subsistence with the value of labor-power are not fleshed out by Marx, it is possible to establish that nexus in a way which is absolutely consistent with the general determinations of the value-form that he did present in *Capital*. In effect, we have shown that, with the proviso about the form-determined nature of its use-value, all the determinations of the commodity-form are present in the production of labor-power. Paraphrasing Marx, a "definite quantity" of privately undertaken socially necessary abstract labor "is objectified in it." That objectification of labor-time must therefore take on the value-form in order to manifest its general social character. The objections of critics to the commodity-nature of labor-power are therefore unfounded.

In light of this conclusion, in the next couple of sections we turn to the discussion of two classic Marxist controversies that touched upon the production process of labor-power: the debates on "domestic labor" and on "skilled labor." As we shall see, our approach to the reproduction of labor-power as commodity determined by the self-valorization of capital will prove to be very valuable in shedding light on many of the contentious issues involved in those debates.

The Domestic Labor Debate

This debate was motivated by the perceived need to investigate more thoroughly the labor process performed within the wage-worker's household (Benston, 1969; Morton, 1971). In the view of most of the participants, this task had not been undertaken satisfactorily within Marxism (Vogel, 2000, 156). Following on from Dalla Costa and James' contribution (1972), the attention of many scholars subsequently turned to Marx's argument about the quantitative determination of the value of labor-power. More specifically, several works made a case for the reconsideration of domestic labor as value-producing. Two different but converging arguments were put forward. In the first place, some authors argued that domestic labor is part of socially necessary labor for the production of labor-power and must therefore enter into the quantitative determination of its value and be reflected in the wage (Secombe, 1974). A second approach postulated that domestic labor is not immediately represented as the value of labor power, but indirectly as capital's surplus value or profit. In its more sophisticated version, this perspective maintained that the surplus labor of the domestic worker is appropriated by capitalists through the exchange of labor-power against a wage that does not pay for all the labor-time "objectified" in it (Harrison, 1973; Gardiner, 1976).

Various objections were raised against this broad "heterodox" perspective, the main one being that domestic labor is not subordinated to the law of value insofar as it is neither performed under capitalist relations of production (Himmelweit and Mohun, 1977), nor organized with a view to exchange (Smith, 1978). Hence, these critiques went on, concrete labor performed in the household cannot be reduced to socially necessary labor and therefore cannot be value-producing. In sum, these critics rejected the validity of the social identification of domestic and wage labor, which is precisely what the original contributions had assumed. Now, although we concur with these critics that it is incorrect to consider domestic labor as (surplus)value-producing, those original contributions had nonetheless the merit of providing an in-depth and detailed examination of the processes involved in the (re)production of labor-power. In some cases, those contributions even hinted at the aforementioned problem of the "transference" of the value of means of subsistence into the commodity labor-power. As a matter of fact, the pioneering work by Inman from the 1940s had already submitted that "the value of the commodities consumed by the worker's family . . . reappear[s] again on the market, but in a new form, as the commodity labor-power" (Inman, 1942, 45, cited in Thomas, 1987, 331). As mentioned above, this insight is crucial for the determination of the value of labor-power by the socially necessary labor objectified in the means of subsistence and, *a fortiori*, for the commodity-nature of labor-power.

Be that as it may, the point is that as a result of this debate, many Marxist scholars were led to question Marx's overall argument regarding the determination of the value of labor-power. Thus, Philip Harvey (1983, 308–310) suggested that if the value of means of subsistence reappears in the value of labor-power, this necessarily means that the workers' individual consumption is in reality a labor process, which utilizes those means of subsistence as means of production of labor-power. But if this is the case, Harvey continues, this "labor of productive consumption" must be considered as socially necessary for the production of labor-power. And the same goes for domestic labor that further transforms means of subsistence originally purchased as commodities with the wage. On these grounds, and in the face of the fact that Marx did not include these expenditures of human bodily powers in the determination of the value of labor-power, Harvey concluded that Marx's approach does not actually constitute a "labor theory" of the value of labor-power but a "cost of production theory" (P. Harvey, 1983, 307, 312). In other words, the value of this "peculiar commodity" *is not, pace* Marx, determined "as in the case of every other commodity" by the "labor-time necessary for the production . . . of this specific article" (Marx, 1976a, 274).[8]

From our perspective, these analyses reach these problematic conclusions because they overlook the essential determination at stake in the transference of value between different use-values, namely: the need to re-validate the social character of privately performed labor. This is a process that is generally mediated by productive labor but that, in the context of the overall movement of reproduction of the total social capital, takes place as well through individual consumption. As argued at great length above, the abstract character of privately performed labor objectified as the value-form of means of subsistence does not attain definitive recognition as socially necessary at the moment of their purchase by the working class family. This only occurs when the capitalist buys their labor-power with the aim of valorizing his/her capital and subsequently consumes them productively in the direct production process. Only at that point is the formal use-value of labor-power finally extinguished and its value therefore disappears. Hence, the reappearance of the value of means of subsistence as the value of labor-power simply expresses the need to reassert, under the new guise assumed by those use-values, the social character of the privately performed labor originally objectified in them. In other words, this "transfer of value" is quite simply derived from the general determination underlying the value-form of the product of labor: it is the reified form through which the immanent social determinations of human productive activity are represented when they are indirectly organized through the general production and exchange of commodities.

Why, then, is the labor performed in-between the wage-worker's purchase of means of subsistence and the sale of labor-power *not* represented as its value? The answer to this question cannot just come down to saying, as in most critiques of the "heterodox" camp in the debate, that "domestic labor" is not subordinated to the "law of value." As a matter of fact, this is precisely what needs to be explained. Thus, the *reason* why this labor is not value-producing is that *it is not private labor vis-à-vis the immediate consumer of its product.* And note that this applies *both* to reproductive labor undertaken by the worker him/herself (which is not even *social* labor) and to work performed by other family members (which is social since it is done for another individual, *i.e.*, the wage-worker, but *directly* so, *i.e.*, its social character is organized through *personal social relations*). This point can be further clarified through a comparison with the domestic labor undertaken by a hired cleaner or cook. In the latter case, it does create value, since we do have an instance of privately performed social labor *vis-à-vis* the immediate consumer of its product, which thereby does take the commodity-form (as much as the labor that, for instance, produces the meals that the worker eats at a restaurant; the fact that the former occurs in the household is immaterial). As a consequence, the "domestic labor" performed by a hired cleaner or cook does enter into the determination of the value of labor-power.[9] Thus, the feminist *normative* claim that reproductive labor be considered as value-producing is revealed as underpinned by an essentially ahistorical or Ricardian conception of value, insofar as it considers that all productive expenditure of labor-power is value-producing regardless of its "peculiar social character" (Marx, 1976a, 165).

---

[8] Some years later, Thomas (1987, 127) tried to avoid these conclusions by arguing that the only labor that transfers value is "commodity-producing, value-creating labor." Hence, Marx's argument needed to be amended in order to incorporate the fact that domestic labor produces value. In this way, she reinstated the feminist critique that considered Marx's approach as incomplete (if not directly flawed).

In sum, it is perfectly possible to explain the parts respectively played by the domestic productive and consumptive processes in the formation of the value of labor-power, on the basis of Marx's "value-form theory." All privately undertaken socially-necessary labor for the production of this "peculiar commodity" is represented as its value, while all directly social necessary labor is not. Therefore, the critique of Marx's analysis of the value of labor-power stemming from the "domestic labor debate" is ill-founded. The lack of conceptualization of this labor in the determination of value is not a "blind spot" of the Marxian critique of political economy (Werlhof, 1988). It is perfectly consistent with the "purely social objectivity" of the value-form that Marx discovered.

---

[9] In this sense, it must be acknowledged that Marx's presentation in *Capital* is not entirely satisfactory in this regard. Thus, he claims that labor-power has value like all other commodities because "it represents no more than a definite quantity of the average social labor objectified in it" (Marx, 1976a, 274). For the sake of rigor and clarity, he should have actually referred to "privately undertaken average social labor objectified in it." In other words, only commodities (and not simply use-values) consumed by workers enter into the determination of the value of labor-power. In Marx's defense, it was probably a shorthand expression which, even if not entirely correct, was seen by him as harmless in light of the rigorous and lengthy exposition of the determinations of the commodity-form contained in the first section of *Capital* (cf. his remark on overlooking the difference between value and exchange-value for the sake of brevity once the dialectical exposition has established their "unity and difference"). Besides, in the *Economic Manuscripts of 1861–1863* he made the point explicitly: in its general determination, "the means of subsistence needed for the maintenance or reproduction of labor capacity can all be reduced to commodities" (Marx, 1988, 43).

The Skilled Labor Debate

The question about the kind of labor expended to produce labor-power and, more specifically, about its preservation or destruction in subsequent phases of capital's overall circulation process has been at the center of another important controversy within Marxism, namely: the skilled labor debate. In this section, we review the main positions in the debate and offer some reflections on the way in which our reconsideration of the determinations of the commodity-nature of labor-power can shed light on many of the apparent difficulties posed by the "multiplied" value-producing powers of skilled labor.

The debate on skilled labor was initiated by Böhm-Bawerk's well-known criticism of Marx's value-theory (Böhm-Bawerk, 1890; 1949). According to this author, the Marxian explanation of the equalization of qualitatively different labors fails because the argument unfolds "in a complete circle": it starts out in search for an explanation of the exchange relation but, insofar as it is argued that "the standard of reduction [of skilled to simple labor] is determined solely *by the actual exchange relations themselves*," it ends up accounting for the exchange relation on the basis of that very same exchange relation! (Böhm-Bawerk, 1949, 83). The first line of reply provided by Marxists was that the greater value of the product of skilled labor is not explained by the exchange relation, but by the greater value of more complex labor-power. According to this conception, the higher the value of labor-power, the greater will be the magnitude of value that results from its objectification (Bernstein, 1900).

However, other Marxists very soon took this explanation to task for relapsing into a theory of value founded on "costs of production."

As Hilferding noted, Bernstein's explanation wanted "to deduce the value of the product from the 'value of labor'" (Hilferding, 1949, 141). As an alternative, Hilferding and other authors proposed a procedure for the reduction of skilled to simple labor based on the addition of the quantities of simple labor that materialized in the production of skilled labor-power and which, indirectly, become "condensed" in the actual expenditure of the latter. More specifically, according to these authors these "formative labors" included both the work of the "technical educator" (Hilferding, 1949, 144) and that of the skilled laborer (in his/her capacity as student) (Bauer, 1906). Those past formative labors, Hilferding states, "are stored up in the person of the qualified laborer, and not until he begins to work are these formative labors made fluid on behalf of society" (Hilferding, 1949, 144).

Until the mid-1970s, the Hilferding–Bauer approach was widely accepted by Marxists as the definitive response to Böhm-Bawerk (*e.g.*, Sweezy, 1942; Meek, 1956; Rowthorn, 1974). However, soon after that some Marxists started to raise some reservations against the alleged solution to the "reduction problem." In the first place, it was argued that the Hilferding–Bauer reduction procedure implied different rates of surplus value for skilled and simple labor which, it was claimed, contradicted the Marxist theory of exploitation (Morishima, 1973). Second, other scholars argued that in conceiving of the worker's skills as the material condensation of past labor that would subsequently be represented in the higher value of the product, the productive attributes of workers were treated as constant capital (Tortajada, 1977). In relation to the first of these objections, let us note that the existence of different rates of surplus value leaves the general qualitative determination underlying the exploitation of wage-workers untouched. In effect, regardless of the relative complexity of his/her labor-power, each worker performs (on average) as much labor for capital as the normal long-term reproduction of his/her labor-power allows. And he/she receives in exchange an equivalent of the socially necessary labor time for the reproduction of those productive attributes that capital demands from him/her. The fact that this might result in different rates of surplus value for labor-powers of different qualifications only affects the degree in which capital will appropriate unpaid surplus labor. But it does not compromise the validity of Marx's explanation of the source of surplus value in the exploitation of the wage-worker. Furthermore, these varied rates of surplus value are immaterial for the individual capital, insofar as it could be argued that this is but another differential condition of valorization that becomes averaged out through the formation of the general rate of profit (similarly to differences in the organic composition or turnover rates).

By contrast, the second objection does pinpoint a real flaw in the traditional "reduction method," insofar as the latter involves a departure from the general determinations of value and surplus value. More specifically, it parts company with Marx's argument that it is only the expenditure of the living labor of the worker that posits new value in the product, while the value of constant capital (*i.e.*, "past labor") is only "transferred" in the same magnitude. In postulating that the value of the product of skilled labor includes the "past labor" materialized in the more skilled labor-power, the classic solution ends up effectively conflating constant and variable capital. On this score, we concur with those who rejected the Hilferding–Bauer train of thought.

In the face of these shortcomings of the traditional reduction procedure, new alternative solutions appeared that changed considerably the very terms of the problem without, however, achieving any consensus. Thus, some scholars proposed that the reduction of skilled to simple labor should be regarded as a real and observable process of de-skilling of labor-power resulting from capital's transformation of the labor process (D. Harvey, 1982; Itoh, 1987; Carchedi, 1991), while others opted for considering skilled labor quite simply as more productive (P. Harvey, 1985; Bidet, 2007; Saad-Filho, 2002). In our view, rather than solving the "skilled labor" reduction problem, these alternative just sidestep it. By contrast, we think that our approach to the determination of the value of labor-power sketched out above offers a valuable and novel way to critically examine the classic Hilferding–Bauer reduction procedure and to develop a more rigorous explanation of the "multiplied" value-creating powers of skilled labor.

In the first place, having demonstrated that labor-power is a fully-fledged commodity we know with certainty that its value is exclusively determined by the privately performed socially necessary abstract labor required for its production. Moreover, insofar as capital's productive consumption of labor-power closes the form-determined cycle of social reproduction, this value disappears through the expenditure of the worker's living labor in the direct production process.

Consequently, regardless of the degree of complexity embodied in the worker's labor-power, no single "atom" of its value can be preserved and transferred to the product of his/her labor. In this sense, the labor of the "technical educator" or the labor objectified in a textbook are hardly different from those labors objectified in the most prosaic of commodities that the worker consumes during his/her lunchtime. Assuming that they have the commodity-form, they are all part of the privately undertaken socially necessary labor required for the production of the commodity labor-power and, in that condition, they are absolutely independent of the labor that the worker will perform when setting his/her labor-power into motion in the capitalist labor process.

Now, Hilferding–Bauer and their followers obviously think that their reduction procedure avoids Bernstein's error of grounding the value of the product of skilled labor in the value of skilled labor-power. However, it seems to us that by including in the value of the product of skilled labor the socially necessary labors required for the production of skilled labor-power, they end up relapsing into a similar elementary mistake, namely: conflation of the *value* of labor-power (the "past labor" objectified in it) and its *use-value* (the value-positing capacity of living labor in action). As stated above, there can be no trace of the past labor required for the production of skilled labor-power in the "multiplied" value-positing powers of skilled *living* labor in action. The central question still stands unanswered: how is the higher value of the product of skilled labor explained?

Again, here we think that the answer must be: "as in the case of any other commodity," *i.e.*, by the privately performed socially necessary abstract labor required for its production. The key, of course, resides in being absolutely clear and precise about which private labors are socially necessary *just* for the production of the *product of skilled labor*. And these come down to the living labor of the skilled worker, the "dead" labor objectified in the means of production consumed by living labor in the capitalist production process and, crucially, the labor expended *by the skilled laborer himself/herself* (*i.e.*, not by the "technical educator") with a view to acquiring the skills that are *socially necessary for the production of the said commodity*. As we have seen, the latter is a kind of labor which, insofar as it is not private from the point of view of the production of (skilled) labor-power, does not enter into the determination of its value. However, it definitely is private and socially necessary from the perspective of the production of the use-value that the skilled laborer will produce under the command of the capitalist. For that reason, it enters into the value of the product of skilled labor.

Clearly, this admittedly succinct answer does not address all the complexities and subtleties involved in the debate over the reduction of skilled to simple labor, a task which exceeds the scope of this section.[10] However, this discussion should suffice to shed light on the gist of the solution to this long-standing difficulty in Marxist value theory: the rigorous identification of the opening and closing phases of each capital-determined cycle of social production and consumption and, as a consequence, of the exact amount of privately performed socially necessary abstract labor that is required for the production of each particular commodity.

Conclusion

This article has critically examined the rejection of the commodity-nature of labor-power based on the broad argument that it is not produced under the direct command of capital. Although its lineage can be traced back to the early 20th century, this long-standing argument gained new life recently in association with the so-called New Solution approach to the transformation problem. This perspective has encountered some valid critical reactions which, however, have not offered a solid and conclusive alternative. In light of this, we took up the challenge and attempted to develop an explanation of the fully-fledged commodity-character of labor-power on the basis of Marx's own analysis of the value-form but beyond what he explicitly stated in *Capital*.

In a nutshell, our contribution revolved around the clear identification and differentiation of the specific social character of all the labor involved in the production of labor-power, *from the point of view of the reproduction of the total social capital*. It is the latter which, as the general social relation presiding over the movement of present-day society, gives unity and content to the human life-process. The crucial upshot of this for the purpose of grasping the commodity-nature of labor-power was two-fold. First, only privately undertaken social labor can form the value of labor-power. Second, when subsumed under the overall movement of the total social capital's reproduction, the privately performed labor required for labor-power's production attains final validation of its social usefulness only when it is exploited by capital in the direct process of production. This was the key link to explain the reappearance of the value of means of subsistence as the value of labor-power. On these grounds, we were able to reach the same conclusion that Marx reaches in chapter 6 of Volume I of *Capital*, namely, that the value of labor-power is determined, just "as in the case of every other commodity," by the (privately performed) socially necessary labor for its production. However, unlike Marx's unmediated assertion, we unfolded all the mediations that are necessary to validate that claim.

---

[10] One of the issues not addressed in this paper is the consistency of the different solutions with the scarce number of quotes by Marx that treat the subject of skilled labor. For instance, in one highly controversial passage Marx states that the respective rates of surplus value of skilled and simple labor are equal (Marx, 1981, 241). From our perspective, Marx was probably assuming that the use-values needed for the daily reproduction of each type of labor-power are identical, so that if the skilled laborer expends a working day at home to acquire the skills, the subsequent expenditure of skilled labor-power will objectify twice the amount of value. But since his/her labor-power will have cost twice, the rate of surplus value will remain the same.

As we have seen, this approach to the value of labor-power not only offers a way of grounding one of the fundamental categories of the critique of political economy. In addition, it provides useful tools to overcome the impasse reached within two classic Marxist controversies that have an intimate connection with the social processes underlying the production of labor-power and its form-determinations as a commodity, both as a *value* and as a *use-value*: the debate on domestic labor and the debate on skilled labor. Regarding the former, we have seen that our approach can shed light on the only reason why domestic labor is not value-producing. Briefly put, it is a part of social labor that is organized through direct personal relations, *i.e.*, that is not privately performed *vis-à-vis* the consumer of its product. As for skilled labor, we showed that the only way to be consistent with its definition while avoiding the confusion between the value and the use-value of skilled labor-power, is to grasp that only the "formative labor" undertaken by the wage-laborer himself/herself is private *vis-à-vis* the final consumer of the commodity that he/she will eventually produce under the command of capital. For this reason, only this privately performed socially necessary labor must be added to the productive living labor of the skilled worker in order to determine the value of its product. In sum, we have seen that in both the case of domestic labor and that of skilled labor, the key to resolving the issues that gave rise to the respective debates, consists in the clear understanding of the part that they play in the overall cycle of valorization of capital.

CHAPTER 1

Introduction: The New International Division of Labour and the Critique of Political Economy Today

Greig Charnock and Guido Starosta

> Thus, from the bare enumeration of some of the more glaringly obvious features of the present-day world economy, it can be seen that the old or 'classical' international division of labour, by which the underdeveloped countries were on the whole incorporated into the capitalist world economy as mere raw materials suppliers, no longer exists. The underdeveloped countries are increasingly chosen as sites for manufacturing industries producing goods that are competitive in the world market.
>
> … This tendency will be designated the '*new international division of labor*' (to be considered as an on-going, not a completed, process) (Fröbel et al. 1978: 845, 849).

In a recent anthology of his essays on *Global Capitalism* (2015) Hugo Radice recounts how in the 1960s and early 1970s progressive, broadly Marxist, scholarship fell short of providing a satisfactory means of understanding what was by then a rapidly changing world. The debates

back then, he summarises, ‘had little to say directly about the transformations of production and work within firms, or about the political relations between organised economic interests and the state, while international economic relations between states were understood firmly in nineteenth century terms of autonomous and mutually antagonistic powers, great or small’ (Radice 2015: 9). Yet profound and lightning-paced transformations in worldwide production and trade were indeed palpable to any observer back then, and by the mid-1970s Marxist scholars in the UK and beyond were beginning to engage in highly productive—and still influential—debates on the labour process, state theory, and alternative political strategies in the context of deep world recession and heightened social and political tensions across much of the West. Radice recalls, in particular, his participation in a 1974 workshop in Starnberg, Germany, ‘at which Otto Kreye and his colleagues presented the first results of their project on the new international division of labour’. This work, he confirms, was to become ‘very influential for progressive scholarship on global capitalism’ (Radice 2015: 9).

The new international division of labour (NIDL) thesis developed by Folker Fröbel, Jurgen Heinrichs, and Otto Kreye very much stands out as one of the most influential and widely debated contributions at the forefront of discussions on late-industrialisation and global production long into the 1980s and 1990s. Based on their empirical studies in the 1970s, Fröbel, Heinrichs, and Kreye’s work seemed to capture extremely well the transformations in the world market taking place by the beginning of that decade, and very rapidly caught the attention of most analysts of international political economy (IPE) and the changing geographies of global capitalism. Although the argument in their book *The New International Division of Labour* (published in English in 1980) rested on very distinctive theoretical foundations and arguments, reviewed below, the expression ‘new international division of labour’ was to somehow acquire a life of its own and soon became very much a part of the working vocabulary of most scholars empirically concerned with global processes of industrial restructuring—a kind of conceptual shorthand to encapsulate what were regarded as the main developments in the world economy at that time. The ‘NIDL’ thus became a catchphrase, widely accepted and loosely used (sometimes by default) to *describe* the novel configuration of the capitalist world market, but without always making a self-conscious effort to acknowledge or flesh out the particular conceptual approach being deployed to *explain* this empirical phenomenon and its subsequent developments.

In a nutshell, the popularised version of the NIDL thesis consisted of the following stylised account of the process of global restructuring. Faced with declining profitability in advanced capitalist countries (mainly due to rising wages), transnational corporations (TNCs) started to relocate labour-intensive manufacturing to the then, so-called, Third World, thus acting as a major factor in the industrial decline that seemed to prevail in the former countries in the late 1970s and early 1980s. 'Third World' countries, for their part, provided TNCs with a huge potential reserve of low-paid and disciplined workers. Combined with technological advances in the means of communication and transport, the increasing fragmentation of production processes and the consequent simplification of semi-skilled and unskilled tasks created a tendency for the establishment of export-oriented 'world market factories' in the 'Third World'. Accordingly, the story went on, the classical international division of labour (CIDL)—revolving around the polarisation of the world economy into an industrialised 'core' and a dependent 'periphery' confined to the role of supplier of raw materials and staple foods—had been superseded by the NIDL, with an industrialised but still dependent Third World, and a 'First World' oriented to a service-based economy, which could not absorb the resulting unemployed population.

The NIDL thesis remained highly influential into the 1990s but—if the scant number of studies published in the last decade dealing directly with the NIDL is any indication—the thesis has since become passé. Undoubtedly, this can be explained in part by changing fads and the development of new lines of inquiry and debate among academics. Yet it is also the case that some scholars had started to put forward strong reservations against the NIDL approach by the 1990s—prompted principally by some empirical developments which seemed to contradict the major claims of the NIDL thesis. The 'impressive' developmental record of the first generation of Asian Tigers (especially South Korea), in particular, seemed to undermine a theory that put export-oriented industrialisation based on extremely low wages in labour-intensive industries at the heart of its argument. More broadly, as many critics have rightly highlighted, the initial formulations of the NIDL thesis contained untenable sweeping generalisations, which could not account for national differences in the developmental path of many countries. The industrial upgrading of the first generation of Asian Tigers, for example, would eventually include relatively complex, capital-intensive sectors rather than simply unskilled-labour-intensive ones, as the stylised version of the NIDL that became common currency appeared to suggest.

While accepting the veracity of some of the criticisms levelled at the original NIDL thesis and the version of it that became common currency by the 1990s, we believe that it now deserves to be revisited. We propose that a *properly reconsidered and revised* NIDL thesis can still shed light on the specificities of capitalist development in various parts of the world today, as well as the nature of uneven development across the capitalist world market. Taken together, the contributions to this book represent the basis for such a reconsideration of the NIDL thesis which rests upon the Marxian distinction between the global economic *content* that *determines* the constitution and dynamics of the international division of labour, and the evolving national political *forms* that *mediate* its development. More specifically, the book argues that national developmental processes across the world have been but *an expression of the underlying essential unity of the production of relative surplus-value on a world scale.* The fact that the approach taken in this book is rooted in the critique of political economy originally developed by Karl Marx over 150 years ago does not detract from its contemporary significance. Moreover, a revised NIDL thesis as put forward in this volume represents an original contribution to key debates in international and critical political economy, insofar as, firstly, its theoretical foundations lie in research that moves to some extent beyond Marx; and, secondly, it departs in significant ways from not only Fröbel and his colleagues, but also a variety of contemporary approaches that seek to understand the nature of—and the relation between—global transformation and uneven development.

FROM THE CRITIQUE OF POLITICAL ECONOMY TO A *NEW* NEW INTERNATIONAL DIVISION OF LABOUR THESIS

The book draws its inspiration from innovative theoretical scholarship that has emerged under the auspices of the Centre for Research as Practical Criticism (CICP), based in Buenos Aires, Argentina, and especially the work of the independent scholar Juan Iñigo Carrera. This work, which is only just recently beginning to appear in Anglophone literature—in part, because it has been developed outside of formal academic structures and networks[1]—represents a thorough re-examination of Marx's critique of political economy and its dialectical-methodical foundations. While drawing upon Marx's fundamental insight into the determination of capital as the immediate subject of the organisation of the process of social life, it also moves some way beyond it so as to cast fresh light on global transformation and uneven development in recent decades, as well as to offer ground-breaking research on the emancipatory subjectivity of the working class (a theme we do not broach directly in this book but see, for example, Starosta 2016). The following section outlines the basic contours of the approach pioneered by Iñigo Carrera.

Capital, the System of Machinery and the International Fragmentation of the Productive Subjectivity of the Global Working Class

As Starosta explains in Chap. 4, one of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (such as a firm), nor a social grouping sharing common characteristics and interests (for instance, business or the bourgeoisie). In its general determination as self-valorising value, capital is actually a materialised social relation between commodity owners differentiated into social classes, which, in its fully developed form as the total social capital, becomes inverted into the (alienated) subject of the unity of the process of social reproduction and its expansion (Marx 1976: 763). Thus, *capital* is essentially the movement of the self-expansion of the objectified general social relation between private and independent human beings which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976: 723–4; Marx 1992: 185). All moments of the human life-process thus become inverted into material bearers of the life-cycle of capital, or they become forms assumed by the flow of value in its circulatory process. Subsumed under the capital-form, the alienated content of social life becomes the production of surplus-value or the formally boundless quantitative progression of the general reified form of social mediation (Marx 1976: 251–7).

Although this content governs the movement of capital as a whole or as an alienated collective power, the *total (global) social capital* is nonetheless the product of the private and independent form taken by social labour. The general unity of the movement of the total social capital cannot be established immediately. It is thereby indirectly established through the exchange of commodities resulting from the apparently autonomous actions of individual capitals in competition with each other, as each of them pursues the maximisation of its profitability through the expanded reproduction of their formally independent cycles of valorisation. In their simplest form, those cycles can be represented through the well-known general formula of capital:

$$M-C\begin{matrix}\mathrm{LP}\\ \\ \mathrm{MP}\end{matrix}\quad \ldots..P\ldots\ldots\ldots C-M+\Delta M$$

Where M = money capital, C = commodity capital, P = productive capital, LP = labour power, MP = means of production. More specifically, the concrete form in which individual capitals assert their class unity as 'aliquot parts' of the total social capital is the process of formation of the general rate of profit (Marx 1981: 298–300, 312). This is the inner or essential determination of the general social relation between capitalist firms (or individual capitals).

The territorial or spatial dimension of the accumulation process—and the changing forms of the worldwide division of labour—therefore cannot be seen as being *determined* by the conscious locational 'strategies' of TNCs faced with given qualitative national and regional differences, in turn seen as established by allegedly autonomous state policies. Instead, it needs to be grasped as an expression of the underlying formal and material unity of the essentially global contradictory dynamics of the accumulation of the total social capital through the production of relative surplus-value, which are *economically mediated* by relations of competition among individual capitals like TNCs (again, as opposed to *determined*), on the one hand, and *politically mediated* by the policies of the nation state on the other. These contradictory and crisis-ridden dynamics, which, in their most developed form as large-scale industry, fundamentally *entail the permanent revolution in the modes of exertion of the labour power of individual workers and of their articulation as a directly collective productive body or organism* (Marx 1976: 617), lie at the heart of the changing historical forms of the international division of labour.

The production of relative surplus-value in the form of large-scale industry entails four divergent tendencies in the development of the productive attributes of the global working class (Iñigo Carrera 2013: Chap. 2). First, it expands the productive subjectivity of the part of the collective labourer responsible for the advance in the conscious control of the movement of natural forces (that is, science) and its technological applications in the directly social organisation of the immediate production process.[2] Although not explicitly addressed by Marx in *Capital*, the benefit of historical hindsight makes it very easy for us to recognise how the total social capital deals with its constant need for the development of the productive powers of science and for the conscious organisation of the increasingly social labour process, namely, by engendering a special partial organ of the collective labourer (see Starosta 2016: Chap. 8). Capital requires from these workers ever more *complex* forms of labour. As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker' (Marx 1976: 517). Needless to say, inasmuch as this expanded productive subjectivity is nothing more than a concrete form of the production of relative surplus-value, the exercise of newly developed intellectual productive powers is also inverted into a mode of existence of capital in its movement of self-valorisation. Moreover, sooner or later many of these intellectual dimensions of living labour will also experience automation (or knowledge codification) and therefore become relatively simplified. As we shall see later in this book, this latter aspect has been central to the more recent phases in the evolution of the NIDL (as shown in Chap. 6 through a discussion of the Irish software industry).

Second, it tends to degrade the subjectivity of those workers that acquire and exercise their increasingly simpler manual or experienced-based productive attributes in the direct process of production. Indeed, large-scale industry is based on the objectification of *tacit* knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes, as an attribute of the system of machinery (Huws 2006). In this sense, the impact of capitalist automation certainly tends to be one of 'deskilling' or degradation of direct production work through the objectification of formerly manual tasks as functions of machines. Yet the effect of increasing automation has not just been one of deskilling. It has been mixed, also entailing a certain creation of new skills required by capital even from direct production workers. The key point, however, is that these newer skills have been of a different *kind* from those that have been eroded. While the older skills tended to be based on the *particularistic* development of the productive subjectivity of wage-workers (both manual and intellectual) as a result of the practical experience of machining in the direct process of production, the newly created skills tend to revolve around the *universalistic* dimension of the productive quality of labour-power, whose development is achieved in the general process of education and socialisation that precedes its actual application in the production process. For instance, and crucially for the general argument developed in the book, the 'microelectronic revolution' that is at the basis of the NIDL has entailed not only the degradation of the particularistic dimension of direct production work but also the emergence and generalisation of, so-called, soft or generic skills (see Ramioul 2006), such as familiarity with computers and flexibility or individual initiative in problem-solving or decision-making (Balconi 2002).

In the third place, while the new technologies have not resulted in the total elimination of manual labour from automated processes of production (Alcorta 1999: 164), they have recreated the conditions for the extended reproduction of what Marx called the 'modern manufacturing division of labour', that is those non-mechanised tasks and labour processes acting as an 'external department' of large-scale industry proper as the dominant form (Marx 1976: 588ff). This tendency has been fundamental for initial stages of the NIDL, which are the ones that Fröbel and his colleagues accurately but one-sidedly captured in the 1970s.

Fourth and last, the production of relative surplus-value through the system of machinery leads to the multiplication of the surplus population relative to the needs of the accumulation process, which also constitutes a transformation of productive subjectivity produced by the automation of large-scale industry (see Marx 1976: 553–75). More specifically, this tendency represents the most extreme case of material mutilation of the productive attributes of the working class resulting from capital accumulation, that is, not simply their degradation but their outright non-reproduction. Yet, it is from this tendency that the global pool of cheap but disciplined labour power, which has been central for the original constitution and evolution of the NIDL, has eventually derived.

What all the contributions to this book share is a conviction that the foundation of the uneven spatial differentiation of global capitalism must be searched for in these changing forms of the exploitation of the global working class by the total social capital, through the transformation of the material forms of the capitalist production process. The latter is, in our view, the *general content* that is realised in the political form of state policies (domestic and foreign) and class conflict, albeit behind the backs of the antagonistic actions of the personifications involved (social classes and their diverse political organisations, capitalist firms, 'political elites' and/or 'state managers'). Taking their cue from Iñigo Carrera's original approach, all the authors in this book see the transformations associated with NIDL as being products of the total social capital's drive to enhance the production of relative surplus-value on a world scale through the development of labour productivity, which finds its most advanced expression in the mechanisation of large-scale industry. Succinctly put, Iñigo Carrera's fundamental argument is that the 'essential' general content that defines the NIDL, and which has been reproduced under its evolving historical configurations since the 1950s until the present time, consists in the *international fragmentation of the productive subjectivity of the working class* (Iñigo Carrera 2013). Thus, as a result of its own immanent tendencies, the simplest original form of the NIDL—which we think Fröbel and his colleagues were right to identify as signifying an on-going process—has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class (through their impact upon their general conditions of reproduction and condensed in the so-called 'historical component' of the value of labour-power). Each country therefore *tends* to concentrate a certain type of labour-power of distinctive 'material and moral' productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner (Grinberg 2011: 35–6). Production in specific industrial sectors has thereby expanded in some countries while contracting in others where new and more advanced sectors have developed, following a rhythm determined by the evolution of two main factors, that is, technological change and relative cost and productive attributes of national labour forces.

This different constellation *does not* involve the transcendence of the NIDL, as many of the critics of the original thesis have suggested (see Chap. 4), but instead represents a more complex form assumed by the same general content. This was the content that the original formulation of the NIDL thesis by Fröbel, Heinrichs, and Kreye failed to uncover, influenced as those authors were by dependency and world-systems theories, and the view that different countries and regions of the world achieve different levels of development on the structural basis of 'unequal exchange'. And it is this content that has generally eluded alternative international and critical political economy approaches that seek in their own way to explain the specificity of national development and the relations between distinct national 'capitalisms' under conditions of 'globalisation' or of 'combined and uneven development'.

The Significance of This Approach for a Distinctive Understanding of Global Transformation and Uneven Development

We think that, whatever its shortcomings, the early debate over the NIDL in the 1980s (in particular, the contribution by Fröbel, Heinrichs, and Kreye) was indeed on the right track as regards grasping the specific nature of the recent transformations of the process of capital accumulation on a world scale. Thus, it actually provides richer material and a more fruitful starting point for a critical investigation of the determinations underlying the, so-called, globalisation process than many other contemporary international and critical political economy analyses. In this sense, we feel that the question of the NIDL should be put back on the agenda for a robust theorisation of global transformation and uneven development. There is no doubt, as conceded above, that the original debates around the NIDL left many theoretical and empirical questions unresolved. In particular, no contribution managed properly to account for the process of national differentiation as an expression of the underlying essential unity of the accumulation of capital on a world scale. The debate, in short, never resolved the tension between national and global dimensions in the articulation of the international division of labour. The significance of this book, then, is that taken together the contributing authors provide a basis for an alternative critique and reformulation of the NIDL thesis that, first, recovers what constituted its main achievement and which has been forgotten by contemporary theorising; namely, the understanding of national differentiation as an expression of the essential unity of the capitalist world system. Second, and by drawing on a particular reading of the Marxian critique of political economy grounded in the work of Iñigo Carrera, we believe the book provides a more distinctive foundation for the conceptualisation of that unity than can be found in Fröbel et al.'s *marxisant* world-systems theory. Let us elaborate.

Drawing directly upon the work of 'monopoly capital', 'world-systems' and 'dependency' theorists, Fröbel and his colleagues conceptualised the 'unequal development' they believed to be central to world capitalism in descriptive terms of: 'The splitting up of the capitalist social formation into "centre" and "periphery", and also possibly "semi-periphery", both intra- and inter-nationally, that is, the development of an international division of labour with different forms of control over labour for different types of production in different regions of the capitalist world economy'

(Fröbel et al. 1980: 32). In our view, attempts by world-system theorists to explain unequal development proceeded from a problematic theoretical-conceptual distinction between core and periphery. They sought to derive underlying, structural relations between different countries and regions on the basis of empirical evidence which suggested that capital-intensive production was concentrated in the core, that labour-intensive production was concentrated in the periphery, and that the international exchange relations between the core and periphery ensure the continuous development of the former at the expense of the latter.[3] Alongside, or overlaying, these international economic relations, they posited unequal political relations between countries engaged in competitive measures to promote or protect their own industries to the detriment of other countries' industries. At the root of this dualistic conceptualisation of unequal economic and political international relations is an analytical distinction between economics and politics that Radice (2009: 36) rightly, in our view, problematises for its confinement of 'class struggle to the realm of "politics", not realising that the existence of a separate realm of politics is in itself a condition of existence of capitalism'. Furthermore, this conceptualisation assumes that the 'central structural feature of "the economy" is the division of labour *in society*'—whether in national or international form—'rather than in manufacture, to use Marx's careful distinction' (Radice 2009: 34). In other words, it is *capital*—understood as an essentially global process—and not the external and contingent political and exchange relations established between a multiplicity of national states themselves, that *determines* their development. And it is capital's thirst to enhance the production of relative surplus-value, on the basis of the development of large-scale manufacturing and the fragmentation of the international working class, which is at stake in the historical development of the international division of labour, not the reproduction of relations of unequal exchange between domestic and international classes that are somehow socially and politically constituted outside of the global process of accumulation (see Chap. 2).

In any case, the fate of the NIDL thesis was not decided by critical theoretical engagement over the dubious assumptions of world-systems and dependency theories. Indeed, the demise of the NIDL thesis during the 1990s went hand-in-hand with a discernible move away from the consideration of *any* question of the structural unity of the global accumulation of capital by IPE and cognate literatures, and instead turned towards a widespread focus on national state institutions as autonomous drivers of economic development. Not least under the influence of neo-classical economists (such as Krueger 1990; Ranis 1989; Stiglitz 1996; World Bank 1993) and statist international political economists (notably, Amsden 1989; Evans 1995; Rodrik 1994; Wade 1990; Weiss 1998) who dominated debates on the efficacy and resilience of market-led co-ordination versus *dirigiste*, or state-led, development in the context of 'economic globalisation' (see Grinberg 2013: 173–8). As this debate ran out of steam in the late 1990s, scholars working in development studies and economic geography then embarked upon richly detailed research into global commodity chains, as a means of examining the impact of globalisation upon industrialisation in the developing world. While the foundational texts in this new paradigm were actually intellectually rooted in the lineage of monopoly capital and world-systems theory, the bulk of the emergent literature then arguably became highly descriptive and/or tended to focus on conceptualising industrial or business organisation on a 'network' basis (that is, based on the pure contingency of immediate direct social relations) and to the complete eschewal of the question of the constitution of 'commodity chains' and, later, 'value chains' and the dynamics of the global system as a whole (Starosta 2010). Meanwhile, in the IPE literature of the 1990s the question of explaining capitalist diversity became dominated by 'new institutionalist' approaches—not least the 'varieties of capitalism' approach pioneered by Hall and Soskice (2001)—which further compounded the tendency to focus upon the apparently autonomous constitution of individual capitalist states' institutional forms, at the expense of the consideration of what makes them 'capitalist' in the first place and the 'constitutive elements they hold in common' (Coates 2014: 21).

To be fair, a new generation of critical IPE and international relations scholars in recent years has at least sought to rectify the lack of a substantive theorisation of global transformation and uneven development in dominant debates, couched in questions of 'capitalist diversity' (Bruff and Ebenau 2014) or of 'uneven and combined development' (see Allinson and Anievas 2009). For us, however, these contributions have yet to offer a convincing, substantive basis for a 'unified field theory' of uneven development and the ever-changing geographies of capitalism—a necessity famously identified by David Harvey (2005: 58–9; see also Rioux 2015: 508; Smith 1989). Insofar as they do represent a welcome return to older, sidelined debates and canonical Marxist and *marxisant* literature, and an even more welcome exposé of the ideological nature of mainstream approaches, these new contributions ultimately run the risk of reproducing in new guises the problems we argue were already inherent in the classic literature: principally, in terms of explaining the concrete forms of 'variegated national capitalisms' and uneven development through the strategic and conscious action of key agents and 'social forces' that are somehow constituted outside of the process of capital accumulation; or in terms of resorting to the theory of 'unequal exchange' to explain 'underdevelopment'; or in terms of failing to *explain* the social determination of 'uneven and combined development', other than by means of a prior reliance upon the primacy of this under-theorised, abstract and trans-historical category.[4]

We suggest that the approach taken in this book can indeed provide such a unified field theory. By deciphering the national forms taken by the general content of an historically specific mode of the reproduction of total (worldwide) society, on the basis of the fragmentation of the productive subjectivity of the international working class, and through the development of the automation of large-scale industry within the NIDL, this book advances a substantive explanation of the inner relation between global transformation and uneven development that may well provoke criticism and debate, but which at least does so on distinctive and hitherto largely unfamiliar grounds.

Outline of the Book

The argument in Part I of this book—containing chapters by Iñigo Carerra, Caligaris and Starosta—sustains that Fröbel, Heinrichs, and Kreye were right to proceed from a global perspective on capital accumulation, and also right in the centrality they attributed to the recent material transformations of the capitalist labour process as key to the explanation of the developmental potentialities of late-industrialisation. On the basis of this critical re-examination of the NIDL thesis, the book goes on to argue that a revised NIDL thesis can shed new light on the specificities of capital accumulation in various parts of the contemporary world. Two particularly significant general insights emerge from these early chapters. First, that both the classical and new international divisions of labour should be most fruitfully re-signified in terms of the role played by *ground-rent* in specific national spaces of accumulation (a category explained in Part I). And second, that there remain essential continuities inherent to the classical international division of labour which necessitate that the current constellation of the world economy be understood as being constituted by the co-existence of both old and new international divisions of labour.

Such insights carry with them important and hitherto unacknowledged implications for the study of international political economy, and conclusions that contrast sharply with dominant critical and orthodox theories of global capitalism and uneven development.

The remainder of the book incorporates case study material on four countries in Latin America, two European countries, and one Southeast Asian country. The choice of national case studies in Part II is by no means arbitrary.[5] Each of the countries the respective authors examine is, in their own way, paradigmatic and emblematic of the essential dynamics of the NIDL that we are seeking to draw out theoretically and concretely in this book. Argentina and Brazil, for example, are the most visible examples of countries in which the structural characteristics of the CIDL persist and complement those of the NIDL to this day (certainly since the recent commodity export boom, and the revival of import substitution industrialisation under the Kirchners in Argentina). Ecuador and Venezuela represent the starkest examples of what Thomas Purcell in his chapter terms 'landlord states' within the contemporary international division of labour. And, notwithstanding their 'advanced' country status, Ireland and Spain continue to occupy a position within the NIDL on the basis of the differentiated and relativised development of the productive subjectivity of their working class, and therefore allow us to cast fresh light on the dynamics of development, capital accumulation, and crisis outside of the 'late industrialising' states of Latin America and Southeast Asia. Finally, South Korea stands out as the country which, in the past, has been used to undermine the original NIDL thesis since its 'take-off' is often said to be the exception that disproves the rule of that thesis (as formulated by Fröbel, Heinrichs, and Kreye, of course).

The book begins with a chapter originally published in Spanish, which introduces Juan Iñigo Carrera's take on the NIDL. In it, Iñigo Carrera proceeds from a particular point of departure, that is, from the *global process* of accumulation in its organic unity, and within which distinct national processes of accumulation emerge as specific concrete forms of that same global process. He argues that there is an objective determination relating to the formation of a general rate of profit as the regulator of the unity of the process of capital accumulation, and which engenders a qualitative difference between those capitals that are able to contribute to that formation and those which cannot—resulting therefore in differentiated concrete rates of profit. The latter sections of the chapter integrate these two arguments so as to present an innovative, critical, methodological basis for the re-examination of the CIDL and NIDL—one that sharply contrasts with dominant interpretations.[6]

In Chap. 3, Gastón Caligaris provides fresh insight into the old, or classical, international division of labour and into the development of capitalism in resource-rich countries whose longstanding historical role in the world market has been to produce ground-rent-bearing commodities. The chapter builds, again, upon the notion of capital accumulation as being global in content and national in form. From this perspective Caligaris challenges a dominant perspective that explains the functioning of a national economy as the result of domestic politics, and another that explains it as a consequence of foreign influence and domination. He instead presents an original approach that explains the specific characteristics of the national process of accumulation in countries specialised in the production of ground-rent-bearing commodities, and in doing so substantiates the argument that ground-rent is essentially constituted by the surplus-value resulting from the valorisation of industrial capitals abroad and which flows into 'resource rich', raw materials-producing countries. The chapter therefore further advances the critique of those approaches that attempt to explain such characteristics through theories and analyses of unequal exchange with advanced capitalist countries. The latter sections of the chapter use empirical evidence from the example of capitalist development in Argentina during the twentieth century to illustrate the core argument.

In Chap. 4, Guido Starosta turns his attention to the task of the critical reconstruction of the NIDL thesis. While acknowledging the insights of the original thesis, Starosta argues that the foundation for the emergence of the NIDL does not reside in the intensification of the manufacturing division of labour, that is, in the deskilling resulting from the subdivision of the production process into elements. Instead, the NIDL developed as an expression of the impact that the progress of the automation of capitalist large-scale industry has had on the individual and collective productive subjectivity of the working class. More specifically, the constitution of the NIDL has been the result of the transformation of the modes of existence of the global collective labourer, brought about by the leap forward in the process of computerisation and robotisation of the production processes of large-scale industry, especially since the 'microelectronics revolution'. As a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class. Each national sphere of accumulation therefore tends to concentrate a certain type of labour-power of distinctive material and moral productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner. Production in specific industrial sectors has thereby expanded in some countries, while contracting in others where new and more advanced sectors developed, following a rhythm determined by the evolution of those two main factors—i.e. technological change and the relative cost and productive attributes of national labour forces. An important claim made by this chapter, therefore, and which subsequently has relevance for Chaps. 5 and 9, concerns the degree to which structural characteristics of the CIDL and the NIDL today co-exist in national spaces of accumulation—particularly in Latin America. This, the chapter concludes, actually confirms the validity of a reworked NIDL thesis rather than its unequivocal refutation.

Part II turns to national case studies of capitalist development within the international division of labour. In Chap. 5, Thomas Purcell scrutinises the experiences of two countries whose national governments have been said to be representative of 'post-neoliberalism', Ecuador and Venezuela. Taking his cue from Part I, Purcell argues that the CIDL was never simply reducible to the polarisation of an industrialised core and a dependent periphery, with the latter restricted to the role of supplier of raw materials and staple foods. Rather, there was an important process of accumulation in the periphery, whereby national industrial capital was able to valorise through the appropriation of inflows of ground-rent; a process which today also points towards the continuation of elements of the classic within the new IDL. The global rise in primary commodity prices in recent years has put the question of the use of income from natural resources for developmental goals back on the political agenda across Latin America. Drawing upon Iñigo Carrera (2007), Purcell examines the distinction between agricultural and mining landownership in the context of global transformation associated with the international division of labour, so as to explain the developmental trajectories of Ecuador and Venezuela. He argues that dual landlordism in Ecuador—in the form of an agro-export elite and a state-controlled oil sector—contrasts with the singular dominance of the state-controlled oil sector in Venezuela, and this, for Purcell, explains the manner in which the two national forms of insertion into the international division of labour have determined different national variants of post-neoliberalism.

Chapter 6 examines Ireland's rapid structural economic transformation during the 1990s, and the debates that emerged about the potentialities and limits of this idiosyncratic 'developmental model', and its apparently successful integration into the global economy. Whilst neo-liberal economists have tended to explain the Irish experience of rapid growth in terms of the adoption of a liberalisation and export-led strategy that opened the economy to vast inflows of 'high-tech' FDI (foreign direct investment), critical commentators have argued that such an account ignores the active role actually played by the Irish state and related institutions and organisations in shaping the precise mode in which the 'local' economy integrated into 'globalised networks' of high-tech production and innovation. According to this alternative view, the Irish case is actually that of a Network Developmental State that manages the connection between the local and the global and, through its active involvement in industrial development, steers the national economy along a path of integration into the technologically most dynamic elements of the world economy. In contrast to the authoritarian state developmentalism of the East Asian Tigers, and their (initial) reliance on the 'super-exploitation' of cheap manual labour, the Celtic Tiger model would be predicated on democratic institutions and more qualified, higher-wage jobs in cutting-edge sectors of the economy. Tomás Friedenthal and Guido Starosta take issue with these apparently opposed explanations insofar as they both explain the trajectory of the Irish developmental process on the basis of the successful implementation of 'correct' nation-state policies (even if they disagree on the precise nature of those policies). By contrast, this chapter argues that the Irish experience is yet another concrete expression of the further development of the essentially *global* dynamics of the NIDL. More specifically, it argues that the continuous skill-replacing technical change characterising the production of relative surplus-value across the globe has allowed capital to integrate national working classes with more skilled, but still relatively cheaper, labour-power into the NIDL. The peculiar state policies and institutions prevailing in Ireland are therefore grounded in this specific form of integration into the NIDL.

In Chap. 7, Greig Charnock, Thomas Purcell, and Ramon Ribera-Fumaz focus on the case of Spain in support of Iñigo Carrera's argument that, as a result of the general crisis of overproduction, the marked differentiation in the conditions of reproduction and exploitation of the working class *within* national borders since the 1970s has unfolded through a form of differentiated integration in Europe. Charnock, Purcell, and Ribera-Fumaz argue that it is crucially important to understand the longer-term historical role played within the NIDL by relatively late-industrialising countries that are today bearing the brunt of crisis and internal devaluation in a 'unified' Europe. Focusing on Spain, they argue that it is precisely on the material basis of its full integration within the NIDL from the mid-1970s that the conditions of the reproduction of the working class were reshaped, and it is this historical component in the reproduction of the Spanish accumulation process that has prefigured the process of the differentiation of the conditions of the reproduction of the working class across *and* within its borders ever since.

In Part III, we turn to specific sectoral case studies within the NIDL. The choice of case studies is again not arbitrary, since the automotive and steel production sectors have been at the historical vanguard of the move towards the NIDL, and they have been industries in which the actual determinants of the NIDL, which the book seeks to identify, have been most visible. In Chap. 8, Alejandro Fitzsimons and Sebastián Guevara examine the historical development of the Argentine automotive industry from the mid-1950s to the present. They argue first that the peculiar characteristics of low scales of production, obsolete technology, and the resulting low global competitiveness of the local auto industry in its initial stages were determined by the specific form of capital accumulation prevailing in Argentina as a result of its participation in the CIDL. This specificity had at its core the process of appropriation by industrial capital of a portion of the relatively abundant ground-rent available in Argentina; in this case, by transnational automotive manufacturers. Challenging the dominant point of view that the development of the NIDL led to the qualitative restructuring of the Argentinean automotive industry, this chapter examines concrete changes within the labour process and forms of valorisation of capital in the industry. In so doing the chapter argues that, despite these changes, the automotive industry in fact continued its development on the same basis as before—i.e. the appropriation by TNCs of a portion of agrarian ground-rent. Fitzsimons and Guevara conclude, therefore, that the NIDL did not 'restructure' the Argentine automotive industry—as is commonly claimed.

In Chap. 9, Nicolas Grinberg offers an alternative account to the mainstream, institutionalist view on the state-led process of economic development in Brazil and South Korea. Focusing on the development of the Brazilian and Korean steel industries, Grinberg claims that the specific form of participation of each economy in the production of relative surplus-value on a global scale has determined both the pattern of industrialisation that followed, and the political processes through which it came about. In Brazil, industrial capital has accumulated through the state-mediated recovery of ground-rent, which has implied small-scale production for protected domestic markets. By contrast, in South Korea industrial capital has accumulated through the exploitation of a relatively cheap and disciplined workforce performing simplified activities for world market production in increasingly complex sectors. The significance of Grinberg's analysis for us is that, while South Korea's 'take-off' is often used to refute the original NIDL thesis, the Korean case actually vindicates the revised version of the NIDL thesis put forward by this book.

NOTES

1. See, for example, Iñigo Carrera (2006, 2013, 2014, 2015). Several of Iñigo Carrera's other working papers are available in English through the CICP web site: http://www.cicpint.org/CICP%20English/Principal.html.
2. The productive attributes of workers include the strictly material or technical dimension of labour-power required by the particularity and complexity of the productive functions to be performed, as well as its 'moral' attributes (that is, the general forms of consciousness and self-understandings that make those workers suitable for the specific forms of discipline that a certain organisation of the capitalist labour process entails). The term 'productive subjectivity' captures this twofold dimension of labour-power.
3. As Radice (2009: 29) summarises, 'the mechanism through which this unequal distribution of rewards is sustained is, in essence, that of market structure: businesses and zones engaging in core activities have market power based on superior technology, management and access to finance, while those engaging in peripheral activities have only generic resources of cheap land and unskilled labour, the markets for which are highly competitive.'
4. All three of these frameworks/concepts figure in the selection of articles edited by Bruff and Ebenau (2014). See Rioux (2015) for a critical discussion of Trotsky's notion of 'uneven and combined development', and for a thorough critique of the (failed) attempt to come up with 'a social theory of the international' in the work of Justin Rosenberg and others.
5. It ought to be self-evident from the foregoing outline of the approach taken in this book that a focus on country case studies does not imply a crude

methodological nationalism on our part. But to clarify, Part II focuses on countries for two reasons: first, because even if it is a mediating form and not a self-subsistent content, the national form is real and objective, and it is actually by exacerbating national differentiation that the global content of the NIDL unfolds; and it allows us to show that it is impossible to explain national dynamics as if they were autonomous from the global content of accumulation.

6. An appendix to Chap. 2, which we have been unable to reproduce in this book due to space constraints, is available at: https://www.academia.edu/24332230/End_Notes_to_The_general_rate_of_profit_and_its_realisation_in_the_differentiation_of_industrial_capitals_1?auto=download. In it, Iñigo Carrera confronts two crucial problems: first, the asymmetric relation between national economies of markedly distinct structures; and, second, the asymmetric relation between capitals of very distinct accumulation capacities within the same value chain. Until now, the first question has been approached by means of theories of development and underdevelopment, imperialism, unequal exchange, dependency, and so on. Iñigo Carrera asserts that these theories all conceive of national processes of accumulation as being essentially autonomous. The second question of the asymmetric relation within value chains has, until now, been explained by theories of imperfect competition and of monopoly capital. Both theories agree that such asymmetry results from the behaviour of key agents. Therefore both theories erroneously eschew the existence of objective determinations that regulate social production and consumption through the formation of a general rate of profit.

The System of Machinery and Determinations of Revolutionary Subjectivity in the *Grundrisse* and *Capital*[1]

Guido Starosta

This chapter proposes a reading of Marx's exposition of the forms of the real subsumption of labour to capital – in particular, the system of machinery of large-scale industry – as constituting the dialectical presentation of the determinations of revolutionary subjectivity. The proposition that the real subsumption constitutes the ground of revolutionary subjectivity should come as no surprise. In reality, this is no more than the concretisation of that insight about the most general determination of the process of 'natural history' constituting the development of humanity that Marx expounded in the Paris manuscripts of 1844. According to that early text, the content of the history of the human species consists in the development of the specific material powers of the human being as a working subject, that is, of *human productive subjectivity*. It is in the historical transformation of its material and social forms, Marx concluded, that the key to the abolition of capital – hence, to revolutionary subjectivity – should reside. However, that early attempt at the critique of political economy could not offer a rigorous scientific comprehension of the social determinations underlying the revolutionary transformation of society. Armed with a Feuerbach-inspired method of transformative criticism, Marx managed *analytically* to uncover alienated labour as the hidden *social* foundation behind the reified objectivity of 'economic categories'. In turn, in those early writings he analytically discovered the specificity of the human species-being (i.e., human productive subjectivity) as the *material* content historically developing in that alienated form. However, although these discoveries allowed Marx to grasp the *simplest* (human) determination behind the content and form of the abolition of alienated labour, he arguably failed at *synthetically* unfolding the further mediations entailed by the social and material constitution of the revolutionary subject.[2]

---

[1] A shorter version of this paper has appeared in *Science & Society* 75, 1, 2011.

The theoretico-practical need for the further dialectical development of the critique of political economy, which would eventually lead Marx to write *Capital*, expresses the following fact. The immanent ground of revolutionary subjectivity is not simple and unmediated; for instance, the sheer general materiality of human productive practice as the negated content behind the alienated objectivity of capitalist social forms.[3] Instead, it is a 'unity of many determinations', which therefore means that its scientific comprehension can only be the result of a complex dialectical investigation involving both the analytic movement from the concrete to the abstract and the synthetic, mediated return to the concrete starting point.[4] Dialectical research must therefore analytically apprehend all relevant social forms and synthetically reproduce the 'inner connections' leading to the constitution of the political action of wage-labourers as the form taken by the revolutionary transformation of the historical mode of existence of the human life-process.

Now, as the title of Marx's most important work denotes, the subject whose determinations the dialectical investigation proceeds to discover and present is *capital*, which, as the alienated subject of social life, becomes 'the all-dominating economic power of bourgeois society' and must therefore 'form the starting-point as well as the finishing-point' of the ideal reproduction of the concrete.[5] This does not leave revolutionary subjectivity outside the scope of the dialectical unfolding of capitalist social forms. Rather, it means that revolutionary subjectivity itself must be comprehended as the realisation of an immanent determination of capital as alienated subject.[6] Accordingly, its dialectical *presentation* must essentially consist in the *synthetic* unfolding of the contradictory movement between materiality and capital-form up to its absolute limit, revealing the proletariat's self-abolishing action as the necessary form in which the former content asserts itself.[7]

[6] This point was insightfully hinted at in the 1970s by Giacomo Marramao in his critical appraisal of the polemic between the more subjectivist positions of Korsch and the Dutch Left Communists (Pannekoek, Gorter) and the objectivism of defenders of the theory of capitalist breakdown (Mattick, Grossmann). See Marramao 1975/6, pp. 152–5, and 1982, pp. 139–43. At least formally, Marramao correctly highlighted the necessity to ground the genesis of class-consciousness 'in terms of the process of production and

It was fundamentally in *Capital* (but, crucially, also in the *Grundrisse*), mainly through the exposition of the determinations of the different forms of production of relative surplus-value (hence of the real subsumption of labour to capital), where Marx managed to concretise the systematic dialectic of alienated human labour. He did this by showing precisely what the capital-form does to the materiality of human productive subjectivity as it takes possession of, and transforms, the labour-process. Seen externally, the implicit concrete question under investigation was the following: does capital transform human productive subjectivity in a way that eventually equips the latter with the material powers to transcend its alienated social form of development? From this materialist standpoint, only if this were the case would it make sense to pose the question of conscious revolutionary action as a concrete objective potentiality immanent in capitalist society.[8] In other words, Marx's point was the need to discover the material determinations of communist society in their present mode of existence as an *alienated potentiality* engendered by the autonomised movement of the capital-form to be realised – that is, turned into *actuality* – precisely and necessarily through the conscious revolutionary action of the self-abolishing proletariat.

Those determinations appear scattered and are just mentioned in passing in several of Marx's texts. They all characterise the simplest defining character of communism as the fully self-conscious organisation of social labour as a collective potency by the thereby freely associated producers. It is in the *Grundrisse*, in the context of the critique of Adam Smith's conception of labour as sacrifice, that Marx offers the clearest and most concise characterisation of the general attributes of what he calls 'really free working':

> The work of material production can achieve this character [as 'really free working', GS] only (1) when its social character is posited, (2) when it is of

---

reproduction', that is, within the 'objectivity of social relations' and their (autonomised) self-movement. In other words, Marramao clearly saw the necessity to establish a firm connection between the critique of political economy and the 'theory of revolution'. More recently, the point about need to find the immanent ground of emancipatory subjectivity in the contradictory unfolding of the reified forms of social mediation of capitalist society has been forcefully made by Postone 1993, although his own attempt is not without weaknesses. See Starosta 2004.

7. For an elaboration of the methodological underpinnings of this point, see Iñigo Carrera's chapter in this book.

8. Marx 1993, p. 159.

> a scientific and at the same time general character, not merely human exertion as a specifically harnessed natural force, but exertion as subject, which appears in the production process not in a merely natural, spontaneous form, but as an activity regulating all the forces of nature.[9]

The interesting and 'intriguing' aspect of this passage is that Marx not only claims that in order to be really free, labour must become a consciously organised, directly social activity, but also that the consciousness regulating that emancipated productive activity must be of a *general* and *scientific* kind. As we shall see later, this latter attribute, scarcely mentioned by Marx on other occasions,[10] will prove of paramount importance for our comprehension of the concrete determinations of revolutionary subjectivity; a task that Marx himself achieved, although not without tensions and ambiguities. At this stage, I would just like to reformulate the question of the relation between capital and productive subjectivity posed above in the light of that passage from the *Grundrisse*. Does the development of capital transform human productive subjectivity in such a way as to engender the necessity of producing the latter with the two general attributes mentioned by Marx? Furthermore, is the working class the material subject bearing them?

In this paper, then, I discuss the way in which Marx, through the dialectical exposition of the contradictory movement of the real subsumption, actually presented the genesis of the revolutionary subject. The argument is firstly developed through a close reading of Marx's discussion of the determinations of large-scale industry in *Capital*, as the latter constitutes the most developed form of real subsumption. The essence of this capitalist transformation of the production-process of human life lies in the mutation of the productive attributes of the collective labourer according to a determinate tendency: the individual organs of the latter eventually become *universal productive subjects*. This is the inner *material* determination underlying the *political* revolutionary subjectivity of the proletariat. However, I argue that Marx's dialectical exposition of those transformations in *Capital* is in some respects truncated and does not unfold the plenitude of the material determinations underlying the revolutionary existence of the working class. The latter is presented as no more than an abstract possibility. A gap therefore remains between the 'dialectic of alienated human labour' unfolded in the chapters on relative surplus-value in *Capital*, and the revolutionary conclusions at the end of Volume I in the chapter on 'The Historical Tendency of Capital Accumulation'. The paper finally suggests that the so-called 'Fragment on machines' from the *Grundrisse* contains a different but complementary perspective on the productive subjectivity characteristic of large-scale industry. Through a careful reading of the relevant passages of that earlier version of the critique of political economy, it is possible to undertake the completion of the systematic unfolding of the social and material determinations of revolutionary subjectivity.

---

[9] Marx 1993, pp. 611–12.

[10] See, however, Marx's remarks in the *Paris Manuscripts* on the need for the constitution of 'natural science of man' or 'human natural science' as the basis for emancipated human practice. Marx 1992b, p. 355.

Large-scale industry and workers' productive subjectivity in *Capital*

The guiding thread running through Marx's exposition of the concrete forms of the production of relative surplus-value resides in the revolutions to which capital subjects the productive subjectivity of the doubly free labourer as the means for the multiplication of its power of self-valorisation. However, it is not there that Marx's presentation of the determinations of large-scale industry begins. The reason for this derives from the very starting point of the production of relative surplus-value through the system of machinery that characterises large-scale industry. As Marx points out, if in manufacture the point of departure of the transformation of the material conditions of social labour was productive subjectivity as such (with the transformation of the instrument of labour, in the form of a specialisation, determined as a result of the former), in large-scale industry the transformation of the instrument of labour constitutes the starting point, the transformation of the wage-labourer being its result.[11]

Marx presents the essence of this transformation of the human labour-process by developing the specific materiality of machinery, in particular *vis-à-vis* the labour-process in manufacture. In reality, the simplest determination of that difference was already anticipated by Marx in the transition contained in the previous chapter of *Capital*, where the necessity of the development of machinery was laid bare. I am referring to capital's need to do away with the subjective basis of manufacture through the development of an 'objective framework' for material production, independent of the manual expertise and immediate practical knowledge of workers. In brief, it is about giving an objective form to the powers of social labour springing from direct productive co-operation.[12]

The two-fold material specificity of the machine thereby springs from the objectification of both the – however restricted – knowledge and manual skills and strength of the manufacturing labourer. On the one hand, capital strives to substitute the movement of the forces of nature for that of the human hand as the immediate agent in the transformation of the object of labour into a new use-value. On the other hand, it attempts to displace the immediate subjective experience of the worker as the basis for the conscious regulation of the labour-process, that is, as the basis for knowledge of the determinations of the latter. This implies, in the first place, the need to turn the production of that knowledge into an activity which, whilst clearly remaining an inner moment of the organisation of social labour, nonetheless acquires a differentiated existence from the immediacy of the direct production-process. Coupled with the need to objectify it as a productive power directly borne by the 'dead labour' represented in the machine, that knowledge must necessarily take the general form of *science*.[13] Capital thereby advances, for the first time in human (pre)history, in the generalisation of the application of science as an immediate potency of the direct production-process.[14] Note, however, that at this stage of the exposition scientific knowledge does not appear directly as productive activity but only as already objectified in the form of the machine, that is, simply as a presupposition for the latter's existence.

---

[11] Marx 1976a, p. 492.

[12] Marx 1976a, pp. 490–1.

Thus far, these are the fundamental aspects of Marx's exposition of the *material* specificity of the production-process of capital based on the system of machinery, i.e., the transformations it suffers in its aspect as a process of production of use-values. However, the process of production of capital is such for being the unity of the labour-process and the valorisation-process. Hence, Marx's presentation goes on to develop the specific impact of the system of machinery on the conditions for value's self-expansion, on the *form-determinations* of the production-process of capital.[15] With this, Marx's presentation exhausts the novel determinations brought about by the system of machinery to the production-process as they pertain to its 'objective factor'. What necessarily follows, then, is the investigation of the impact of these transformations on the 'subjective factor' of the labour-process, that is, on the worker.

In the third section of the chapter on large-scale industry, Marx initially presents what he refers to as only 'some general effects' of the system of machinery on the worker, that is, those changes that can be discussed without developing the specific form in which the 'human material is incorporated with this objective organism'.[16] In other words, these are the effects whose development does not involve any new *qualitative* determination in the productive subjectivity of workers. Rather, they refer to the *quantitative* changes that machinery brings about in capital's valorisation-process as a process of exploitation of living labour. These include: the quantitative extension of the mass of exploitable labour-power through the incorporation of female and child-labour; the tendency to prolong the working day; and the tendency to increase the intensive magnitude of the exploitation of human labour.

---

[13] Marx 1976a, p. 508.
[14] Marx 1994, p. 32.
[15] Marx 1976a, pp. 508–17.
[16] Marx 1976a, p. 517.

It is in section four, through the presentation of the functioning of 'the factory as a whole', that Marx starts to unfold the specific *qualitative* determinations of the productive subjectivity of large-scale industry. The discussion of a passage from Ure serves Marx succinctly to identify the most general determination of the factory as the sphere of capitalist society where the conscious regulation of an immediately social production-process takes place. A conscious regulation, however, that is determined as a concrete form of the *inverted general social regulation* as an attribute of the materialised social relation in its process of self-expansion. In the factory – and this is the issue that Ure's definition overlooks – this inverted social existence reaches a further stage in its development by acquiring a 'technical and palpable reality'.[17]

Thus, the scientific conscious regulation of social labour characterising large-scale industry is not an attribute borne by those workers performing direct labour in the immediate production-process. For them, those powers exist already objectified in the system of machinery, to whose automatic movement they have to subordinate the exercise of their productive consciousness and will, to the point of becoming 'its living appendages'.[18] Large-scale industry consequently entails an enormous scientific development of the 'intellectual faculties of the production process' only by exacerbating their separation from direct labourers. In its mode of existence as a system of machinery, the product of labour comes to dominate the worker in the direct process of production not only formally but even materially as well. Capital thus appears to those workers as the *concrete material subject* of the production-process itself.

With all these elements, we can now turn to summarise the specific determination of the productive subjectivity of the worker of large-scale industry. In (*tendentially*) doing away with the need for all specialised skill and knowledge of workers, the production of relative surplus-value through the system of machinery gives the development of their productive subjectivity the concrete form of an *absolute degradation*. In this brutal way, and in opposition to the *particularism* of the subjectivity of the wage-labourer of manufacture, large-scale industry begets, as its most genuine product, a *universal worker*, that is, a productive subject capable of taking part in any form of the human labour-process. In the words of Marx:

> Hence, in place of the hierarchy of specialised workers that characterizes manufacture, there appears, in the automatic factory, a *tendency* to equalize

---

[17] Marx 1976a, p. 548.
[18] Ibid.

> and reduce to an identical level every kind of work that has to be done by the minders of the machines; in place of the artificially produced distinctions between the specialized workers, it is natural differences of age and sex that predominate.[19]

With this tendency to the production of workers who are capable of working with any machine, the simple material or technical necessity for the life-long attachment of individuals to a single productive function disappears.[20] However, insofar as machines become specialised into certain particular productive functions, the persistence of the division of labour in the factory is still technically *possible*. Indeed, Marx argues, the exploitative relation between capitalists and workers that mediates the development of the material productive forces of social labour as an alienated attribute of its product, leads to the reproduction of the 'old division of labour' in an even more hideous fashion.[21] Large-scale industry's tendency to produce an increasingly universal worker is thereby realised in the concrete form of its negation, that is, by multiplying the spaces for the exploitation of living labour on the basis of an exacerbation of 'ossified particularities'. Thus, the individual capitalist could not care less about the disappearance of the technical necessity for a particularistic development of the worker's productive subjectivity. Under the pressure of competition, his/her only individual motive is the production of an extra surplus-value. If he/she can obtain it by attaching the worker to 'the lifelong speciality of serving the same machine',[22] so he/she will. In effect, the reproduction of the division of labour under the new technical conditions implies that a lower value of labour-power can be paid – since 'the expenses necessary for his [the workers', GS] reproduction' are 'considerably lessened'. In addition, it implies that a greater docility on the part of the exploitable human material is induced – since 'his helpless dependence upon the factory as a whole, and therefore upon the capitalist, is rendered complete'.[23]

It is crucial, at this juncture, to be clear about this contradictory movement between universality and particularity of the determinations of the productive subjectivity of large-scale industry. Paraphrasing Marx, here, as everywhere else, we must distinguish between the general tendency of capital-accumulation and the concrete forms in which the essence of the historical movement is realised. *Thus, the essential determination which, as we shall see, expresses the reason to be of the capitalist mode of production, lies in the tendency to universalise the productive attributes of wage-labourers*. This is the general movement of the production of relative surplus-value through the system of machinery which underlies – hence, gives unity to – the variegated forms that the labour-process presents in the course of capitalist development. In order to substantiate this, let us now move ahead in our reading of Marx's investigation of large-scale industry to the point in *Capital* where he further unfolds the movement of the identified contradiction, that is, to the subsequent discussion of factory-legislation in section nine of this same chapter.[24]

---

[19] Marx 1976a, p. 545, my emphasis.
[20] Marx 1976a, p. 546.
[21] Marx 1976a, p. 547.
[22] Ibid.
[23] Ibid.

The crucial point for our argument is that section nine completes (as far as *Capital* is concerned) the development of the specific determinations of the productive subjectivity of large-scale industry. In effect, Marx's exposition in section four had left the dialectical presentation with an unresolved contradiction between large-scale industry's general tendency for universality and the exacerbation of the particularism of the division of labour that, left to the unrestrained will of individual capitalists, it allowed. In addition, we shall see how this discussion leads Marx, for the first time in his dialectical exposition, to uncover the revolutionary historical potentialities carried by this specifically capitalist form of human labour-power.

---

[24] In my view, Marx's presentation is not fully clear and consistent in distinguishing between essential determination (and therefore general tendency) and concrete form in which it is realised. This lack of clarity probably stems from the uneasy co-existence of systematic and historical moments in the exposition. Thus, he firstly presents the general determination of the productive subjectivity of large-scale industry (namely, its universality) 'in its purity', without necessarily implying that it has been fully realised in its historical concrete forms. However, in his subsequent empirical illustrations he seems to treat the general determination as an immediate actuality. He therefore posits the persistence of the particularistic development of productive subjectivity as '*artificially*' reproduced by superimposing the division of labour where its technical necessity has actually disappeared. See Marx 1976a, pp. 546–7, where he remarks that the insignificance of 'on-the-job' skills required for machine-work has done away with the need to bring up a special kind of worker and that the attachment of the worker to a single specialised machine represents a 'misuse' of the latter. While this might have been more or less the case in the particular industries that he discusses, this was by no means the general situation of large-scale industry in his time. The general tendency for a universal productive subjectivity is realised only *gradually* in the historical course of capital-development. In this sense, the technical necessity for particularistic attributes of labour-power is not done away with overnight. Without a doubt, the historical development of large-scale industry registers a tendency for the degradation of experienced-based ('tacit') knowledge of the determinations of the labour-process. However, the progress of capitalist automation has so far involved the recreation of the technical necessity for certain (albeit increasingly more limited) particularistic development of productive subjectivity. Thus, even during the so-called 'Fordist' cycle of accumulation, the full mastery of machines required a relatively lengthy learning process achieved by flanking a skilled operator. Only with the more recent wave of computer-based automation have particularistic or experienced-based skills significantly lost their former centrality (without, however, fully disappearing). On these recent transformations in the labour-process, see Balconi 2002.

The movement of 'the contradiction between the division of labour under manufacture and the essential character of large-scale industry'[25] acquires a first expression in the establishment of compulsory elementary education for working children. As Marx points out, the unchecked exploitation of child-labour by individual capitals led not only to the 'physical deterioration of children and young persons',[26] but also to an artificially-produced intellectual degeneration, which transformed 'immature human beings into mere machines for the production of relative surplus-value'.[27] Since 'there is a very clear distinction between this and the state of natural ignorance in which the mind lies fallow without loosing its capacity for development, its natural fertility',[28] these excesses of the capitalist exploitation of child labour-power eventually reacted back on the very capacity of valorisation of total social capital by jeopardising the existence of the future generation of adult-workers in the 'material and moral conditions' needed by capital-accumulation itself. This is illustrated by Marx through a discussion of the case of the English letter-press printing trade, which, before the introduction of the printing machine, was organised around a system of apprenticeship in which workers 'went through a course of teaching till they were finished printers' and according to which 'to be able to read and write was for every one of them a requirement of their trade'.[29] With the introduction of printing machines, however, capitalists were allowed to hire children from 11 to 17 years of age, who 'in a great proportion cannot read' and 'are, as a rule, utter savages and very extraordinary creatures'.[30] These young workers were day after day attached to the simplest of tasks for very long hours until being 'discharged from the printing establishments' for having become 'too old for such children's work'.[31] Those 17-year-old workers were left in such intellectual and physical degradation that they were unfit to provide capital, *even in the same factory*, with the miserably restricted productive attributes that it required from its immediate source of surplus-value, namely, human labour-power.

The education-clauses of the factory-legislation allow Marx not only to dispel any doubt about capital's 'universal vocation' in its transformation of human productive subjectivity. They also serve to highlight, for the first time in his whole dialectical exposition, that it is *only* the development of *that* specific form of human productive subjectivity that expresses capital's historic movement in the production of the material powers for its own supersession as the general social relation regulating human life:

> As Robert Owen has shown us in detail, the germ of the education of the future is present in the factory system; this education will, in the case of every child over a given age, combine productive labour with instruction and gymnastics, not only as one of the methods of adding to the efficiency of production, but as the only method of producing fully developed human beings.[32]

Notice, however, that Marx makes clear that the education-clauses represent the *germ* – and just that – of the 'education of the future'. To put it differently, Marx's discussion aims at showing *both* that the social forms of the future are effectively carried as a potentiality by the productive subjectivity of large-scale industry under consideration *and* that, with the determinations unfolded so far, this potentiality is not yet immediate. On the contrary, in their 'paltriness', the education-clauses reveal that these determinations are far from being a 'method of producing fully developed human beings'. Rather, they are forms of positing individuals whose productive subjectivity is still trapped within the miserable forms imposed by the reproduction of the conditions for capital's valorisation. Other material transformations are still needed to mediate the development of those germinal elements into their plenitude.

The total social capital's necessity to produce universal workers is not exhausted by the obstacles to its valorisation posed by the division of labour within the workshop. As Marx remarks, 'what is true of the division of labour within the workshop under the system of manufacture is also true of the division of labour within society'.[33] In effect, inasmuch as the technical basis of large-scale industry is essentially revolutionary, it entails the permanent transformation of the material conditions of social labour and, therefore, of the forms of exertion of the productive subjectivity of individual workers and of their articulation as a directly collective productive body.[34] This continuous technical change thereby requires individuals who can work in the ever-renewed material forms of the production of relative surplus-value. 'Thus', Marx concludes, 'large-scale industry, by its very nature, necessitates variation of labour, fluidity of functions, and mobility of the worker in all directions'.[35] However, he also points out again how the general organisation of social production through the valorisation of independent fragments of social capital negates the immediate realisation of this tendency for an all-sided development of individuals.[36] The private fragmentation of social labour, and its reified social mediation through the capital-form, permits the reproduction of 'the old division of labour with its ossified particularities'.[37] Thus it gives the imposition of variation of labour the form of 'an overpowering natural law, and with the blindly destructive action of a natural law that meets with obstacles everywhere'.[38] In this contradictory form, the realisation of large-scale industry's tendency to produce universal workers nonetheless marches forward, also revealing that it is in the full development of this determination that this alienated social form finds its own *absolute limit*.[39] In other words, that it is on the fully-expanded universal character of human productive subjectivity that the *material basis* for the new society rests.

[32] Marx 1976a, p. 614.
[33] Marx 1976a, p. 615.
[34] Marx 1976a, p. 617.
[35] Ibid.
[36] See Bellofiore 1998a, for suggestive reflections on this question.

> This possibility of varying labour must become a general law of social production, and the existing relations must be adapted to permit its realization in practice ... the partially developed individual, who is merely the bearer of one specialised social function, must be replaced by the totally developed individual, for whom the different social functions are different modes of activity he takes up in turn.[40]

With this discussion Marx unfolds the way in which the general necessities of the reproduction of the total social capital – in this case, workers bearing a universal productive subjectivity – clashes with its concrete realisation through the private actions of individual capitals (which strive for the perpetuation and exacerbation of the particularistic development of productive subjectivity). Moreover, we see how this contradiction moves by determining the working class as the personification of the mediated necessities of the valorisation of capital, the latter providing the material and social foundation for proletarian political power.[41] In effect, the development of large-scale industry makes the possession of a universal subjectivity a matter of survival for the members of the working class since, as evidenced by the aforementioned case of the printing-trade workers, only in that way can they be in a position to sell their labour-power to capital (thereby turning the alienated necessities of social capital into an immediate need for their social and material reproduction). Thus, workers have to 'put their heads together' again and, through their struggle as a class, force the capitalist state to 'proclaim that elementary education is a compulsory pre-condition for the employment of children'.[42] But what is elementary education if not a – certainly very basic – step in the formation of future *universal workers*? That is, in the development of productive attributes that equips the labourer to work not in this or that particular aspect of the immediately social labour-process of the collective labourer of large-scale industry, but in whatever task that capital requires from him or her?[43]

[39] Marx 1976a, p. 617.

[40] Marx 1976a, p. 618.

[41] By 'mediated necessities', I denote those that are a moment of the production of surplus-value, but that are antithetical to the simplest (hence immediate) necessity of self-valorising value to increase its magnitude by any means personified by individual capitals. Although a proper discussion of this essential point exceeds the scope of this chapter, I think that this discussion illustrates the way in which Marx sees the systematic connection between capital-accumulation and class-struggle. Specifically, Marx presents the class-struggle as the most general *direct* social relation through which the *indirect* relations of capitalist production assert themselves. On this point, see Iñigo Carrera 2003, pp. 5–6. Whilst this certainly means that class-antagonism is an endemic reality of capitalist production, it also means that it is not the self-moving content behind its development (as argued, for example, by Bonefeld 1995). Moreover, neither does its simple existence as such immediately express the emergence of an antagonistic principle of organisation of social life other than the valorisation of capital, which would be, in turn, incarnated in the working class (as in the so-called 'Autonomist Marxist' approach; see Cleaver 1992 and De Angelis 1995). Instead, the systematic place of the class-struggle as a social form shows that the production of surplus-value is a potentiality of

Social capital's need for universal workers thereby provides another material basis for the political power of the working class in its confrontation with the capitalist class over the conditions of its social reproduction. In this first expression of that relation between large-scale industry and workers' power represented by the Factory-Acts, the class-struggle does not appear to transcend its most general determination as the form of the buying/selling of the commodity labour-power at its value, which Marx unfolds in Chapter ten on 'The working day'.[44] Yet Marx advances the proposition that, when concretely developed, that tendency towards universal productive subjectivity will eventually provide the

---

the alienated movement of social labour *in its unity*. In other words, Marx's exposition of the social form of class-struggle makes evident that the concrete subject of the process of valorisation – and hence of the movement of alienated social reproduction – is the *total social capital*. Compare Starosta 2005, Chapter Five. This does not imply the denial of the transformative powers of human practice personified by the workers. What this does imply is that whatever transformative powers the political action of workers might have – *both* capital-reproducing *and* capital-transcending political action – must be an immanent determination begotten by the alienated movement of capital as subject and not external to it.

[42] Marx 1976a, p. 613.

[43] Recent historical developments of machine-based production have confirmed the general tendency identified by Marx: degradation of particularistic productive attributes developed on the job, coupled with expansion of the requirements of formal education to produce its more *universal* dimensions. The latter is the necessary prerequisite for the constitution of the more general and abstract knowledge that the contemporary operator of computer-based technologies sets into motion vis-à-vis the 'Fordist' machinist ('controlling' the carrying out of a task rather than actually 'doing' it). See Balconi 2002.

[44] See Kicillof and Starosta 2007a and 2007b; Iñigo Carrera 2003, pp. 81–2, and Müller and Neusüss 1975.

class-struggle with expanded transformative powers, namely, those necessary for the establishment of the workers' 'political supremacy' as a class.[45]

Now, the question immediately arises as to what are the more concrete determinations behind this inevitability of the proletarian conquest of political power? Unfortunately, Marx provides no answer in these pages. In fact, one could argue that no answer could have been provided at all. The unfolding of the necessity of 'proletarian dictatorship' as a concrete social form involves still more mediations and, therefore, the former is not carried by the social form we are facing at this point of the exposition in the form of an *immediate potentiality* to be realised through the political action of the workers as a class.[46] Thus, at this stage of the dialectical presentation, both this latter remark and the one discussed above regarding the totally-developed individual as the basis for the abolition of capital, cannot be but unmediated observations, external to the concrete determinations of the productive subjectivity of large-scale industry that we have before us. On the other hand, inasmuch as the latter *does* involve *a certain degree* of universality, a limited, albeit real, expression of the underlying tendency for the production of its fully-developed shape, Marx's reflections, although external, are undoubtedly pertinent. From a methodological point of view, he could therefore legitimately introduce those remarks in order to anticipate the direction that the further unfolding of this historically-specific contradiction of the capitalist mode of production – 'the only historical way in which it can be dissolved and then reconstructed on a new basis' – should take.[47] But as a proper, complete dialectical account of the determinations underlying the proletarian conquest of political power or, above all, of the revolutionary production of the free association of individuals, the presentation as so far developed definitely falls short.

This, in itself, should not be problematic. From the perspective of the dialectical investigation as such, this juncture of our critical reading of Marx's search for the determinations of revolutionary subjectivity is not a dead-end at all. It only means that our journey from the abstract to the concrete needs to proceed forward as our end-point – namely, revolutionary subjectivity – still lies ahead. In this sense, no anomaly lies before us. However, the question is very different when approached from the standpoint of the elements for such an investigation we can find already objectified in Marx's *Capital*. In that respect, the problem that the contemporary reader of *Capital* attempting to discover those determinations faces is, to put it briefly, that *they are not there*. Let us expand on this point.

---

[45] Marx 1976a, p. 619.

[46] This would need the exposition of the tendency for the concentration and centralisation of capital as the alienated expressions of the socialisation of labour in the capitalist mode of production and whose absolute limit is reached when the total capital of society immediately exists as a single capital. Compare Marx 1975, p. 780.

[47] Marx 1976a, p. 619.

We have seen how Marx, when faced with the tendential universality of the worker of large-scale industry and the growing conscious regulation of social labour it entails, *extrinsically* reflects upon the specific material form of productive subjectivity necessary to 'build society anew' on a really free basis. On the other hand, we have highlighted the methodological pertinence of such a reflection given that – as the passage on 'really free working' from the *Grundrisse* quoted above stated – the latter itself has as one of its determinations that of being a bearer of universal productive attributes, that is, capable of 'material production of a general character'. So far so good. But, as the reader will remember, the attribute of universality did not exhaust the determinations of the form of *productive* subjectivity with the immediate potentiality for 'really free working' (which, as I argued, should provide the material foundation of revolutionary *political* subjectivity). In the first place, the latter also entailed a process of material production whose general social character was immediately posited. This condition is present – at least tendentially – in the productive subjectivity of large-scale industry as developed in *Capital* too.[48] But, in addition, note that Marx's passage from the *Grundrisse* mentions that the universality of 'revolutionary' productive subjectivity must be the expression of a *scientific* consciousness, capable of organising work as 'an activity regulating all the forces of nature'. And here lies the crux of the matter.

Although the productive subjectivity of the worker of large-scale industry as presented in *Capital* tends to become universal, this universality is not the product of the *scientific expansion* of his or her capacity consciously to regulate the production-process, but of the increasing (eventually absolute) *deprivation* of all knowledge of the social and material determinations of the labour-process of which he or she is part. As we have seen above, for the workers engaged in the direct process of production, the separation of intellectual and manual labour reaches its plenitude. This kind of labourer can certainly work in any automated labour-process which capital puts before him or her, but not as the 'dominant subject' with 'the mechanical automaton as the object'. Rather, for those workers 'the automaton itself is the subject, and the workers are merely conscious organs, co-ordinated with the unconscious organs of the automaton, and together with the latter, subordinated to the central moving force'.[49] The scientific productive powers needed to regulate the forces of nature, and which are presupposed by their objectified existence in a system of machinery, are not an attribute that capital puts into the hands (or, rather, the heads) of direct labourers. In brief, in the figure of this wage-labourer bearing what, following Iñigo Carrera,[50] I term an absolutely *degraded productive subjectivity*, scientific consciousness and universality do not go together but are in opposition to one another. In other words, it is not this degraded productive subjectivity that, simply as such, carries in its immediacy the historical revolutionary powers that Marx himself considered necessary to make capital 'blow sky high'. Moreover, neither has Marx's exposition demonstrated that the very movement of the present-day alienated general social relation – capital-accumulation – leads to the social necessity to transform, in the political form of a revolution, the productive subjectivity of those labourers in the direction of their re-appropriation of the powers of scientific knowledge developed in this alienated form.

---

[48] In the chapter on 'Machinery and large-scale industry', the tendency to expand the scope of the conscious regulation of the social character of labour co-exists with an opposite tendency to multiply the number of privately-mediated branches of the social division of labour, which is also the product of the movement of this form of production of relative surplus-value. See Marx 1976a, p. 572. But no reason is given for one or the other tendency to prevail. This occurs later in Marx's presentation, when he unfolds the determinations of the 'General law of capitalist accumulation'. There, the tendencies to the concentration and centralisation of capital show how the first tendency eventually imposes itself over the second.

Yet, despite this insufficiency as an account of the material genesis of the revolutionary subject, it is here that Marx's exposition in *Capital* of the determinations of human productive subjectivity as an alienated attribute of the product of labour comes to a halt.[51] In the rest of Volume I (and the two remaining volumes), Marx no longer advances, in any systematic manner, in the unfolding of the material and social determinations of the revolutionary subject. From the point of the presentation reached, and after moving to the exteriority of the inner determinations of the production of surplus-value and to its reproduction, accumulation and the general law that presides over its movement, he just makes a gigantic leap into the conclusion contained in the chapter on the 'Historical tendency of capitalist accumulation', offering the following well-known account of the determinations leading to the abolition of the capitalist mode of production:

> Along with the constant decrease in the number of capitalist magnates, who usurp and monopolize all the advantages of this process of transformation, the mass of misery, oppression, slavery, degradation and exploitation grows; but with this there also grows the revolt of the working class, a class constantly increasing in numbers, and trained, united and organized by the very

---

[49] Marx 1976a, pp. 544–5.

[50] Iñigo Carrera 2003.

[51] This statement needs qualification insofar as the creation of a surplus population relative to the needs of the accumulation process also constitutes a transformation of productive subjectivity produced by the development of large-scale industry. More concretely, it represents the most extreme case of material mutilation of the productive attributes of the working class, that is, not simply their degradation but their outright non-reproduction.

> mechanism of the capitalist process of production. The monopoly of capital becomes a fetter upon the mode of production which has flourished alongside and under it. The centralization of the means of production and the socialization of labour reach a point at which they become incompatible with their capitalist integument. The integument is burst asunder. The knell of capitalist private property sounds. The expropriators are expropriated.[52]

If we leave aside the question of the misleading conflation between two *qualitatively different* (and, therefore, *analytically separable*) 'moments' of the revolutionary action of the working class contained in this passage – namely, the expropriation of the bourgeoisie and the abolition of capital – the question remains as to whether the determinations developed by Marx in the previous chapters suffice to justify the transition to this excessively simplistic and all too general account of the way 'the capitalist integument is burst asunder'.[53] Certainly, the tendency to the centralisation of capital discussed in the chapter on the 'General law of capital accumulation' does provide an exposition of the necessity behind the progressive socialisation of labour as an attribute of the capitalist form of private labour. But such an account stops short at the exteriority of the *quantitative determination* of the scope of consciously organised social labour without saying anything about the *qualitative transformations* of the productive subjectivity of the collective labourer that such an extension of the scale of the former presupposes. Seen from that perspective, I think that the transition to revolutionary subjectivity contained in the passage is definitely unmediated.

---

[52] Marx 1976a, p. 929.

[53] Whatever the ambiguities of Marx's formulation in the passage from the chapter on the historical tendency of capital-accumulation cited above, a cursory reading of his so-called 'political writings' makes evident that he was very clear about the 'unity-in-difference' between the expropriation of the bourgeoisie and the abolition of capital. To begin with, this is synthesised in the political programme of the working class to be implemented through the revolutionary 'conquest of political supremacy' contained in the *Communist Manifesto*, whose *immediate* economic content unequivocally comes down to the absolute centralisation of capital in the form of state-property (hence the abolition of the bourgeoisie) and the universalisation of the conditions of reproduction of the working class, but does not involve the abolition of the capitalist mode of production. See Marx and Engels 1976, pp. 92–3. As Chattopadhyay 1992, pp. 92–3, competently shows, for Marx the revolutionary conquest of political power together with the expropriation of the bourgeoisie were the *necessary forms* in which to *start* the process of transformation of the capitalist mode of production into the free association of individuals. But, unlike the conception found in Lenin and orthodox Marxism generally, Marx was very clear that the political rule of the working class 'does not by itself signify the collective *appropriation by society*, and does not indicate the end of *capital*' (Marx 1992c, p. 93). The 'dictatorship of the proletariat' was for Marx a *period within the capitalist mode of production* – hence, not a *non-capitalist transitional society* – in which capital was to be entirely revolutionised in every nook and cranny up to the point of fully preparing wage-workers for their self-emancipation – hence for their self-abolition as working class (Ibid.).

How are those workers whose productive subjectivity has been emptied of almost all content to organise the allocation of the total labour-power of society in the form of a *self-conscious* collective potency (the latter being what the abolition of capital is all about)? The growing 'misery, degradation, oppression and so on' certainly confront those labourers with particularly extreme *immediate* manifestations of the alienated mode of existence of their social being. Therefore, they could lead them to reinforce their collective resistance to capitalist exploitation by strengthening their relations of solidarity in the struggle over the value of labour-power. In themselves, however, those expressions of capitalist alienation have no way of transforming the class-struggle from a form of the reproduction of that alienation into the form of its fully self-conscious transcendence. From a materialist perspective, the question does not boil down to the will radically to transform the world, but to the objective existence of the material powers to do so. As Marx puts it in the *Holy Family*, it is about an 'absolutely imperative *need*' determined as 'the practical expression of *necessity*'.[54] The emergence of the social necessity underlying the historical constitution of the latter still involves the mediation of more revolutions in the materiality of the productive subjectivity of workers.

In this sense, I concur in general with those who claim that Marx's *Capital* is *incomplete*. However, this is not in the sense that the dialectic of capital needs to be complemented with that of class-struggle,[55] or with the political economy of wage-labour,[56] as if those latter aspects were not an inner moment of the former itself. Rather, I think that it is the very 'dialectic of capital' and, more concretely, the contradictory movement of the production of relative surplus-value through the system of machinery, that is in need of completion. Without this further exploration into the development of human productive subjectivity as an alienated attribute of social capital, a gap is bound to remain between the 'dialectic of human labour' unfolded in the relevant chapters of *Capital* and the revolutionary conclusions at the end of Volume I.

In the following section, I shall examine Marx's presentation of the determinations of the system of machinery in the *Grundrisse*. Although the complete *systematic* unfolding of the missing determinations is not there either, the main *elements* for such a further investigation of revolutionary subjectivity can be extracted from that text.

---

The *Grundrisse* and the system of machinery: in search of the missing link in the determinations of revolutionary subjectivity

As an entry-point to Marx's account of the system of machinery in the *Grundrisse*, let us return for a moment to our examination of the determinations of large-scale industry as presented in *Capital*. More concretely, let us go back to the relation between science and the production-process. Although this form of production of relative surplus-value entailed the general application of science as a productive force, the latter was not an attribute materially borne by those labourers engaged in direct labour in the immediate process of production. For them, that scientific knowledge took the form of an alien power already objectified in the machine. Marx notes this in the *Grundrisse* as well.[57]

Yet, as Marx puts it in the 'Results of the immediate production process', those scientific powers ultimately are themselves the products of labour.[58] Thus, although the *formal* subject of those powers – as happens with all the powers springing from the direct organisation of human co-operation – remains capital, the question immediately arises as to who is the *material* subject whose (alienated) *intellectual* labour develops the scientific capacities of the human species and organises their practical application in the immediate process of production. Having discarded manual labourers as such a productive subject, it would seem that the only alternative must be to turn our attention to the only remaining character present in the direct production-process, namely, the capitalist. Is it he or she who personifies, through the development of his/her productive consciousness and will, capital's need for the powers scientifically to control the movement of natural forces? The answer is given by Marx in a footnote to the chapter on 'Machinery and Large-Scale Industry' in *Capital*:

> Science, generally speaking, costs the capitalist nothing, a fact that by no means prevents him from exploiting it. 'Alien' science is incorporated by capital just as 'alien' labour is. But 'capitalist' appropriation and 'personal' appropriation, whether of science or of material wealth, are totally different things. Dr. Ure himself deplores the gross ignorance of mechanical science which exists among his beloved machinery-exploiting manufacturers, and Liebig can tell us about the astounding ignorance of chemistry displayed by English chemical manufacturers.[59]

Thus, it is not the capitalist who embodies the intellectual powers to develop the scientific knowledge presupposed by its objectified existence in a system of machinery. The science incorporated in the immediate production-process is the result of the appropriation of the product of the intellectual labour of an 'other'. This 'other', whose productive activity the direct production-process of large-scale industry carries as a necessary mediation, is not explicitly present in Marx's exposition in *Capital*. There might be two reasons for this exclusion. First, because in Marx's time such a social subject was only beginning to develop. Second, and following from the previous point, because Marx's presentation in *Capital* is restricted to the transformations suffered by the productive subjectivity of those workers remaining in the direct production-process. However, what his whole discussion implicitly suggests is that among the transformations that large-scale industry brings about is the extension of material unity comprising its total labour-process outside the boundaries of the 'factory walls'.[60] Hence, the direct process of production becomes just an aspect of a broader labour-process which now entails two additional moments: the development of the power consciously to regulate in an objective and universal fashion the movement of natural forces – namely, science – and the application of that capacity in the practical organisation of the automatic system of machinery and whatever remains of direct labour – the technological application of science, including the consciousness of the unity of productive co-operation. Certainly, these other moments are also present in *Capital*.[61] However, Marx's presentation there seems to revolve around the emphasis on their separated mode of existence *vis-à-vis* the subjectivity of direct labourers and which is presupposed by their activity. By contrast, in the *Grundrisse* he oscillates between such an angle on the question[62] and one which puts at the forefront the underlying material unity of the total activity of living labour, where the development of science and its technological applications act as essential constitutive moments.[63] With the system of machinery:

---

[57] Marx 1993, p. 693.
[58] Marx 1976b, p. 1055.
[59] Marx 1976a, p. 508.

> the entire production process appears as not subsumed under the direct skillfulness of the worker, but rather as the technological application of science. [It is,] hence, the tendency of capital to give production a scientific character; direct labour [is] reduced to a mere moment of this process.[64]

---

[60] In this analysis of the further determinations of the production-process of large-scale industry, I follow the approach developed in Iñigo Carrera 2003, pp. 1–37.

[61] Marx 1976a, p. 549.

[62] Marx 1993, pp. 692–4.

[63] Dunayevskaya 1989, pp. 80–6, correctly notes the difference in presentation between the account of the system of machinery in the *Grundrisse* – where the emancipatory potentialities of the system of machinery are considered – and the one in *Capital* – where its determination as a materialised expression of the domination of dead over living labour is emphasised. However, she wrongly attributes that to a change in Marx's view on the subject instead of as an account of *qualitatively different* potentialities engendered by the very same development of the system of machinery and personified by the different partial organs of the collective labourer.

[64] Marx 1993, p. 699.

The determinations presupposed by the production of relative surplus-value involve the specification of commodity-owners into capitalist and wage-labourer. Having discarded the former as the material subject of scientific labour, it is self-evident that only those determined as doubly free individuals can personify the development of this moment of the production-process of large-scale industry. Thus, although not explicitly addressed by Marx, the benefit of historical hindsight makes it very easy for us to recognise how the total social capital deals with its constant need for the development of the productive powers of science, namely, by engendering a special partial organ of the collective labourer whose function is to advance in the conscious control of the movement of natural forces and its objectification in the form of ever more complex automatic systems of machinery. Whilst the system of machinery entails the progressive deskilling of those workers performing what remains of direct labour – to the point of emptying their labour of any content other than the mechanistic repetition of extremely simple tasks – it also entails the tendential *expansion* of the productive subjectivity of the members of the intellectual organ of the collective labourer. Capital requires from these workers ever more *complex* forms of labour.[65] As much as those discussed in *Capital*, these are also 'immediate effects of machine production on the worker'. Needless to say, inasmuch as this expanded productive subjectivity is nothing more than a concrete form of the production of relative surplus-value, the exercise of the newly developed intellectual productive powers is inverted into a mode of existence of capital in its movement of self-valorisation as well.[66]

In this alienated form, capital thereby produces a material transformation whose fundamental significance exceeds the production of wage-labourers simply bearing different productive attributes. What is at stake here is, first and foremost, a radical substantial transformation of the very nature of human labour.[67] The latter progressively ceases to consist in the direct application of labour-power onto the object of labour with the purpose of changing its form. It now increasingly becomes an activity aimed at the conscious control of the movement of natural forces in order to make *them* automatically act upon the object of labour and, in this way, to effect its change of form. According to Marx's exposition of the system of machinery in the *Grundrisse*, *it is in the contradictory historical unfolding of this specific material transformation of human productive subjectivity that the key to the absolute limit to capital resides*.

---

[65] The so-called 'deskilling thesis', formulated in the seminal work by Braverman (Braverman 1998) is obviously a one-sided reduction of this *two-fold* movement of degradation/expansion of the productive subjectivity of the collective labourer required by the system of machinery to one of its moments. See Iñigo Carrera 2003, p. 32. One of the immediate reasons behind such a unilateral account lies, as Tony Smith points out, in its very restricted definition of 'skill', very much referring to *manufacturing* skills. See Smith 2000, p. 39.

[66] That is, the productive powers of science take an alienated form not just *vis-à-vis* manual labourers, who face them already objectified in the system of machinery. Intellectual labourers also confront the development of science they themselves personify as an alien power borne by the product of their social labour. Moreover, the alienated nature of this development of intellectual labour is even expressed in its general scientific form, that is, in its method. In its determination as a form of the reproduction of capital, scientific knowledge is bound to represent natural and social forms as self-subsistent entities or immediate affirmations, and their relations as inevitably external ones. For an elaboration of this point, see the chapter in this book by Iñigo Carrera. See also Iñigo Carrera 1992 and Starosta 2003.

> To the degree that labour-time – the mere quantity of labour – is posited by capital as the sole determinant element, to that degree does direct labour and its quantity disappear as the determinant principle of production – of the creation of use-values – and is reduced both quantitatively, to a smaller proportion, and qualitatively, as an, of course, indispensable but subordinate moment, compared to general scientific labour, technological application of natural sciences, on one side, and to the general productive force arising from social combination [*Gliederung*] in total production on the other side – a combination which appears as a natural fruit of social labour (although it is a historic product). *Capital thus works towards its own dissolution as the form dominating production.*[68]

To put it briefly, the issue here is the old question of the relation between intellectual and manual labour. More concretely, the fundamental point to grasp is the specifically capitalist form in which the antithetical movement of those two moments of living labour asserts itself with the development of the system of machinery. The revolutionary aspect of this historically-specific transformation of living labour in capitalist society is that both the scale and complexity of the production-process and, in particular, the increasingly scientific character of its organisation, make the subjectivity of the capitalist (the non-labourer) impotent to personify the now directly social labour under the rule of his or her capital. This means, in other words, that the development of the powers of intellectual labour and their exercise becomes an attribute of the 'labouring classes'.[69]

---

[67] Iñigo Carrera 2003, p. 11.

[68] Marx 1993, p. 700, my emphasis.

[69] On the superfluity of the capitalist, see especially Marx's concise comments in *Theories of Surplus Value* (Marx 1989a, p. 499). The complexity and scale of the co-operation of the collective worker of large-scale industry render the subjective powers of the capitalist impotent to personify in the name of his or her capital even the unproductive labour of superintendence of the productive organs of the former. All the functions of supervision, coercion and management come to be personified by a partial organ of the collective labourer. See Marx 1976a, p. 549; and Marx 1991b, pp. 510–1. The parasitic nature of the capitalist, though not yet of capital, thereby becomes increasingly concrete. And note that this expresses an alienated necessity of the accumulation of social capital itself:

The scientifically-expanded productive subjectivity of intellectual labour is, by its own nature, increasingly general or universal. The exertion of this form of human labour-power aims at the expansion of the conscious control over the *totality* of the forces of nature. Moreover, this subordination of the latter to the powers of living labour involves the comprehension of their *general* determination in order thereby to develop their *particular* technological applications in ever-evolving systems of machinery. Thus, as Marx puts it in *Capital* Volume III of in order to highlight its specificity *vis-à-vis* co-operative labour, scientific labour is, by definition, universal labour.[70]

With the constitution and permanent revolutionising of this organ of the collective labourer, capital thereby engenders *another* tendency for the production of workers bearing a universal productive subjectivity. However, this universality is no longer the *empty* universality deriving from the absolute *lack* of individual productive capacities to which direct labourers are condemned. When developed into its plenitude, it becomes the rich, concrete universality of organs of a collective subject who become increasingly able consciously to rule their life-process by virtue of their capacity to scientifically organise the production-process of any automatic system of machinery and, therefore, any form of social co-operation on the basis of large-scale industry. As the productive subjectivity of workers expands, it progressively ceases to be the case that the worker's individuality vanishes 'as an infinitesimal quantity in the face of the science, the gigantic natural forces, and the mass of social labour embodied in the system of machinery'.[71] For the latter *are* the direct products of the objectification of their productive subjectivity:

> Nature builds no machines, no locomotives, railways, electric telegraphs, self-acting mules etc. These are products of human industry; natural material transformed into organs of the human will over nature, or of human participation in nature. They are *organs of the human brain, created by the human hand*; the power of knowledge, objectified. The development of fixed capital indicates to what degree general social knowledge has become a *direct force of production*, and to what degree, hence, the conditions of the process of social life itself have come under the control of the general intellect and been transformed in accordance with it. To what degree the powers of social production have been

---

the consumption of the capitalist represents a deduction of the potential surplus-value that could be devoted to its self-expansion. Incidentally, the confusion over the parasitic nature of the capitalist and that of the capital-form as such underlies Negri's views of the present, 'Post-Fordist' forms of human co-operation as carrying in their immediacy – that is, without the mediation of more material transformations – the potentiality to explode the capital-relation. See Negri 1992, pp. 65–8, and Negri 1999, pp. 156–60.

[70] Marx 1991b, p. 199.

[71] Marx 1976a, p. 549.

> produced, not only in the form of knowledge, but also as immediate organs of social practice, of the real life process.[72]

We saw how in *Capital* Marx focused on the 'negative side' of the effects of production of relative surplus-value through the system of machinery upon the material forms of the productive subjectivity of the working class. The historical emergence of the social necessity for the constitution of a 'fully-developed social individual' thus appeared as an abstract possibility, whose connection to capital's development of machine-based production seemed to be completely external. Conversely, we can appreciate now how in the *Grundrisse* Marx posits capital's relentless tendency to 'call to life all the powers of science and of nature, as of social combination and of social intercourse'[73] as necessarily engendering the historical becoming of that concrete universal subjectivity itself.

> No longer does the worker insert a modified natural thing [*Naturgegenstand*] as a middle link between the object [*Objekt*] and himself; rather, he inserts the process of nature, transformed into an industrial process, as a means between himself and inorganic nature, mastering it. He steps to the side of the production-process instead of being its chief actor. In this transformation, it is neither the direct human labour he himself performs, nor the time during which he works, but rather the appropriation of his own general productive power, his understanding of nature and his mastery over it by virtue of his presence as a social body – it is, in a word, the development of the social individual which appears as the great foundation-stone of production and of wealth.[74]

Moreover, and here in accordance with *Capital*, he presents the latter as the one whose further expansion eventually clashes with its alienated capitalist social form and, therefore, as the material form of productive subjectivity that carries as an immediate potentiality the necessity for the 'creation of the new society'. Hence, Marx continues:

> The *surplus labour of the mass* has ceased to be the condition for the development of general wealth, just as the *non-labour of the few,* for the development of the general powers of the human head. With that, production based on exchange value breaks down, and the direct, material production process is stripped of the form of penury and antithesis.[75]

[72] Marx 1993, p. 706.
[73] Marx 1993, p. 706.
[74] Marx 1993, p. 705.
[75] Marx 1993, pp. 705–6.

It might seem that Marx is here substituting the intellectual labourer for the manual labourer as the revolutionary subject. However, the point is that the key does not consist in abstractly opposing intellectual and direct manual labour in order to privilege one over the other, but in grasping the contradictory forms in which capital historically develops these two necessary moments of the labour-process. Since Marx's exposition in the *Grundrisse* is only concerned with the *general* tendency and, more specifically, its historical result – that is, with the movement of 'bourgeois society in the long view and as a whole'[76] – he does not pay much attention to the contradictory forms in which the latter asserts itself. However, it is clear that in the historical unfolding of the tendency for the progressive objectification of all direct application of human labour-power onto the object of labour as an attribute of the machine, capital actually *reproduces and exacerbates* the separation between intellectual and manual labour.[77]

In effect, inasmuch as capital's conversion of the subjective expertise of the direct labourer (both intellectual and manual) into an objective power of the machine is not an instantaneous event but only done by degrees, every leap forward in the abolition of manual labour brought about by the revolution in the material forms of the process of production is realised by actually multiplying the spaces for the exploitation of manual living labour. In fact, the new technological forms themselves might generate as their own condition of existence the proliferation of a multitude of production-processes still subject to the manual intervention of the labourer, whether as an appendage of the machine, as a partial organ in a manufacturing division of labour or even in the form of 'domestic industry'. Thus, until the conditions for the (nearly) total elimination of manual labour are produced, direct labour as an appendage of the machine and/or the division of labour of manufacture tend to be reproduced under the new conditions and with even more degraded forms of productive subjectivity and harsher conditions of capitalist exploitation.[78]

---

[76] Marx 1993, p. 712.

[77] One of the central weaknesses of recent theories of 'immaterial labour' or 'cognitive capitalism', which heavily rely on the 'Fragment on machines', is their 'stageist' reading of that text. See, for example, Virno 2007; Lazzarato 1996; Vercellone 2007. In other words, those authors use those passages from the *Grundrisse* for a formalistic specification of a qualitatively different stage of capitalist development that is said to supersede not only large-scale industry but the real subsumption as well: the epoch of the 'general intellect'. Worse still, those theories unmediatedly – hence speculatively – apply the essential tendency and finished form described in the *Grundrisse* onto contemporary concrete forms of realisation that still represent its negation. The result is that they overlook or downplay the contradictory movement of expansion/degradation and universalisation/particularisation entailed by current material forms of the real subsumption. As we have seen, what the 'Fragment on machines' unfolds is not the abstract opposite of the determinations of the productive subjectivity of large-scale industry but their more concrete development. The significance of that undoubtedly essential text is therefore *systematic*. And, incidentally, so is that of the distinction between the three different forms of the real subsumption presented in *Capital* and that between formal and real subsumption. For a forceful case against the 'stageist' reading of those chapters of *Capital*, see Tomba 2007.

Yet, it is certainly the case that this internal differentiation of the collective labourer on the basis of the respective forms of productive subjectivity is the self-negating form in which the *abolition* of that separation is realised in the historical process. Thus, through the very exacerbation of their separation, capital tendentially abolishes the qualitative and quantitative weight of manual labour in the process of the reproduction of social life, thereby converting the essential moment of living labour into an intellectual process. In this way, capital's transformation of the labour-process eventually reaches a point in which the separation between intellectual labour and what is now a quantitatively and qualitatively insignificant amount of manual labour, cannot materially obtain as a form of organising the life-process of humanity. The development of the material productive forces of society can only assert itself through the embodiment of the intellectual powers of social production in the individual subjectivity of every partial organ of the now directly social productive body. Moreover, this incorporation of the powers of the 'general intellect' into every individual worker must now have the form of objective social knowledge – namely, science – instead of being the product of the immediate subjective productive experience of the labourer (as was the case of independent handicraft-production). As we shall see below, it is the consciously organised political action of the *whole* working class – whatever its productive subjectivity – that is the necessary form in which this latter material transformation is realised.[79]

---

[78] This is illustrated by Marx in section eight of the chapter on 'Machinery and large-scale industry' in *Capital*. There he shows how the production of relative surplus-value through the system of machinery reproduces modern manufacture, handicrafts and domestic industry. In this way, capital not only revolutionises the determinations of the social existence of those workers incorporated into large-scale industry but also of those of the sections of the working class still working under the division of labour in manufacture or domestic industry. The latter forms of the social production-process persist in their survival only through the imposition of the most brutal forms of the exploitation of the workers. However, Marx makes clear that the subsistence of manufacture and domestic industry is always provisional, even if it appears to hang on for long periods of time. The general tendency of capital is for the total development of large-scale industry. Moreover, Marx's discussion makes clear that the working class does not have to 'sit and wait' until the limit for the subsistence of manufacture is reached – a limit given by the extent to which the over-exploitation of labour-power compensates for its relative lower productivity of labour *vis-à-vis* large-scale industry. Inasmuch as the struggle for the shortening of the working day succeeds in forcing its implementation in the branches of production where manufacture persists, it accelerates the development of large-scale industry by not allowing the selling of labour-power below its value and, therefore, by reducing the capitalist limit to the introduction of machinery. Here we have a clear instance of the way in which progressive politics mediates revolutionary politics, the former being the concrete form of the development of the material determinations for the emergence of the latter.

In its formally boundless movement of self-valorisation, capital therefore cannot stop in the historical production of universal productive subjects. At the same time, this constant revolution in the material forms of human productive subjectivity can only take place through the progressive socialisation of private labour, thereby positing the extension of the scope of the conscious regulation of directly social labour as an immediate necessity for capital's production of relative surplus-value. Thus, through the development of large-scale industry, capital works towards the historical emergence of the other precondition for 'really free working' as well:

> In the production process of large-scale industry … just as the conquest of the forces of nature by the social intellect is the precondition of the productive power of the means of labour as developed into the automatic process, on one side, so, on the other, is the labour of the individual in its direct presence posited as suspended individual, i.e., as social, labour. Thus the other basis of this *mode of production falls away*.[80]

On the two-fold basis of the expansion of the scientific productive powers of the 'social intellect' and of the determination of human labour as directly social, capital moves right towards reaching its absolute historical limit as a social form. This limit is not reached when capital-accumulation *ceases* to develop the material productive forces of society as, following Trotsky, orthodox Marxists would have it.[81] On the contrary, capital clashes with its limit when the very same alienated socialisation and scientific universalisation of the powers of human labour through the production of relative surplus-value begets, *as its own immanent necessity*, the development of the productive forces of society in a particular material form, namely: the fully conscious organisation of social labour as the *general* social relation regulating the reproduction of human life and, therefore, as an attribute borne by every singular productive subjectivity comprising the collective labourer. Under those circumstances, the further leap forward in the material productive forces of society – dictated by the most immediate necessity of capital itself, that is, the production of relative surplus-value – comes into conflict with capitalist relations of production. Translated into our mode of expression, this classical Marxian insight can only mean the following: the *alienated* social necessity arises for the human being to be produced as a productive subject that is fully and objectively conscious of the social determinations of his/her individual powers and activity. Thus, he or she no longer sees society as an alien and hostile potency that dominates him/her. Instead, he or she consciously experiences the materiality of social life (that is, productive co-operation) as the necessary condition for the development of the plenitude of his or her individuality, and therefore consciously recognises the social necessity of the expenditure of his or her labour-power in organic association with the other producers. However, this form of human subjectivity necessarily collides with a social form (capital) that produces human beings as *private and independent individuals* who consequently see their general social interdependence and its historical development as an alien and hostile power borne by the product of social labour. The determination of the material forms of the labour-process as bearers of objectified social relations can no longer mediate the reproduction of human life. *Capital-accumulation must therefore come to an end and give way to the free association of individuals*:

---

[79] Besides, it goes without saying that, although the workers bearing an expanded productive subjectivity express the *movement towards* the development of a universal individuality, they do so within the limits of capital as an alienated social form. In other words, it is not the *immediate actuality* of the material forms of their productive subjectivity that constitutes the kind of 'rich and all-sided individuality' discussed by Marx (1993, p. 325), As much as they are workers with a degraded productive subjectivity, they not only have to change 'society' but also undergo a process of self-change in the course of the revolutionary process. Hence, *both* organs of the collective labourer have to 'get rid of the muck of ages' imposed by the determination of human subjectivity as a concrete form of the reproduction of relative surplus-value. More concretely, this entails the *transformation* of intellectual labour (that is, of the mode of scientific cognition or the kind of scientific method) and its *generalisation*. See note 66 above.

[80] Marx 1993, p. 709.

[81] Trotsky 2002, pp. 1–2.

> But with the suspension of the *immediate* character of living labour, as merely *individual*, or as general merely internally or merely externally, with the positing of the activity of individuals as immediately general or *social* activity, the objective moments of production are stripped of this form of alienation; they are thereby posited as property, as the organic social body within which the individuals reproduce themselves as individuals, but as social individuals. The conditions which allow them to exist in this way in the reproduction of their life, in their productive life's process, have been posited only by the historic economic process itself; both the objective and the subjective conditions, which are only the two distinct forms of the same conditions.[82]

Thus, it is the historically-determined necessity for the fully-developed and socialised universality of the productive subjectivity of the workers, beyond its capitalist 'integument' but *generated as an immanent determination of the alienated movement of capital itself*, that is realised in the concrete form of the communist revolution. This suggests that *the revolutionary political consciousness of the*

---

[82] Marx 1993, p. 832.

working class can only be a concrete expression of their productive consciousness.[83] What the political action of the self-abolishing proletariat realises (its content) is, fundamentally, the transformation of the materiality of the productive forces of the human individual and, *therefore*, of their social forms of organisation and development. To put it differently, it is about a *material* mutation of the production-process of human life, which takes concrete shape through a transformation of its *social* forms which, in turn, expresses itself through a conscious *political* action, namely, a revolution. Thus, the issue here is not one of finding the external 'objective *conditions*' that trigger or facilitate the development of a self-determining political action, but of unfolding the inner or immanent material and social determinations of capital-transcending conscious practice. In other words, at stake here is the *content and form* of the necessity to abolish the capital-form.

To recapitulate, we can now appreciate the significance of the 'Fragment on machines' from the *Grundrisse*. Although clearly in an unsystematic fashion (after all, they are only research-manuscripts), that earlier version of the critique of political economy contains the elements for the systematic unfolding of the plenitude of the determinations that constitute the immanent *content* of capital-transcending transformative practice that *Capital* only partially achieves. However, it is actually the latter text that unfolds the necessity of its *form*, namely, the conscious political action of the whole working class. As we have seen, through the discussion of the factory-acts, Marx unfolds the determination of the political action of the working class as the necessary mediation, in the form of a consciously organised collective action, for the imposition of the *general* conscious regulation of social labour in the capitalist mode of production; that is, as a concrete form of the essentially *unconscious* – hence inverted – organisation of social life through the capital-form. But furthermore, we saw above that the struggle of wage-labourers as a class was also the necessary form in which social capital's need for workers with an increasingly universal productive subjectivity, resulting from the movement of the *real* subsumption in the form of large-scale industry, asserted itself. True, in Marx's exposition in Chapter fifteen of *Capital* the class-struggle does not transcend its determination as a mediating moment of social capital's reproduction. This is because he does not unfold its immanent material content – the socialisation and universal development of human productive subjectivity – up to its absolute limit. But this is precisely what the *Grundrisse* do; that is, they do not unfold a *different* content but develop a more complex shape of that content itself. *A fortiori*, its concrete mode of realisation remains the same: the struggle of wage-labourers as a class. A struggle, however, that is no longer determined as form of capital's reproduction. As an expression of the plenitude of its content, the political action of wage-labourers now becomes determined as the mode of existence of capital-transcending human practice. Hence the general determination of the communist revolution: to be the political form taken by the historical production of the subjectivity of the 'rich individuality which is as all-sided in its production as in its consumption, and whose labour also therefore appears no longer as labour, but as the full development of activity itself'.[84]

---

[83] It also suggests that revolutionary action is an expression of an alienated subjectivity. In other words, the abolition of capital is not the product of an abstractly free, self-determining political action, but one that the workers are *compelled* to do as personifications of the alienated laws of movement of capital itself. See Iñigo Carrera 2003. What sets capital-transcending political action apart from capital-reproducing forms of the class-struggle is its specific determination as a collective action that is fully conscious of its own alienated nature, of personifying a necessity of social capital. However, by becoming conscious of their determination as a mode of existence of capital, revolutionary workers also discover the historic task that as fully conscious yet alienated individuals they have to undertake: the supersession of capital through the production of the communist organisation of social life. Revolutionary subjectivity therefore organises an alienated political action that in the course of its own development liberates itself from all trace of its alienated existence.

Conclusions

This chapter has argued that, in their unity, the *Grundrisse* and *Capital* provide the elements for the scientific exposition of the determinations of capital leading to the social constitution of the revolutionary working class. This exposition must actually comprise the reproduction in thought of the concrete unity of *all* the determinations of social existence implied in the necessity for the abolition of capital, starting with its simplest form, namely, the commodity. However, for obvious reasons of space, the discussion centred on the specific form of capital that carries the necessity of its own supersession as an immediate potentiality. That form, this paper has argued, lies in the fully developed shape taken by the real subsumption of labour to capital: the system of machinery.

As we have seen, Marx's treatment of large-scale industry in *Capital* differs from the exposition he had initially formulated in his research-manuscripts known as the *Grundrisse*. This has led many scholars to see the two perspectives as somehow incompatible, maybe even reflecting a change of mind on the part of Marx, from an early optimistic view of the emancipatory potentialities of the forms of the real subsumption to a more pessimistic view of the latter as yet another expression of the despotic rule of dead over living labour. This paper has offered a different reading of this aspect of Marx's intellectual development. Whilst it is certainly true that Marx's exposition changed from the *Grundrisse* to

---

[84] Marx 1993, p. 325.

Capital, this difference does not express two inconsistent views of the determinations of the productive subjectivity of large-scale industry. Rather, each text actually centres the exposition on the development of *one* of the *two essential contradictions* that characterise the most complex form of the real subsumption and whose development constitutes the immanent ground of revolutionary subjectivity. In *Capital*, the exposition focuses on the 'absolute contradiction'[85] between *particularity and universality* of the development of productive subjectivity, leading Marx to emphasise the material *degradation* of individuality of the wage-labourer of large-scale industry. By contrast, in the *Grundrisse* Marx focuses his attention on the development of the contradiction between the *intellectual and the manual* moments of the production-process under the rule of capital, leading him to unfold the tendency for the scientific *expansion* of the subjectivity of the doubly free labourer. Both contradictions are, however, two sides of the same coin: the alienated form in which human beings produce the materiality of their species-being at a certain stage of development and on the basis of specific historical presuppositions.[86]

> But it is an insipid notion to conceive of this merely *objective bond* as a spontaneous, natural attribute inherent in individuals and inseparable from their nature (in antithesis to their conscious knowing and willing). This bond is their product. It is a historic product. It belongs to a specific phase of their development. The alien and independent character in which it presently exists *vis-à-vis* individuals proves only that the latter are still engaged in the creation of the conditions of their social life, and that they have not yet begun, on the basis of these conditions, to live it.[87]

As we have seen, this development does not only involve the *formal* inversion between subject and product of social labour but also the *material* mutilation of the productive individuality of wage-labourers. However, Marx was also clear about the *relative historical necessity* of those forms, if only as a *vanishing moment* in the world-historical process of development of the materiality of 'really free working' and, hence, in the production of the necessity of their own supersession.[88]

---

[85] Marx 1976a, p. 617.

[86] Those historic presuppositions entail a degree of development of the productive individuality of the human being historically attaining 'adequate classical form' in the form of the *freedom and independence* of the *isolated* individual labour of the peasant and the artisan, that is, on the basis of the *dissolution* of all relations of personal dependence. See Marx 1976a, p. 927, and Marx 1993, p. 156. The material specificity of capital, which it formally achieves in an alienated form, consists, precisely, in the socialisation of free but isolated labour. Marx 1976a, p. 927.

Towards a "Unified Field Theory" of Uneven Development: Human Productive Subjectivity, Capital and the International

GREIG CHARNOCK and GUIDO STAROSTA

This article puts labour, and its historically changing forms of existence, at the centre of the theorisation of uneven international development. It advocates a consciously dialectical approach that goes beyond significant limitations in historical-geographical materialism, and in the work of Neil Smith in particular. It argues, first, that geopolitical modes of explanation cannot be asserted on descriptive grounds, or in logical abstraction from the determinate content of social reproduction. It then argues that the critique of uneven development must focus on the material process Marx termed the "real subsumption of labour to capital" so as to analyse the transformation of the productive subjectivity of the international working class in contemporary capitalism. This transformation has today resulted in the contemporary form of a "new" international division of labour, the worldwide dynamics of which are mediated by a variety of specific national and regional forms of the capital accumulation process.

In *Global Society*, Vol. 29, No. 4, Sébastien Rioux mounts an incisive critique of international relations literatures that take Leon Trotsky's idea of "uneven and combined development" (U&CD) as the main conceptual prism through which to provide a critical, historical materialist explanation of "the international" and of worldwide socio-historical change.[1] Rioux's principal criticism is that U&CD theory takes for granted that which needs to be theorised, namely the question of "why and how capitalist development is uneven and combined"—a problem inherited from Trotsky himself who, as Rioux explains, only asserts the general law-like validity of U&CD on immediate, descriptive grounds. This, he argues, ultimately leaves us bereft of "the necessary theoretical development of categories and concepts that can account for the historically specific dynamics of social change by tracing back its logical connections to the *inner structural dynamics of development itself*".[2] In lacking such a substantive theorisation of uneven international

development on the basis of these specific dynamics, Rioux's arraignment against the U&CD literature finds it culpable of conflating "the *fact* of U&CD as a *theory* of U&CD".[3]

Our aim in this article is not to intervene in any debate between Rioux and U&CD theorists. Rather, we seek to depart from Rioux's own, more reconstructive suggestion that the key to finding a "unified field theory" of uneven development might lie in a set of "historical-geographical materialist" literatures that are largely ignored in international relations scholarship.[4] We note that while making this suggestion Rioux is keen to transcend the antinomy, or dualism, between the Marxian analysis of the "organic tendencies" of capitalist development on the one hand, and a transhistorical conception of inter-societal interaction, on the other. In this article, we therefore outline our own proposal for the development of a theory of uneven international development that might transcend the dualism between these two sociological and inter-societal "logics". Indeed, what we propose is a theory that seeks to avoid any kind of dualism, exteriority or "gap" in the theorisation of uneven development—including any dualism between theory, on the one hand, and the historical development of concrete "empirical" forms, on the other.[5] In other words, we seek to vindicate a consciously *dialectical* approach to the question of uneven development and the international that reproduces neither the crude empiricism of approaches that depart from—but do not go beyond—the immediacy of concrete phenomena, nor the application of a speculatively arrived at "framework" of concepts and categories—or a "model"—upon concrete reality (giving rise to the violence of abstraction characteristic of structuralist Marxism, for example). Rather, our approach acknowledges the dialectical unity of the content and form of concrete social phenomena, and on the basis of the recognition of the general determination of the process of social reproduction specifically in, what Marx termed, "bourgeois society". Accordingly, we will argue, much as Rioux appears to suggest is already established by historical-geographical materialism—and in the work of the late Neil Smith, in particular—that the key to providing something like a "unified field theory" of uneven development is dialectically rooted in the intrinsic, material unity between human beings and nature, and the socially mediated character of that unity (hence between productive forces, social relations of production, and their actualisation in and through the conscious practice of individuals).[6] In other words, we want to put *labour*, and its historically changing forms of existence, at the centre of the theorisation and analysis of uneven international development.

We therefore begin by summarising what we think is the more productive contribution to the theorisation of uneven development to be found in Smith's pioneering work, namely his insistence that uneven development is a *determined* outcome of "the production of nature", i.e. of socio-ecological metabolism under specifically capitalistic social relations.[7] Yet our actual intent in this first section is to revisit this contribution in order to highlight what we think are deficiencies in historical-geographical materialism more generally, and which, ultimately, limit its ability to explain uneven development without also falling into a trap of relying on ungrounded, unexplained and indeterminate "laws" of capitalist development that derive from—and serve to reproduce—a dualism that is not so very different from that which Rioux seems to identify (in his own terms) as being so problematic in U&CD theory.

[7] We recognise that the term "determination", which we use throughout this article, will for some readers immediately smack of a vulgar economic functionalism in which a great many "superstructural" phenomena might be explained with recourse to a mechanistic, causal relation with the "economic

Our own contribution is therefore to build upon the "rational kernel" of Smith's production of nature thesis so as to advance a theory of world-historical social change and uneven development that is wholly grounded in the materiality of the "web of socio-ecological life", to borrow a term from Harvey,[8] but which can begin to explain contemporary dynamics of uneven development and inter- (and, indeed, intra-) societal relations without relying upon indeterminate, trans-historical "laws of unevenness". We argue in this first section that the key to arriving at a substantive, materialist theory of the international and of uneven development is to, first, recognise that one simply cannot assert the autonomy of "the political"—and therefore of geopolitical modes of explanation—on descriptive grounds or in "logical" abstraction from its determinate social content.[9] In short, we suggest, the international as composed of different national state forms is today part and parcel of capital's "second Nature", and therefore should be explained on the basis of its substantive content and what is really at stake in the general process and product of uneven international development (albeit in a highly mediated form), namely the transformation of human productive subjectivity (or, more simply, *labour*), and the changing forms of the global production of relative surplus-value as the historically specific, alienated form of that general process of transformation.[10]

---

base". For us, however, the term is central to dialectical inquiry and the recognition that reality is contradictory, the movement of contradiction. "Contradiction" here means that every real form (whether "natural" or "social") realises its own qualitative determination by transforming itself into a more concrete form, that the process of determination is a process of becoming another, i.e. a movement of self-negation. This form of movement, or the "inner life", of the concrete object that we want to inquire after by means of thought, needs to be observed through its specific modes of existence and development. Marx's *Capital* does precisely this: it is the ideal reproduction of the real determinations of capital as the alienated social subject of bourgeois society, starting with its simplest mode of existence—i.e. the commodity. See Juan Iñigo Carrera, *Conocer el Capital hoy: Usar críticamente El Capital* (Buenos Aires: Imago Mundi, 2007).

[8] David Harvey, "Notes Towards a Theory of Uneven Geographical Development", in *Spaces of Neoliberalization: Towards a Theory of Uneven Geographical Development* (Stuttgart: Franz Steiner Verlag, 2005), pp. 55–92.

[9] Though not picked up on by Rioux in his critique of the U&CD literature, it is noteworthy that the latter pays scant attention to debates among historical materialist scholars from the 1970s and 1980s in which heavy criticism was heaped upon the notion of the (relative) autonomy of the political. In our view, Simon Clarke and others working in the "open Marxist tradition" succeeded in articulating the most cogent, non-dualistic theorisation of the determination of the national state form. See Simon Clarke (ed.), *The State Debate* (Basingstoke: Palgrave Macmillan, 1991); Werner Bonefeld, "Global Capital, National State, and the International", *Critique: Journal of Socialist Theory*, Vol. 36, No. 1 (2008), pp. 63–72.

[10] The term "human productive subjectivity" denotes the power and capacity of the human individual to partake in the social metabolic process, that is, the conscious control over the social character of her individual labour. See Karl Marx, "Economic and Philosophical Manuscripts", in *Early Writings* (Harmondsworth: Penguin, 1975), pp. 279–400. In the capitalist mode of production, the productive attributes of individual workers include the strictly material or technical dimension of labour-power required by

The next dimension of our argument, then, is that in order to explain uneven development, and the outwardly manifest diversity of national "capitalisms", we must focus on the material process Marx termed the "real subsumption of labour to capital" and the transformation of the productive subjectivity of the international working class in contemporary capitalism. As we explain in section two of this article, this entails the recognition that the process of the production of relative surplus-value on a world scale leads to historically changing constellations of the international division of labour—much as Marx insisted was already a real tendency of the bourgeois mode of production and the system of large-scale industry as early as the 1840s.[11] More concretely, and as a contemporaneous manifestation of this more general foundation of the international, we argue in section three of the article that the global transformation of socio-ecological metabolism on the basis of the fragmentation of the productive subjectivity of the international working class has in recent years resulted in the contemporary form of a "new" international division of labour (NIDL). The inner, worldwide dynamics of this NIDL are mediated by a variety of specific national and regional forms of the capital accumulation process, such that each particular concrete national space of capital accumulation and societal reproduction bears its own empirically distinctive attributes in terms of institutional forms, labour markets, distributions of income and wealth, and, of course, competing ideologies and political cleavages.

On "the Production of Space, Scale and Nature under Capitalism" and the Limits to Smith's Theory of Uneven Development

In this first section, we pick up from where Rioux signs off in his *Global Society* article, and offer some initial grounds for a revitalised, unified theory of the international that is precisely grounded in the recognition that the reproduction of human life necessarily entails a metabolic relation with nature. For Rioux, the failure on the part of IR theorists to engage with Smith, as well as his fellow historical-geographical materialist David Harvey, is significant because they have already identified the necessity for a "unified field theory" that might explain worldwide socio-historical change. Smith and Harvey have also already gone some way towards explaining the uneven (and combined) development of a multiplicity of social and geopolitical forms on the basis of a materialist conception of the inner dynamics of capitalist development in historical time and space. Taking Rioux's cue, then, let us examine Smith's project to provide "a thorough spatial reconstruction of the concepts and categories pertaining to the capitalist mode of production" so as to begin to explain the international as we encounter it as being necessary and immanent to the reproduction of capital as the most general form of social

Jarvis (eds.), *Asia after the Developmental State: Disembedding Autonomy* (Cambridge: Cambridge University Press, 2017), pp. 125–129.

reproduction *today*.[12] As Rioux suggests, this necessitates a return to question of "the production of space, scale and Nature under capitalism".[13]

In our view, Smith's lasting contribution is to the theorisation of the dialectical unity of nature and society, and to how "the spatial scales of capitalism" are re-*produced*—with all of their geographical and geopolitical "unevenness"—as a "corollary" of the historically specific (i.e. capitalistic) form of mediated socio-ecological metabolism on a world scale.[14] This has significant ramifications for how we ought to resist any lapse into conceiving of certain spatial scales in immutable terms:

> the geographical scales of human activity are not neutral "givens", not fixed universals of social experience, nor are they an arbitrary methodological or conceptual choice … Rather, scale should be seen as materially real frames of social action. As such, geographical scales are historically mutable and are the products of social activity, broadly speaking.
>
> … At the very least, different kinds of society produce different kinds of geographical scale for containing and enabling particular forms of social interaction. The medieval city is the locus of feudal commerce and simultaneously a place to be defended from external military attack, while the modern metropolis is much more the expression of an expansive capitalism premised on large-scale production, widespread financial, service and communication networks, and mass consumption.[15]

This specificity, Smith argues, holds true as much for the production of the national state as for other spatial scales of social interaction:

> With the internationalisation of commercial capital in the seventeenth and eighteenth centuries, the question of coordinating competitive and cooperative relationships between capitals became increasingly vital. The nationalisation of capital, simultaneous with and as part of the internationalisation of capital, was the solution that emerged historically … National capitals and their attendant political frameworks in the nation-state emerged as a vital geographical means for coordinating and arbitrating economic competition between capitals at the global scale. National capitals are in effect different "laws of value" in a wider global market, and they remain coherent to the extent that the nation-states devised for the purpose succeed in protecting the gamut of social, economic and cultural conditions that sustain individual national capitals. That is, the functions of the state which were in

> earlier times attached to lower spatial scales of territorial control—city states, duchies, kingdoms, etc—are, *with the advent of capitalism, reconstituted at the scale of the nation*.[16]

On what basis does Smith make these claims? His conception of what he very much saw as a dialectical, non-dualistic theory of the production of space and scale, in general, was first expounded in his now classic book *Uneven Development*, in which he challenged a basic notion of space inherent to traditional Western epistemologies and indeed common parlance—that of "space as field, as a container, or as simple emptiness".[17] Influenced by the French Marxist Henri Lefebvre, he argued that space is itself a social product, and, moreover, has become an active moment in the production and reproduction of a historically specific (i.e. capitalist) worldwide socio-ecological landscape: "By its actions", he insists, "this society no longer accepts space as a container, but produces it; we do not live, act and work 'in' space so much as by living, acting, and working we produce space".[18] As a corrective to traditional theory, then, Smith sought to advance a systematic, Marxian understanding of how capital produces and re-produces variegated socio-geographical space "in its own image"[19]—a result he termed "uneven development" or "uneven geographical development".[20]

For Smith, an essential preliminary step in the appreciation of how capital produces space at various inter-relational scales is to first examine the *production of nature* under capitalism. This, he underlines, is a reflexively critical endeavour since it must penetrate the "delusive appearance of things",[21] and must question a core tenet of traditional Western thought in which "nature is generally seen as precisely that which cannot be produced; it is the antithesis of human productive activity".[22] On the basis of a critical reading of the Frankfurt School theorist Alfred Schmidt, in particular, Smith emphasises the central importance of the concept of socio-ecological metabolism (*Stoffwechsel*) in Marx's own critique of political economy, the key materialist-dialectical point being that "the whole of nature is socially mediated and, inversely, society is mediated through nature as a component of the total reality".[23] Or, to put it simply, in the historically evolving process of the social-ecological metabolism upon which human reproduction is based, seemingly prior and external nature itself increasingly becomes a *product*.[24] Smith here picks up on Schmidt's heuristic and "useful distinction between 'first nature' and a 'second nature'", which he subsequently refashions in *Uneven Development* so as to claim that "we must now consider there to be a social priority of nature; nature is nothing but social", and that "instead of the domination of nature, therefore, we must consider the more complex process of the *production of nature*".[25] For Smith, the term "second nature" captures the result of the historical, worldwide generalisation of production for exchange characteristic of capitalism, and subsequently the result of the "real subsumption of nature to capital".[26] With the constitution of the capitalist world market, "nature is progressively produced from within and as part of the so-called second nature".[27] In search of profit, capital "attaches a price tag to everything it sees and from then on, it is this price tag which determines the fate of nature"; "no part of the earth's surface, the atmosphere, the oceans, the geological substratum, or the biological substratum are immune from transformation by capital".[28] Indeed, for Smith, such was the degree to which capital had subsumed nature in this manner that the distinction between first and second nature was, by the late twentieth century, practically obsolete.[29]

[24] This argument would certainly seem to be consistent with Rioux's other work on corporeality, insofar as it critiques the commonplace, abstract category of "the natural body" and foregrounds, instead, the material processes of the social reproduction of real bodies under circumstances that are

Smith's next step in his line of argument is unequivocal: "Unless space is conceptualised as a quite separate reality from nature, the production of space is a logical corollary of the production of nature".[30] For Smith, the produced spaces and scales of capitalistic second nature emerge out of an incessant "dialectic of equalisation and differentiation" of the development of capital's productive forces. As capital extends its reach over the whole globe, the socio-ecological landscape is subsumed within a process that consists of capital's price tagging of everything. Yet this landscape comprises myriad particularised spaces/places—at a variety of spatial scales, including that of the national state. The *relative* past, present and future development of these spaces is conditioned by specific degrees of the concentration and centralisation of capital, the agglomeration and socialisation of labour-power, and differing degrees of resilience to the perpetual rhythms of accumulation and geographical "see-saws" in the location of investment that periodically threaten the devaluation of geographically concentrated fixed capital and of relatively immobile working classes bearing particular productive and cost attributes.[31] As Smith explains,

> the drive toward universality in capitalism brings only a limited equalisation of levels and conditions of development. Capital produces distinct spatial scales—absolute spaces—within which the drive towards

---

historically specific to capitalism, and which therefore engender the particular attributes of the "*labouring* body". See Sébastien Rioux, "Embodied Contradictions: Capitalism, Social Reproduction and Body Formation", *Women's Studies International Forum*, Vol. 48 (January–February 2015), pp. 194–202.

> equalisation is concentrated. But it can do this only by an acute differentiation and continued re-differentiation of relative space both within and between scales. The scales themselves are not fixed but develop (growing pangs and all) within the development of capitalism itself. They are not impervious; the urban and national scales are products of world capital and continue to be shaped by it. But the necessity of discrete scales and of their internal differentiation is fixed.[32]

"Uneven development", Smith concludes, "is the product and geographical premise of capitalist development".

This perceptive insight, we argue, ought to have significant methodological ramifications for the theorisation of the international, for if the appearance of "socio-political multiplicity" and of uneven international development as real spatial phenomena must be *explained* on the basis of their (re-)production as a moment of the real subsumption of nature to capital—that is, as *produced* spaces—then we ought to be prepared to accept the possibility that the international is less of an autonomous, autopoietic system than might be posited by means of some transhistorical logic or apprehended by an immediate empirical focus on geopolitical rivalry and cooperation. We should, in other words, be prepared to include "the international" among those other categories—ground-rent, landed property and agriculture—that Marx accepted as being central to any scientific analysis of pre-capitalist society and economy, but which become subsumed within the production of nature and space in specific, practical ways. In short, their categorial relation should be established on the basis of their determination and reproduction under capitalism *specifically* rather than on the basis of historical precedence. To paraphrase Marx, "Capital is the all-dominating economic power of bourgeois society. It must form the starting-point as well as the finishing-point, and must be dealt with before [the international]".[33]

The recognition that this insight today applies as much to the political categories of the national state and the international system as it does to economic categories is common among certain Marxist literatures—for instance, among "state derivation" theorists, and the various scholars associated with "open Marxism"—but is at odds with orthodox IR and traditional epistemologies of the international.[34] We should also already add at this point that it would appear to be inconsistent with Neil Smith's own take on the remaking of state-space in "post-national Europe", from which we quoted above, which also implicitly adheres to a methodologically nationalist epistemology and, in our view, fails to follow through the insight of his own production of space thesis into his conception of the contemporary national state form. Our contrasting methodological point here is made clear by Juan Iñigo Carrera, who explains how and why the world market historically results from the confluence of various national processes of capital accumulation, but, once this process is complete, the relationship becomes inverted and the world market becomes—both in a concrete and cognitive sense—"systematically prior" to its differentiation into national spheres in competition with one another which, through their antagonistic relationships as "hostile brothers",[35] *outwardly* mediate the unfolding of the essentially global *inner* determinations of the production of relative surplus-value on a planetary scale.[36] Whatever the "fact" of a multiplicity of national state spaces formally constituted under pre-capitalist or mercantilist phases of international economic integration, then, these spaces are *today* reproduced organically as both product and pre-condition of the essentially *global* accumulation of capital—that is, as "really subsumed" elements of capital's "second nature".[37]

---

[32] *Ibid.*, p. 196.

[33] Karl Marx, *Grundrisse* (Harmondsworth: Penguin, 1973), p. 108. Marx goes on to say: " … It would therefore be unfeasible and wrong to let the economic categories follow one another in the same sequence as that in which they were historically decisive. Their sequence is determined, rather, by their relation to one another in modern bourgeois society, which is precisely the opposite of that which seems to be their natural order or which corresponds to historical development. The point is not the historical position of the economic relations in the succession of different forms of society … Rather, their order within modern bourgeois society".

[34] See, for example, Claudia von Braunmühl, "On the Analysis of the Bourgeois State within the World Market Context", in John Holloway and Sol Picciotto (eds.), *State and Capital: A Marxist Debate* (London: Edward Arnold, 1978), pp. 160–177; John Holloway, "Global Capital and National State", *Capital & Class*, Vol. 18, No. 1 (1994), pp. 23–49; Werner Bonefeld, "The Spectre of Globalization: On the Form and Content of the World Market", in Werner Bonefeld and Kosmas Psychopedis (eds.), *The Politics of Change: Globalization, Ideology and Critique* (Basingstoke: Palgrave, 2000), pp. 31–68; and Peter Burnham, "Marx, International Political Economy and Globalisation", *Capital & Class*, Vol. 25, No. 3 (2001), pp. 103–112.

As path breaking as Smith's argument was for its time, we think that there are further limitations to his theory of uneven development. Crucially, Smith works with a methodological approach that reinforces a dualistic rift between theory and history (ironically so, given the attention he gives to the unity of nature and society). For Smith, as with historical-geographical materialist scholarship more generally, theorising amounts to offering a mental construct, or "cognitive map",[38] that identifies general tendencies or "laws of motion" in abstraction (e.g. "the dialectic of equalisation and differentiation"), only to then attempt to extrinsically *apply* that construct or map to an otherwise self-subsisting concrete "reality" in order to try to come up with a framework offering a certain degree of explanatory power. The crux for us is that, in dialectical cognition, "theoretical categories" are not—in a Kantian dualistic fashion—a subjective way of ideally organising a given material content, but rather they are more abstract yet fully objective determinations of those more concrete "empirical" forms. This further explains our earlier injunction to heed Marx's methodological point about the determinate—rather than historical or logical—sequencing of the categories of critique.[39] Smith, on the other hand, is himself culpable of a dualism between theory and history. To the extent that he in particular conceives of unity of the world market, it is but the *contingent* result of the *in*determinate manner in which the tendencies of "equalisation and differentiation" unfold historically and concretely.[40] To the extent that he conceives of national states as mediating forms of worldwide capitalist development, they are but the contingent "resolution" of the *in*determinate manner in which the tendencies of "competition and cooperation" unfold historically and concretely within and beyond their demarcated boundaries.[41] In both cases, his "mapping" remains at the apparent level of the concrete forms in which the substantive immanent unity of the global movement of the total social capital—to which we return in more detail below—asserts itself outwardly through the antagonistic relationships among individual capitals (economically) and among national states (politically). That is, his work leaves significant questions unanswered regarding the development of an approach that can adequately conceive of the systematic mediations between abstract tendencies of the capital accumulation process and concrete empirical forms of the world market.[42]

---

[35] Karl Marx, *Theories of Surplus Value, Vol. II* (Moscow: Progress Publishers, 1968), p. 29.

[36] Juan Iñigo Carrera, "The General Rate of Profit and Its Realisation in the Differentiation of Industrial Capitals", in Greig Charnock and Guido Starosta (eds.), *The New International Division of Labour: Global Transformation and Uneven Development* (Basingstoke: Palgrave, 2016), p. 36.

[37] Further textual evidence to demonstrate that this accords with Marx's own thinking might be found in chapter 31 of *Capital*, where he discusses the "colonial system" as a concrete form of the original accumulation of capital: it "proclaimed the making of profit as the ultimate and sole purpose of mankind" (Karl Marx, *Capital: Volume I* [Harmondsworth: Penguin, 1976], p. 918). That is, now profit-making becomes the content of the social process of humanity as a whole (i.e. the world market), and not just any particular national community. Space constraints do not allow us to elaborate on the precise nature of the process of transition this entails in different parts of the world, but we would broadly endorse the approach in Dale Tomich, "Rapporti sociali do produzione e mercato mondiale nel dibattito recente sulla transizione dal feudalesimo al capitalismo", *Studi Storici*, Vol. 21, No. 3 (1980), pp. 538–564.

[38] David Harvey, *The Urban Experience* (Oxford: Blackwell, 1989), p. 2. We also think Castree's encapsulation of Harvey's theoretical project applies as much to Smith, insofar as "he acknowledges that while [theory] is indubitably *about* the world it is not, by definition, *coterminous with it*. … What this means is that while critique can be compelling *at the theoretical level*, it is found wanting when put to the test of conjunctural specifics"; Noel Castree, "The Detour of Critical Theory", in Noel Castree and Derek Gregory (eds.), *David Harvey: A Critical Reader* (Oxford: Blackwell, 2006), p. 260. In this respect, Derek Kerr's critique of a theory-history dualism in Harvey's work applies as much to Smith; see Derek Kerr, "The Theory of Rent: From Crossroads to the Magic Roundabout", *Capital & Class*, Vol. 20, No. 1 (1996), pp. 70–71.

In sum, we find that Smith's "cognitive mapping" leads him to overlook the determinate social content of uneven development. At one point in *Uneven Development*, he does discuss the "fate of human nature under capitalism", but only as an incidental *by-product* of the technical division of labour and the historical advance of the system of large-scale machinery.[43] Smith does not, in other words, identify the development of the material powers of the human being as a labouring subject—that is, of human productive subjectivity—as the *content* of the production of nature, the real subsumption of nature to capital, the historical development of the social and technical division of labour, and of the development of the productive forces under capitalism. And for this reason, he too leaves us bereft of a unified theory that is able to provide a systematic explanation of uneven international development that maintains the unity of not just nature and society but also theory and history. As we now explain in further detail, the key to finding such a theory still lies precisely in the "inner dynamics of development itself", as suggested by Rioux. But it entails the foregrounding of the recognition that the global accumulation of capital still rests upon the pursuit of relative surplus-value, and with it the transformation of the human productive subjectivity of the international working class.

---

[39] John Bellamy Foster makes a broadly similar point in his "Marxism in the Anthropocene: Dialectical Rifts on the Left", *International Critical Thought*, Vol. 6, No. 3 (2016), p. 414.

[40] See, for instance, Smith, "The Geography of Uneven Development", *op. cit.*, pp. 189–190.

[41] See Smith, "Remaking Scale", *op. cit.*, pp. 228–229.

[42] In *Uneven Development*, Smith falls back on orthodox Marxist ideas on the sources of uneven international development and "underdevelopment" (the likes of Samir Amin, Arghiri Emmanuel and Ernest Mandel), and only re-signifies them in light of his foregrounding of a dialectic of equalisation and differentiation. For a critique of this orthodoxy, see Juan Iñigo Carrera, "End Notes to 'The General Rate of Profit and Its Realisation in the Differentiation of Industrial Capitals'", available: <https://www.academia.edu/24332230/End_Notes_to_The_general_rate_of_profit_and_its_realisation_in_the_differentiation_of_industrial_capitals_1> (accessed 7 October 2016).

[43] Smith, *Uneven Development*, *op. cit.*, pp. 72–74.

The Global Accumulation of Capital and the "Inner Dynamics of Development Itself"

One of Marx's most potent scientific discoveries was that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (such as a firm), nor a social grouping sharing common characteristics and interests (for instance, "business" or "the bourgeoisie"). Rather, in its general determination as self-valorising value, capital is a materialised social relation between commodity-owners differentiated into social classes, which, in its fully developed form as the (global) *total social capital*, becomes inverted into the (alienated) subject of the process of social reproduction and its unitary expansion.[44] Thus, capital is essentially the movement of the self-expansion of the objectified general social relation between private and independent human beings, which, in the course of its own process, produces and reproduces the latter as members of antagonistic social classes.[45] All moments of the human life-process become inverted into material bearers of the life-cycle of capital, or, rather, they become forms assumed by the flow of value in its self-expanding circulatory process. Subsumed under the capital-form, the alienated content of social life becomes the production of surplus-value or the formally boundless quantitative progression of the general reified form of social-ecological metabolism.[46]

Although this content governs the movement of capital as a whole, as an alienated collective power the total (global) social capital is nonetheless the product of the private and independent form taken by social labour.[47] The general unity of the movement of the total social capital cannot be established immediately. It is thereby indirectly established through the exchange of commodities resulting from the apparently autonomous actions of individual capitals in competition with each other, as each of them pursues the maximisation of its profitability through the expanded reproduction of their formally independent cycles of valorisation. More specifically, the concrete form in which individual capitals assert their class unity as "aliquot parts" of the total social capital is the process of formation of the general rate of profit.[48] This is the inner or essential determination of the general social relation between capitalist firms (or individual capitals). Competition between individual capitals operating in different branches of production within the international division of labour (IDL) has the result of equalising rates of profit in and across those branches, thus averaging out to form an average world market rate of profit.[49]

The antagonistic character of the class relation disrupts the fluidity of the total social capital's valorisation. The establishment of the general unity of social labour must therefore take shape through a further objectified form of social mediation, the state, which in bourgeois society confronts commodity-owners (the personifications of money-as-capital and of the commodity labour-power), as an apparently external power with the authority and capacity to establish the overall direct regulation of their antagonistic social relations. The state thus develops as the most concrete political form that embodies the direct organisation of the unity of the conditions of social reproduction in its alienated capital-form.[50] By virtue of this content, the state becomes the general political representative of the total social capital. In brief, capitalist social relations exist as differentiated economic forms (the autonomised movement of capital-commodities on the market) and political forms (class struggle and the state). The latter, far from enjoying "autonomy" (relative or otherwise), are the necessary mode of realisation of the contradictory content of the economic mode of existence of capitalist social relations. In other words, class struggle and state policies are not to be conceived of as independent, self-subsisting factors that externally modify or influence the workings of the law of value. Instead, they need to be grasped as necessary modes of motion through which the law of value further unfolds beyond the strictly economic forms immediately springing from the indirect nature of the social relations of capitalist production.

[45] *Ibid.*, pp. 723–724; Karl Marx, *Capital: Volume II* (Harmondsworth: Penguin, 1992), p. 185.

[46] Marx, *Capital: Volume I*, *op. cit.*, pp. 251–257.

[47] The term "total social capital" is the usual English translation of what Marx variously terms "*gesamte gesellschaftliche Kapital*", "*gesellschaftlichen Gesamtkapitals*", or simply "*gesellschaftliche Kapitals*".

[48] Karl Marx, *Capital: Volume III* (London: Penguin, 1981), pp. 298–300, 312.

[49] Iñigo Carrera, "The General Rate of Profit", *op. cit.*; Bonefeld, "The Spectre of Globalization", *op. cit.*, p. 38.

Insofar as the law of value operates through the jurisdictional demarcation of the world market into multiple national spaces of valorisation, the unity of the global total social capital becomes self-differentiated into the circulation processes of distinct national total social capitals. In this way, the competition between individual capitals becomes politically mediated "by the direct relations that are established between distinct national states—that is, their 'international relations'".[51] The formation of the average world market rate of profit thus takes concrete shape through diverse geopolitical forms. However, this does not change the fact that the immanent content of both international economic relations between individual capitals and international political relations between national states remains the accumulation of capital on a world scale. Geopolitical competition in the "interstate system" is thus but a further mediated form in which, through their political representation by their respective states, the "multiplicity" of national total social capitals also assert their unity as aliquot parts of the global total social capital. Through all these complex mediations, the latter thereby affirms itself as the concrete alienated subject of socio-ecological metabolism through the exploitation of the international working class.[52]

This eminently unconscious and crisis-ridden social-ecological process gives rise to changing constellations of the international division of labour and, as a consequence, to evolving developmental potentialities for each national space that mediates the production of relative surplus-value by the total social capital across the globe. The territorial or spatial dimension of the capital accumulation process—and the changing forms of the worldwide division of labour—therefore cannot be seen as being determined by the conscious and autonomous political "strategies" of governments and state bureaucrats charged with directing the "national economy". Instead, it needs to be grasped as an expression of the underlying formal and material unity of the essentially global contradictory dynamics of the accumulation of the total social capital through the production of relative surplus-value, which are economically mediated (as opposed to determined) by relations of competition among individual capitals like transnational corporations (TNCs), on the one hand, and politically mediated by the policies of a multiplicity of national states on the other.[53]

[52] For further methodological clarification of the relation between the *global* total social capital and *national* total social capital, see *ibid.*, pp. 56–59.

The dynamic and changing character of international development is therefore a product of *these* "inner structural dynamics" of the accumulation of capital and the worldwide production of relative surplus-value in particular. Smith's insistence that "uneven development represents a forced yet contested, momentarily fixed yet always fluid resolution to [the] central contradiction [of equalisation and differentiation]" ultimately stops short of foregrounding the content of such dynamics, and thus leaves "geo-historical processes as they are 'really going on'" unexplained.[54] Where we advance beyond Smith, therefore, is in our own insistence that we need to return to the question of how the total global social capital—as the general reified form of social-ecological metabolism—looks to produce relative surplus-value *in concrete, historical forms*. The key to providing an answer to this question, and one which evades the dualism between theory and history, lies in the recognition that in its most developed form as large-scale industry, the production of relative surplus-value fundamentally entails the permanent revolution in the modes of exertion of the labour-power of individual workers and of their articulation as a directly collective productive body or organism.[55] *This* is the "permanent revolution" that lies at the heart of the changing historical forms of the international division of labour and its geopolitical manifestations, and which—when it forms the basis of the theorisation of "the international"—allows for the preservation in the very process of cognition itself of the unity of nature and society (i.e. the specificity of capitalism) as well as the unity of theory and history in the substantive explanation of the social totality and its changing forms.

The foundation of the uneven spatial differentiation of capitalism as a totality—whether manifest in the differentiation of conditions of development across and indeed *within* national borders—must therefore be searched for in the global, historical transformation of the material forms of the capitalist production process (and not, as Smith would leave it, in some indeterminate dynamic of equalisation and differentiation). To reiterate, the (global) total social capital's production of relative surplus-value through the transformation of the materiality of labour process, and hence of the productive subjectivity of the labourer herself, is the general content that is realised in the form of uneven development.

The Changing Forms of the New International Division of Labour and Uneven Development Today

Uneven development is the product of the total social capital's drive to enhance the production of relative surplus-value on a world scale through the development of the productivity of labour. Today, this drive finds its most advanced expression in the computerisation and robotisation of large-scale industry. As a result of its own immanent tendencies, the contemporary form of the IDL represents a complex constellation that is the culmination of an evolving concrete historical process, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class (through their impact upon their general conditions of reproduction and condensed in what Marx alludes to as the "historical component" of the value of labour-power). Each country therefore *tends* to concentrate a certain type of labour-power of distinctive "material and moral" productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner.[56] Production in specific industrial branches since the 1950s, and more conspicuously since the 1970s, has thereby expanded in some countries while contracting in others where new and more advanced sectors have developed, following a rhythm determined by the evolution of technological changes and the relative cost and productive attributes of national labour forces.[57] The result of this historical process is the contemporary IDL, which is expressed of course in "socio-political multiplicity" and the immediate fact of uneven development.

---

[53] This crucial point about dialectical mediation is lost in dualist accounts of international politics that posit a "logical" separation between geopolitics and capitalist development – see, for instance, David Harvey, *The New Imperialism* (Oxford: Oxford University Press, 2003). Furthermore, this points to how the crisis-ridden nature of capital accumulation intensifies geopolitical competition to the point of it taking the form of military rivalry between national total social capitals. Although this does not add anything to the *explanation* of the content of the determinations at stake, it does draw attention to its concrete forms and, in particular, to those that comprise the focus of many of the case studies chosen by the U&CD literature.

[54] Smith, "The Geography of Uneven Development", *op. cit.*, pp. 190, 193.

[55] Marx, *Capital: Volume I*, *op. cit.*, p. 617.

Succinctly put, our argument is therefore that the essential general content that explains the unevenly developed character of the contemporary IDL, and which has been reproduced under its evolving historical configurations since the 1950s until the present time, consists in the international fragmentation of the productive subjectivity of the working class.[58] Our approach allows us not just to explain the existence of the international as comprising a multiplicity of distinct national forms of the organisation and reproduction of a material and essentially global process, but also to explain the changing forms of this IDL in world-historical terms.

An analysis of the materiality of the process through which the total social capital today organises socio-ecological metabolism in the form of large-scale industry reveals four divergent and ongoing tendencies in the development of the productive attributes of the global working class.[59] First, it expands the productive subjectivity of the part of the collective labourer responsible for the advance in the conscious control of the movement of natural forces (that is, science) and its technological applications in the directly social organisation of the immediate production process. Although not explicitly addressed by Marx in *Capital*, the benefit of historical hindsight makes it very easy for us to recognise how capital deals with its constant need for the development of the productive powers of science and for the conscious organisation of the increasingly social labour process, namely by engendering a special partial organ of the collective labourer.[60] Capital requires from these workers ever more complex forms of labour. As much as those discussed in *Capital*, these are also "immediate effects of machine production on the worker".[61] Needless to say, inasmuch as this expanded productive subjectivity is nothing more than a concrete form of the production of relative surplus-value, the exercise of the newly developed intellectual productive powers is inverted into a mode of existence of capital in its movement of self-valorisation as well. Moreover, sooner or later many of these intellectual dimensions of living labour can also experience automation (or knowledge "codification") and therefore become relatively simplified. This latter aspect has been central to the more recent phases of the evolution of a "new" international division of labour (NIDL), which has therefore subsumed intellectual labour under its dynamics too.[62]

[57] A process whose incipient stages were identified and (problematically) theorised by Folker Fröbel, Jürgen Heinrichs and Otto Kreye, *The New International Division of Labour: Structural Unemployment in Industrialised Countries and Industrialisation in Developing Countries* (Cambridge: Cambridge University Press, 1980).

[58] Iñigo Carrera, *El capital*, *op. cit.*, pp. 53–90.

[59] *Ibid.*; Guido Starosta, "Revisiting the New International Division of Labour Thesis", in Charnock and Starosta, *The New International Division of Labour*, *op. cit.*, pp. 79–103.

Secondly, the process tends to degrade the subjectivity of those workers that acquire and exercise their increasingly simpler manual or experienced-based productive attributes in the direct process of production. Indeed, large-scale industry is based on the objectification of tacit knowledge, previously embodied in the manual industrial worker and largely acquired through lengthy on-the-job, learning-by-doing processes, as an attribute of the system of machinery.[63] In this sense, the tendency of the impact of the capitalist automation is certainly one of "deskilling" or "degradation" of direct production work through the objectification of formerly manual tasks as functions of machines. Yet the effect of increasing automation in recent decades has not only been one of deskilling. It has been mixed, also entailing a certain creation of new skills that are required by capital even from direct production workers. The key point, however, is that these newer skills have been of a different *kind* from those that have been eroded. While these latter skills tended to be based on the *particularistic* development of the productive subjectivity of wage-workers (both manual and intellectual) as a result of the practical experience of machining in the direct process of production, the newly created skills tend to revolve around the *universalistic* dimension of the productive quality of labour-power, whose development is achieved in the general process of education and socialisation that precedes its actual application in the production process. For instance, the "microelectronics revolution" that is at the basis of the contemporary international division of labour has entailed not only the degradation of the particularistic dimension of direct production work but also the emergence and generalisation of so-called "soft" or "generic skills",[64] such as familiarity with computers and flexibility or individual initiative in problem-solving or decision-making.[65]

[65] Margherita Balconi, "Tacitness, Codification of Technological Knowledge and the Organisation of Industry", *Research Policy*, Vol. 31, No. 3 (2002), pp. 357–379.

In the third place, while the new technologies have not resulted in the total elimination of manual labour from automated processes of production,[66] they have recreated the conditions for the extended reproduction of what Marx called the "modern manufacturing division of labour", that is those non-mechanised tasks and labour processes acting as an "external department" of large-scale industry proper as the dominant form.[67] This tendency was fundamental for the initial stages of what scholarly debate labelled an NIDL from the late 1960s, and it remains the focus of continuing critical research on "commodity chains" and the labour process in, for instance, the global garment industry.[68]

Fourthly and lastly, the production of relative surplus-value through the system of machinery leads to the multiplication of the surplus population relative to the needs of the accumulation process, which also constitutes a transformation of productive subjectivity produced by the automation of large-scale industry.[69] More specifically, this tendency represents the most extreme case of material mutilation of the productive attributes of the working class resulting from capital accumulation, that is, not simply their degradation but the prospect of their outright non-reproduction. Yet it is from this tendency that the global pool of cheap but disciplined labour-power that has been central for the original constitution and evolution of an NIDL from the 1960s was eventually derived, and which today provides the lifeblood for "debtfarism" and the "poverty industry" in advanced as well as developing countries.[70]

In sum, the upshot of all these material transformations in the capitalist labour process has been an increase in the internal polarisation of the global collective labourer according to the type of productive attributes that its different members embody. As a concrete expression of the inner nature of the process of capital accumulation, these social processes have been global in content and national only in form. More specifically, this growing differentiation of the productive attributes of the collective labourer of large-scale industry has been at the basis of the emerging patterns of differentiation of national and indeed supra- and sub-national spaces of accumulation in the last four decades. In effect, based on these productive changes and the revolution in communication and transportation methods, capital has been increasingly able globally to disperse the different parts of the labour process according to the most profitable combinations of *relative* costs and productive attributes of the different national fragments of the worldwide labour force (through their impact upon labour productivity and unit labour costs). In empirical terms, this presents itself in the immediate fact of uneven international development.[71] It is also manifest in the internal regional and local differentiation of the conditions of the reproduction of labour-power *within* national spaces of accumulation,[72] as well as the formation of wider supranational or regional spaces of valorisation whose constitution thereby required the mediation of the development of novel international juridical and political forms (e.g. the European Union). The economic and/or political integration of national spaces of accumulation into broader free trade areas, in competition with one another, has been yet another concrete form in which capital achieved the increased heterogeneity in the reproduction of the varied organs of the global collective labourer.

[72] Which is to say that the divergence in the conditions of reproduction of the expanded and degraded organ of the collective labourer is now replicated *inside* advanced capitalist countries

We would underline, however, that the historical emergence and expanded reproduction of this novel form of the IDL has not entirely wiped out its "old" or "classic" modality. In this, certain countries (for instance, most of the Southern Cone of Latin America and, paradigmatically, Argentina and Brazil), due to particularly favourable and non-reproducible natural conditions that enhance the productivity of labour, continue to participate in the planetary production of relative surplus-value through the provision of cheapened raw materials, staple foods or energy sources to the world market (hence directly or indirectly reducing the average value of labour-power of the international working class).[73] Moreover, the reproduction of this form of subsumption of these territories into the global circuits of accumulation is not simply based on the export of "natural-resource based" commodities. In effect, insofar as the latter are material bearers of ground-rent and are consumed overseas, this involves a continuous in-flow of extraordinary social wealth that constitutes a drain of the total surplus-value otherwise available for capital's appropriation, and which, *ceteris paribus*, would end up in the pockets of domestic landowners.[74] Capital was thus historically driven to overcome this barrier to its accumulation capacity by reshaping those spaces of valorisation in order to recover part of that surplus-value, through the establishment of an "antagonistic association" with local landowners over the shared appropriation of ground-rent.[75] Thus, from originally being simply a source of cheap raw materials and means of subsistence, the qualitative specificity of those national spaces of valorisation has actually become determined as a source of ground-rent recovery for global capital.[76]

The reproduction of this modality of the accumulation process needs to be politically mediated by a wide array of state policies that intervene in the circulation of ground rent-bearing commodities in order to block the "spontaneous" course of ground-rent towards landowners and divert its flow towards capital. Thus, the transfer of ground-rent must be achieved through different policy mechanisms

---

themselves. This process is, of course, heavily mediated by gender, ethnicity, age and other intersectionalities. See, for example, the illustrative evidence in Alex Nunn, "The Production and Reproduction of Inequality in the UK in Times of Austerity", *British Politics*, Vol. 11, No. 4 (2016), pp. 469–487.

[73] As Marx remarks in Volume I of *Capital* (*op. cit.*, pp. 579–580), the establishment of this "classic" modality of the IDL was determined by the production of relative surplus-value through the system of machinery of large-scale industry.

[74] Juan Iñigo Carrera, *La renta de la tierra: Formas, fuentes y apropriación* (Buenos Aires: Imago Mundi, 2017).

[75] Nicolas Grinberg and Guido Starosta, "From Global Capital Accumulation to Varieties of Centre-Leftism in South America: The Cases of Brazil and Argentina", in Susan J. Spronk and Jeffrey R. Webber (eds.), *Crisis and Contradiction: Marxist Perspectives on Latin America in the Global Political Economy* (Leiden: Brill, 2015), pp. 236–272.

[76] For an explanation of the specific modality through which subsidiaries of TNCs operate within such countries, and how they valorise on the basis of the recovery of in-flows of surplus-value, see Alejandro Luis Fitzsimons and Guido Starosta, "Global Capital, Uneven Development and National Difference: Critical Reflections on the Specificity of Accumulation in Latin America", *Capital & Class*, Vol. 42, No. 1 (2018), pp. 109–131.

(overvalued exchange rates, export and import taxes, direct state regulation of staple food and raw material prices, etc.), which result in the establishment of specific domestic conditions for the circulation of capital within those national territories.[77] Consequently, its appropriation can only be done by capitals operating within those countries and whose circuit realises its final phase (i.e. the sale of commodities) almost exclusively on protected domestic markets of a very limited size vis-à-vis world market norms.[78] Although this means that individual capitals cannot reach the scale needed for profitably utilising advanced technological conditions, they have compensated the resulting higher production costs with the appropriation of a portion of ground-rent. In this way, they have valorised at the average rate of profit despite their restricted magnitude and backward technologies.[79] This abundant extraordinary mass of social wealth has thus systematically complemented the surplus-value extracted from the domestic working class to the point of determining the very specificity, *with its inherently limited potentialities*, of the developmental trajectory in those national spaces. This, in other words, explains "underdevelopment" in Latin America, and on a basis that is entirely consistent with the "unified theory" of uneven development we outline above.

The emergence and development of the "new" IDL did not, therefore, entail the overcoming of the "classic" IDL. Both modalities actually coexist in the contemporary configuration of the world market, resulting in a more complex form through which the formal/material unity of the global accumulation process is achieved. This insight can explain the content that underlies the different types of regionalism that prevail in Latin America for instance (e.g. the Mercosur), and in a way that does not simply rely on a catch-all tendency to subsume the explanation of the existence of such regions within some abstract logic of geopolitical rivalry and cooperation. It is, in other words, another reason not to theorise "the international" as if political forms were autonomous from their economic content.

Conclusion

In a recent essay, Olaf Corry makes the case that the longstanding preoccupation with geopolitics among IR scholars of various theoretical bents has resulted in a commonplace tendency to assert an ontological distinction between nature (or the environment), on the one hand, and questions of "sovereignty, anarchy and balance of power" on the other—a separation he finds palpably untenable in an "Anthropocene age" in which we are all fast becoming aware of the mutually transformative (and destructive) dynamics of human behaviour and the Earth's ecology.[80] Corry suggests that "old materialism" might have something to offer IR scholars today insofar as "Marx put nature, and human interaction with it, right at the centre of historical social theory".[81] We agree, and have sought in

this article to outline the basis for a unified—that is *dialectical*—theory of uneven development that resists any tendency to posit a dualist logic between humans and nature, or indeed between the "laws of motion" of capital and the international system. The key to this endeavour, we suggest, is to put the question of the transformation of human productive subjectivity—or, more simply, labour—at the heart of any cogent theory of the international and its uneven development. Unfortunately, while Rioux is right to suggest that Neil Smith has gone some way to uncovering the "inner dynamics of development itself", we have argued that Smith's explanation of uneven development on the basis of his theory of the production of nature, space and scale in capitalism falls short of foregrounding the underlying content of uneven development: the worldwide production of relative surplus-value and, with it, the transformation and fragmentation of the productive subjectivity of the international working class.

To persist in the pursuit of a theory of uneven development and the international that upholds the relative autonomy of geopolitical and sociological modes of explanation on the basis of an axiomatic "logical rule" is to foreclose the possibility of arriving at a socio-naturally-grounded theory that explains why and how the inner dynamics of (specifically) capitalist development are *necessarily* uneven, and why and how they are expressed through the reproduction in time and space of an international state system characterised by cooperation and conflict between geopolitical forms that mediate the global accumulation of capital. Our intervention goes some way, we hope, towards the elaboration of such a theory—one that foregrounds the analytical and political question of the transformation of human productive subjectivity. As a basis for future research and debate into the dynamics of uneven development, and their mediation by different national states, our intervention points towards further empirical investigation of the concrete forms in which the expansion and degradation of the productive subjectivity of the different organs of the collective labourer, as it springs from the global production of relative surplus-value, unfolds.

Global capital, uneven development and national difference: Critical reflections on the specificity of accumulation in Latin America

Alejandro Luis Fitzsimons
Universidad Nacional de Quilmes, Argentina

Guido Starosta
Universidad Nacional de Quilmes, Argentina

Abstract

A recent Special Issue in this journal devoted its pages to discuss the varied forms of capitalist development in different countries and regions across the globe. Specifically, the contributions offered a critical assessment of the hegemonic 'neo-institutionalist' approach to the study of national diversity of capitalism, with particular focus on the 'varieties of capitalism' approach. This article critically engages with the different alternatives to the varieties of capitalism approach that were put forward and shows that these other perspectives also fall short of providing a convincing framework to address the problematique of national or regional particularities as posed in the debate. In order to offer a more solid explanation of the phenomenon of 'capitalist variety', the article draws upon Marx's fundamental insight into the determination of capital as a materialised social relation which becomes the immediate alienated subject of the organisation of the process of social life and also moves some way beyond it so as to cast fresh light on global transformation and uneven development in recent decades. More concretely, the article further submits that the specificity of the Latin American 'variety of capitalism' must be grounded in the constitution and dynamics of the

international division of labour which results from the underlying essential unity of the production of relative surplus value on a world scale by the global total social capital. In other words, we grasp the emergence of national specificities as the immanent result of the global unfolding of the 'law of value'.

Keywords
global accumulation, Latin America, law of value, uneven development, varieties of capitalism

Introduction

A recent Special Issue in this journal devoted its pages to discuss the varied forms of capitalist development in different countries and regions across the globe. Specifically, the contributions to the Special Issue offered a critical assessment of the hegemonic 'neo-institutionalist' approach to the study of national diversity of capitalism, with particular focus on the 'varieties of capitalism' (hereafter, VoC) school (Hall & Soskice 2001), which is probably the most influential perspective within the broader 'comparative capitalisms' (CC) literature (Coates 2015: 14–16). The general conclusion agreed upon by most authors was that this approach suffers from several weaknesses for the purpose of a critical understanding of the undeniable national differences that exist in the global landscape of the capitalist mode of production. On the other hand, participants in the debate also tended to agree that there is a 'rational kernel' in the intellectual enterprise underpinning the VoC approach, which is the recognition that it is necessary to account for the self-evident differences in the contemporary forms taken by capitalism within each national or regional space of capital accumulation. However, disagreements emerged when it came to establishing the alternative approach that could offer a more solid explanation of the social processes underlying the phenomenon of national differentiation in the world market.

A further point made in the Capital & Class Special Issue was that although the original focus of the VoC perspective was on diversity in 'advanced' capitalist countries, it later broadened its analyses to incorporate research on other parts of the world (Ebenau 2015).[1] As a matter of fact, one of the central themes that cropped up in most articles in a specially devoted section on zones outside the 'core' of the capitalist world economy was the inability of the VoC framework (and also of the broader CC literature) to offer a solid account of the particularities of development in 'peripheral' or 'emergent' countries or regions. Moreover, most contributions also tended to agree on the fundamental reasons behind the failure of 'neo-institutional' perspectives to shed light on the nature and dynamics of the 'periphery'. In the first place, critics highlighted that the one-sided focus on *institutions* led the VoC approach to neglect the specifically *capitalist* character of those societies. Second, they also argued that it failed to shed light on the ways in which the global dimension of capitalist social relations shapes the structure and trajectory of those countries and regions of the world economy.

We fully concur both with this appraisal of the limitations of the neo-institutionalist approach to our understanding of the 'periphery' and with the main sources of those weaknesses that these critics of the VoC identified. However, we think that the radical alternative frameworks advanced in the Special Issue, based as they were on different versions of dependency theory and on the increasingly popular uneven and combined development (U&CD) perspective, did not entirely succeed in overcoming those limitations of the VoC school to make sense of the specifically capitalist and global determinations underlying the constitution of the political economy of the so-called 'periphery'.

In this regard, the central aim and deliberately limited scope of this article is to intervene in this other 'derivative' debate, specifically focusing on the question of the 'variety of capitalism' prevailing in Latin America (which, incidentally, was one of the most widely discussed cases in the Special Issue).[2] Thus, while taking on board the consensus on the pitfalls of neo-institutionalism that emerged out of the Special Issue, we intend to push the discussion forward by critically engaging with the different alternatives to the VoC approach that were set forth and show that these other perspectives also fall short of providing a convincing framework to address the *problematique* of national or regional particularities as posed in the debate. In a nutshell, we argue that there are two main weaknesses in all those other approaches, which underlie their inability to offer a critical alternative to the understanding of the fundamental issue at stake. In the first place, despite their self-conscious effort to transcend the 'methodological nationalism' characterising the VoC perspective, they nonetheless fail firmly to ground the constitution of national or regional specificities in the essentially global dynamics of the capital accumulation process. Second, and relatedly, in all cases they more or less explicitly conceive of political forms of capitalist social relations, that is, class struggle and/or the state (and its policies) as somehow autonomous from the (alienated) economic content of this historically specific mode of existence of the human-life process: the self-movement of valorisation of value.

To overcome these shortcomings, this article offers an alternative approach that builds on innovative theoretical scholarship that has emerged in the last 20–25 years under the auspices of the Centre for Research as Practical Criticism (CICP), based in Buenos Aires, Argentina, and especially the work of the independent scholar Juan Iñigo Carrera (2007a, 2013). This work, which is only just recently beginning to appear in Anglophone literatures – in part, because it has been developed outside of formal academic structures and networks – represents a thorough re-examination of Marx's critique of political economy and its dialectical-methodical foundations (Iñigo Carrera 2006, 2014, 2015). While drawing upon Marx's fundamental insight into the determination of capital as a *materialised* social relation which becomes the immediate alienated subject of the organisation of the process of social life in its immanent unity, it also moves some way beyond it so as to cast fresh light on global transformation and uneven development in recent decades.[3]

Two insights from this reading of the Marxian critique of political economy are relevant for this purpose. First, we argue that the specificity of the Latin American 'variety of capitalism' must be grounded in the constitution and dynamics of the international division of labour which result from *the underlying essential unity of the production of relative surplus value on a world scale by the global total social capital* (Iñigo Carrera 2016b; Starosta 2016). In other words, we propose to grasp the emergence of national specificities as the immanent result of the global unfolding of the 'law of value'. Second, we submit that the qualitative form of capital accumulation in Latin America that has historically consolidated out of the global process of production of relative surplus value, and which is still being reproduced in the majority of countries in this region under the contemporary configuration of the international division of labour, revolves around the appropriation of an extraordinary mass of social wealth flowing into those national spaces of valorisation under the form of ground-rent (Caligaris 2016; Iñigo Carrera 2006, 2007b).[4] It is this specific determination which underlies the economic and political forms that constitutes the Latin American 'variety of capitalism'. However, the article also notes that since the late-1950s, the planetary production of relative surplus value has constituted a new, *co-existing* constellation of the international division of labour, which revolves around the international fragmentation of the productive subjectivity of the global collective worker of capitalist large-scale industry (Iñigo Carrera 2013: 53–90). The constitution of this so-called New International Division of Labour (NIDL) has been at the basis of the different developmental path followed by East Asian countries since the 1960s (Starosta 2016). But, in addition, the changes in Mexico and Central America in the last 30 years indicate that the *qualitative specificity* of their respective developmental processes has actually 'converged' with that of (second-tier) East and South East Asian newly industrialised countries (NICs) and 'diverged' from that of South American countries. Strictly speaking, then, one can no longer speak of a *single Latin American* 'variety of capitalism'.

To substantiate all these arguments, the article is structured as follows. The next section briefly reviews the main lines of criticism of the VoC that were put forward in the symposium and then moves to a more detailed appraisal of the other approaches that were presented as theoretical alternatives to neo-institutionalism. Upon uncovering the weaknesses of these radical approaches for the development of a solid *explanation* of the constitution and dynamics of the qualitative specificity of the developmental process in Latin America (or, more broadly, in the 'periphery'), the third section unfolds our own alternative approach to global uneven development based on our reading of the Marxian critique of political economy. This will allow us to delineate in greater depth the constitution and particular features of national spaces of valorisation with specifically limited qualitative potentialities (e.g. most Latin American countries), out the dynamics of the essentially global process of production of relative surplus value. Finally, the final section illustrates the more concrete implications of this perspective with the examination of the recent trajectory of the automotive sector in Argentina. This will allow us to bring to light the peculiarities of the form of accumulation of capital revolving around the appropriation of a portion of ground-rent (in a country which is paradigmatic of this modality of accumulation) through the observation of the immediate empirical manifestations of this form of valorisation of capital (in a sector of social production which, in turn, is emblematic of the limited potentialities of the industrialisation process to which the former gives rise). In addition, this brief 'sectoral case study' will serve to highlight more starkly the shortcomings of many of the other radical approaches to the study of Latin America.

Beyond the VoC approach? The limits of alternative critical approaches to the specificity of capital accumulation in 'peripheral' regions

The radical perspectives brought together in the Special Issue of this journal point to several weaknesses in the VoC approach to Latin America. Most of the critiques focus on its neo-institutional foundations, although some of them mention concrete problematic issues concerning the analysis of Latin America by VoC scholars. In the first place, as

Coates (2014: 21–24) points out, even within the CC literature it is increasingly acknowledged that the VoC approach pays scarce attention to the determinations of that whose varieties it aim to explain, that is, capitalism as an economic system. In this sense, some scholars have argued that the excessive emphasis on institutions led the VoC approach to 'reify' the different institutional arrangements as the only causes of national variation (Fernández & Alfaro 2011: 71; Taylor 2014: 131). Coates (2014: 24–25), however, goes further in his critique and observes that it is not simply a matter of complementing institutional with economic analysis, but a question of bringing the laws and tendencies of capitalism back into the heart of the explanation of differentiated national development.

This point dovetails with a second line of criticism made by several participants in the Special Issue: the underlying 'methodological nationalism' which characterises the VoC framework and institutionalism more generally. A first aspect of this is that the VoC approach is overly focused on the nation-state as a regulatory institution, losing sight of the growing role of supranational structures of regulation, such as bilateral or regional trade agreements, which limit state capacities for autonomous policy formulation and making (Ebenau 2012: 213–214). Similarly and with specific reference to Latin American countries, it has been argued that the VoC approach one-sidedly reduces the explanation of the behaviour of TNCs' subsidiaries to a function of the national institutional framework in which they operate, thereby overlooking their contextualisation within the *global* strategies of TNCs (Ebenau 2012: 211–212). Still, the farther-reaching criticism centres on the undertheorisation of the global economy. In effect, as noted by Taylor (2014), the VoC approach conceives of the world economy as 'as an aggregate of distinct national models' (p. 132), which leads these scholars to overlook the (hierarchical) interconnections between the diverse economies which form the global structure of capitalism (see also Ebenau 2014; Hardy 2014; Jessop 2014).

Finally, most critics have also taken issue with the VoC approach's 'firm-centrism'. In effect, this excessive focus on the firm, which derives from a general framework initially devised for the comparative analysis of advanced countries, fails to capture the central role of the state in the organisation of capitalism in Latin America (Fernández & Alfaro 2011: 80–84; Sánchez-Ancochea 2009). In a similar vein, the VoC approach is usually blind to the part played by working class resistance to transnational corporations' (TNCs') strategies, especially in the Argentine case (Fishwick 2014). Still, we think that the more problematic issue with the VoC's firm-centrism raised by critics lies elsewhere and is essentially methodological: the one-sided explanation based on 'agency' at the expense of 'structure'. More concretely, the argument of these scholars go, VoC's virtually exclusive focus on business strategies and forms of corporate governance does not allow it to comprehend the functioning of capitalism as a broader set of 'institutions' (or rather, social relations) which actually shape those strategies (Jessop 2014: 49–54).

In sum, although most critics recognise the merits of the VoC approach for drawing scholarly attention to the importance of national or regional particularities in the world economy, they also tend to agree that at bottom, the key weakness of the approach is that in its efforts to bring variety to light, it has neglected (or, at least, downplayed) the capitalist character of those societies in which those varied institutions that constitute their specificity are found. As Coates (2014) eloquently puts it,

> We cannot move from understanding to explanation without completing the epistemological rupture with the new institutionalism; without going from idealism to materialism, and without going from Weber to Marx. (p. 25)

We could not agree more with this. Hence, in the rest of this section, we turn to the critical examination of the major alternative approaches to the study of 'peripheral societies' that were put forward in the Special Issue of Capital & Class, to assess the extent to which they live up to Coates' demand to 'move from understanding to explanation' in the study of the specificity of Latin America in the global political economy of capitalism.

In broad terms, the Special Issue contained three main alternative perspectives for the critical study of the specificity of capitalism in 'peripheral' regions. The first one is that of Weiss, whose main thrust revolves around the recovery of ideas from the monthly review dependency school centred in turn on Baran and Sweezy's concept of 'economic surplus'. According to Weiss (2014: 160), this latter concept allows us to avoid the reification of institutions' characteristic of the VoC approach (i.e. the divorce of institutions from the relations of production which constitute their 'historical context'). In this sense, this author argues that institutional variety is always limited by the structural necessity to search for profits that define capitalism as a mode of production (Weiss 2014: 158). Thus, it follows that this first line of argumentation actually consists in *downplaying* the importance of the phenomenon of capitalist diversity rather than offering an alternative account of it. In the second place, Weiss (2014) points out that the *content* of institutional difference is not given by the need to resolve coordination problems of collective action, as VoC scholars would have it, but by the result of the *class struggle over the distribution of the economic surplus* (p. 162). However, despite this alternative conceptualisation of the content of institutions, Weiss does not seem to offer any source of national or regional capitalist diversity other than *institutional variety* itself. Put differently, Weiss' proposal comes down to the explanation of national specificities in terms of the different outcomes of the *politically determined modes of distribution* of the 'economic surplus'. However, it is to be noted that according to this approach, those national specificities do not imply any qualitative difference in the *economic content itself of the valorisation and accumulation of capital.* Variety, Weiss (2014) concludes, is simply defined as 'the historically conditioned and socially contested utilisation of economic surplus' (p. 165).

In our view, this approach fails to achieve a complete break with the institutionalist paradigm for at least two reasons. In the first place, similarly to the VoC framework, it still locates the explanation of capitalist diversity in the institutional configuration of different countries or regions. In effect, institutions are the only social forms that 'vary': the modalities of the valorisation and accumulation of capital that constitute the general content of the capitalist mode of production remain essentially the same in all 'national societies'. In the second place, in confining variation to a distributive conflict over the 'surplus', this perspective necessarily conceives of variety as a *contingent* feature of national or regional spaces of valorisation of capital, since all 'structural' economic determinations of the latter are seen as invariant by definition.

Ebenau (2012, 2014) offered a further alternative to the VoC approach to the study of the specificity of 'peripheral' societies in the world market, which also draws from the tradition of dependency theory. However, in this case the main intellectual source is the

Latin American school of dependency theory and centres on Cardoso and Faletto's analysis of the impact of external factors (grounded in each country's form of insertion in the world economy) on domestic class relations (Ebenau 2012: 219). On this basis, Ebenau highlights that there are certain structural factors – which originate in the dynamics of 'central' or 'dominant' countries – that condition the class struggle in 'dependent' countries and, a fortiori, their national processes of capital accumulation. These factors include, among others, the specialisation of dependent economies in the export of primary products, the hegemonic role of TNCs in the leading sectors of the local productive structure and the subordination of national capitals to the strategies of TNCs.

Now, a first critical point to make against this recovery of Cardoso and Faletto's contribution is that this 'sociological' version of 'dependency theory' focused on the class struggle as the essential explanatory factor of the Latin American specificity had already been challenged within the same theoretical tradition by its so-called Marxist current, that is, that derived from Ruy Mauro Marini's (1978, 2008) work. Although Ebenau does refer in passing to the works of Marini (Arinci et al. 2015: 193; Ebenau 2014: 110), he does not seem sufficiently aware of the crucial differences that set the latter apart from Cardoso and Faletto's more widely acknowledged 'sociological' take on dependency theory. Fundamentally, Marini (1978) perceptively noted that the version of dependency theory that 'pays lip service to the class struggle […] will never allow us to understand *why* the working class in advanced capitalist countries has managed to unfold its struggle with better outcomes than that of dependent capitalist economies' (p. 71, *our translation*). The reason for this inability resides in the fact that this approach invokes the class struggle as a self-grounded 'deus ex machina' which 'allows to explain everything' (Marini 1978: 68). In contrast, Marini's (1978) alternative perspective consists in identifying the *reasons* that 'explain the class struggle', that is, it investigates 'the material conditions in which the class struggle takes place' (p. 68).

Moreover, Marini (2008) insightfully attempts to extend this essentially correct *immanent* nexus between *economic content* and *political forms* of the capital relation to the sphere of uneven international relations, thereby rejecting those 'politicist' explanations of national differences based on 'diplomatic and military pressure by industrialised nations' (pp. 119–120). Unfortunately, in this latter endeavour, Marini's own attempt at a Marxian explanation of global uneven development is not entirely successful. In effect, when accounting for the specificity of capital accumulation in Latin America, Marini conceives of the latter as residing in a particular, *nationally embedded* method of production of surplus-value based on the 'super-exploitation' of labour, which, in turn, emerges as an 'adaptation mechanism' through which dependent economies react to the outflows of surplus-value that result from the 'unequal exchange' relations that they establish in international circulation with advanced capitalist countries (Marini 1978: 172–179, 2008: 124–127). In other words, for Marini the production of surplus-value is an attribute of each 'national total social capital', with its specificity determined by the *dominant* (i.e. essential but not necessarily exclusive) mechanism of exploitation of the working class. Latin American 'total social capitals' develop their own nationally based methods of production of surplus-value (super-exploitation) as a 'functionally determined' consequence of the methods originally developed in advanced countries (technical progress). In contrast, we shall argue in the next section that the production of surplus-value is an attribute of the *global total social capital*, whose *immanent unity or content* obtains at the level of the *world market*, but which becomes *self-differentiated* into qualitatively specific *national forms*. Thus, despite his valuable best efforts to ground the qualitative differentiation of the world market in the *economic* determinations of the unfolding of the 'law of value' on a *global* scale, even Marini ultimately *fails* to transcend the 'methodological nationalism' that characterises dependency theory as a whole.

In this sense, a common flaw of all versions of dependency theory lies in their conceptualisation of the essentially global unity of the process of capital accumulation. Specifically, in all cases, ranging from its different original formulations up to its contemporary revivals such as those in the Special Issue, dependency approaches ultimately explain the developmental course of each particular country in terms of the *interaction* between 'internal factors' and 'external constraints'. As we argue below, this approach cannot but represent the inner connection between global content and national form in its *apparent exteriority*. We shall come back to the general methodological limitation of this conception later on, when discussing the shortcomings of the U&CD approach. For the moment, let us examine its more concrete implications through a critical engagement with Ebenau's substantive argument on the limits to the recent 'centre-left' politico-economic experience in Argentina that started in 2003 and which has just come to an end in 2015 (a national instance of the broader so-called 'Pink Tide' that prevailed in many countries of the Southern Cone throughout that period).

According to Ebenau, this 'neo-developmentalist' project, which he identifies theoretically with the work of authors like Bresser-Pereira (2010) and Boschi and Gaitán (2009), and politically with the three 'Kirchnerist' administrations, clashed with two kinds of obstacle. The first one is the 'structurally problematic competitive position of Argentinian firms' in the context of the world market. As a result, these firms are unable to compete neither with China's (or even Brazil's) low wages nor with advanced countries' high productivity (Ebenau 2014: 109). In other words, and here Ebenau invokes a classic insight of dependency theory, it is quite simply impossible for all countries to attain 'autonomous development'. In effect, in the context of 'over-accumulation on a world scale […] the success of some producers will necessarily come at the cost of others, be they already established or aspiring competitors' (Ebenau 2014: 106). The successful progressive 'high road' to world market integration proposed by the neo-developmental political project is therefore highly improbable (if not quite simply impossible). In the second place, Ebenau also points to internal factors hindering autonomous national development. Fundamentally, Ebenau (2014) highlights the refusal of support to the strategy of 'industrial upgrading' by the domestic bourgeoisie (especially, the agrarian faction), who opted for a clear-cut strategy of 'dependent development' on the basis of a peripheral form of world market integration driven by the export of primary products (p. 110). Likewise, the project eventually failed to maintain the support of the workers' movement and other popular groups that it had enjoyed during its earlier years.

In our view, this empirical analysis replicates the more general theoretical shortcomings of the dependency approach mentioned above, and which derived from its conception of the world market as an externally related aggregate of national economies. Thus, it does not suffice simply to *empirically describe* the 'structural external constraints' confronted by recent centre-left administrations in Latin America to comprehend their limited potentialities for social transformation. This leaves us unarmed to *explain* the *qualitative* form of participation of these countries in the global process of accumulation, which *underpins* the *immanent* impotence to challenge and overcome those apparently external factors which are seen as hindering 'from outside' the national development project. To put it in more concrete terms, this account fails to explain, for instance, why wages in Argentina are not as low as in other 'peripheral regions' or the productivity of labour lags so far behind that of 'developed' countries. It just takes those phenomena as given empirical 'facts'. Similarly, it does not suffice to indicate the subjective 'preferences' of bourgeois factions, who for some unexplained reason are depicted as inclined towards profiting from 'commodity rents' (Ebenau 2014: 110) instead of supporting the state-led industrialisation project.[5] A proper 'critical-materialist' account needs to explain *why* the Argentine bourgeoisie adopted this 'accumulation strategy', which, in turn, should be grounded in the globally determined forms taken by the capital accumulation process in this particular national space of valorization.[6]

Finally, let us now examine the third alternative approach to the understanding of national differences in global capitalism put forward in the Special Issue (Hardy 2014; Taylor 2014). In contrast to the previous two cases, it does not draw inspiration from any variant of dependency theory but from Trotsky's analysis of U&CD. In its original formulation in the *History of the Russian Revolution* (Trotsky 2008), this perspective attempted to grasp capitalist development in 'backward' countries on the basis of the 'combination' of 'archaic' elements from domestic relations of production with those assimilated from more advanced capitalist countries. In Trotsky's view, this allowed 'backward' countries to skip 'a whole series of intermediate stages' in their attempt at catching up with advanced countries. Yet, Hardy (2014) notes that

> although Trotsky argued that an understanding of the 'whip of external necessity' has to be rooted in the inner workings of capitalism explained by Marx's law of value, he did not offer an explanation of the drivers or causes of unevenness. (p. 145)

To complete this explanation, Hardy (2014) thus points to capital's 'essential contradiction between a constant tendency for differentiation rooted in the division of labour and the organisation of production, and the opposite tendency towards universalisation reflected in the tendency towards the equalisation of the rate of profit'. However, this explanation of unevenness generated by each firm's aim at realising extra profit that leads to 'technological and institutional change as well as contestation by workers' (Hardy 2014: 146) is still rather abstract and falls short of explaining 'the division of labour [...] between countries'. In other words, as Hardy (2014: 146) remarks, 'this raises a key question regarding the theorisation of the relationship between national sate formations and the interdependence of the global market'.[7]

In order to address this further instance of U&CD, Hardy follows Barker's (2006) extended notion of 'combined development'. According to this view,

> 'national peculiarities [...] are a product of the world system as it is inflected within each separate state', so that 'each country is [...] shaped simultaneously by the development of social

> relations within its borders as well as by multiple forms of economic, political, military and cultural traffic across those same borders'. (Hardy, 2014: 148)

Thus, Hardy (2014) concludes 'the world economy and nation-states are not dichotomous entities', but are

> mutually constitutive in a process whereby nation-states are constrained and shaped by the parameters of accumulation processes in the global economy, but at the same time the strategies of states and capital reshape the accumulation processes in the global economy and forge a new set of parameters and dynamics. (pp. 148–149)

We find two main problems with the U&CD approach. In the first place, although it highlights the need to consider the 'world system' and the 'law of value' to understand national processes of accumulation, we think that the relations between them are ultimately represented in *external* terms. This is most evidently clear in Trotsky's 'classic' formulation, insofar as it conceives of national peculiarities on the basis of the 'combination' of given differences that had been generated by the universal law of unevenness and which *pre-exist* their articulation. Aware of this weakness, Hardy's reformulation proposes the inversion of the order between the 'uneven' and 'combined' aspects of capitalist development, that is, she relabels the theory as 'combined and uneven development'. However, in our view, this theoretical strategy does not suffice to eliminate the exteriority between the global and national dimensions of the unfolding of the law of value. In effect, we have seen that even in its revised version as C&UD, this approach still conceives of the relation between the global unity of the capital accumulation process and national differences as resulting from the *interaction* (or *mutual constitution*, in Hardy's words) of *elements* (i.e. 'world economy' and 'nation states'). And no matter how much two distinct elements influence, complement and transform each other through their interaction, they can only do so from an 'ontologically' prior and irreducibly self-contained existence. This point obviously has broader methodological underpinnings which exceed the scope of this article. But, as argued in great length elsewhere (Starosta 2015: 76–116), suffice it to note that this essentially 'Engelsian' view of dialectical relations as 'unity of opposites' still fails to capture the *movement of affirmation through self-negation* which constitutes the inner, immanent unity between the *content* and *form* of real phenomena. In contrast, we shall see below that the key question resides in explaining why and how the immanently global unity of capital accumulation (the content) becomes self-differentiated in national spaces of valorisation of qualitatively 'varied' kinds (the form), as it *subsumes* under its movement of formally boundless self-expansion the materially diverse determinations of different territories and human productive forces across the globe, thereby engendering historically changing constellations of the international division of labour.

This leads us to what we consider the second major weakness of the UC&D/CU&D approach to the study of 'peripheral societies'. In our view, and in a nutshell, this approach does not really constitute a theory proper but rather a *description* of the differentiated concrete forms taken by the establishment of the unity of capitalist development at the level of the world market (Rioux 2015). It thus still falls short of 'moving from *understanding to explanation*' as demanded by Coates in the passage cited above. In other words, it is self-evident that there is 'unevenness' in the world market (e.g. that there are more or less 'advanced'/'backward' or 'rich'/'poor' countries) and that there also is 'combination' (i.e. that each country assimilates 'elements' that had their origin in another national territory). The question is to account for the *reason to be or ground* of those particular 'differences and combinations', whose 'amalgam' determines national variation according to this approach. In this sense, the first task that a proper 'theory of capitalist differentiation' should undertake is the identification of which are the differences that actually matter for the emergence of qualitatively specific potentialities in the diverse concrete national forms taken by the global accumulation process.

According to our own alternative to the VoC approach based on the Marxian critique of political economy, the key to the comprehension of relevant forms of national differentiation resides in focusing on the historical dynamics of the *production of relative surplus value by the global total social capital on a planetary scale*. And this requires that we elucidate which territorially embedded qualitative differences acquire 'world-historical' significance from the point of view of their participation in the global process of relative surplus-value production. More concretely, we argue that the explanation of uneven development cannot take as point of departure already constituted national differences (whether institutional or class-based) in their apparently irreducible *singularity*, in order to thence proceed to their 'classification' as a national or regional 'variety of capitalism'. Instead, it must attempt to account for the *specificity* of each territorially or jurisdictionally demarcated space of valorisation, as it emerges out of the configuration of the capital-determined international division of labour. In the next section, we elaborate further on this approach and flesh out its implications for the study of the Latin American 'variety of capitalism'.

Uneven global capital accumulation and the role of Latin America in the international division of labour[8]

The historical specificity of capitalist production derives from the private and independent form taken by human labour. In this form of the human-life process, the social character of labour is represented as an objective attribute of its product, namely, the value-form, which determines useful objects as commodities (Marx 1976: 132). Social relations thus take the alienated form of powers of the product of labour, and human beings become determined as personifications of those objectified forms of social mediation; in its simplest form, as 'representatives of [...] commodities' (Marx 1976: 178–179).

This indirect form in which the unity of social labour is established is fully developed when it becomes capital. Subsumed under the capital-form, the production of surplus value – in short, the formally boundless quantitative progression of the reified 'social nexus' – becomes the content of social life (Marx 1976: 251–257). In this more concrete form as self-valorising value, the materialised social relation does not simply formally mediate the material life process of human beings, but actually becomes inverted into the very alienated subject of the process of social reproduction and its expansion *in its unity*:

the material metabolism of society takes the inverted form of the accumulation of the *total social capital* (Marx 1976: 763). In other words, in capitalist society the process of human metabolism is characterised by an automatism subject to laws, whose motion obviously takes shape through the conscious action of individuals, but whose general unity is unconsciously established 'behind theirs backs'. The 'law of value' is the succinct term that refers to the unity of the determinate forms of movement assumed by this alienated mode of existence of social life in all its concrete complexity.

In the process of renewal of the conditions for its self-valorisation, the total social capital produces and reproduces commodity owners as members of antagonistic social classes (Marx 1976: 723–724, 1978: 185). In its simplest determination, the class struggle is thus the most general *direct* social relation between collective personifications of commodities (thereby determined as a political form of social relations), which mediates the reproduction of the *indirect* relations of capitalist production through the generalised commodity form (thereby determined as the economic form of social relations; Iñigo Carrera 2013; Kicillof & Starosta 2007). Although a necessary form taken by the reproduction of the total social capital, the antagonistic character of the class relation disrupts the fluidity of the former's valorisation. The establishment of the general unity of social labour must therefore take shape through a further objectified form of social mediation, the state, which confronts commodity owners (the personifications of money-as-capital and of the commodity labour-power), as an apparently external power with the authority and capacity to establish the overall direct regulation of their antagonistic social relations (Iñigo Carrera 2012). The state thus develops as the most concrete political form that embodies the direct organisation of the unity of the conditions of social reproduction in its alienated capital-form. That is, the state is the concrete form of the essentially indirect social relations through the valorisation of capital. By virtue of this content, the state becomes the *general political representative of the total social capital*. In brief, capitalist social relations exist as differentiated into economic forms (the autonomised movement of capital-commodities on the market) and political forms (class struggle and the state). The latter, far from enjoying 'autonomy' (relative or otherwise), are the necessary mode of realisation of the contradictory content of the economic mode of existence of capitalist social relations. In other words, class struggle and state policies are not to be conceived of as independent, self-subsisting factors that externally modify or influence the workings of the law of value. Instead, they need to be grasped as necessary modes of motion through which the law of value further unfolds beyond the strictly economic forms immediately springing from the indirect nature of the social relations of capitalist production.

Now, as an expression of its inherently self-expansive nature, this fetishised social relation is global in content and national only in form (Clarke 2001; Iñigo Carrera 2013: 144–145; Marx 1973: 277–278). This means that it is the self-valorisation of value on a global scale, or global accumulation on the level of total social capital, that constitutes the immanent end in the world market (Smith 2006: 193). It follows from this that neither class antagonism nor its expression in the concrete form of state policies or 'domestic institutions' *determines* the modality and course of accumulation within each national space of valorisation. Instead, those nationally differentiated political and institutional forms mediate the unfolding of the underlying formal and material unity of the inherently contradictory dynamics of the accumulation of the total social capital at the global scale. Moreover, the immanent content of these global dynamics is not one of 'imperialism' or 'dependency' (i.e. a *direct political relation* between states, another mediating *form*), but determined by the production of (relative) surplus value on a world scale.[9]

This eminently unconscious and crisis-ridden social process gives rise to changing constellations of the international division of labour and, as a consequence, to evolving developmental potentialities for each national space that mediates the production of relative surplus value by the total social capital across the globe. The latter is, in sum, the general economic content that is realised in the political form of state policies (domestic and foreign) and class conflict, albeit 'behind the backs' of the antagonistic actions of the personifications involved (i.e. social classes and their diverse political organisations, political elites and/or state managers).

Now, as is recognised by virtually all accounts of the history of capitalist development in South America, and more broadly Latin America, the original subsumption of these territories to the global accumulation of capital was based on the production of agricultural (and/or mining) commodities for the world market (Furtado 1976; Marini 2008). As Marx (1976) remarks in *Capital*, the establishment of this 'classic' modality of the international division of labour was determined by the production of relative surplus through the system of machinery of large-scale industry (pp. 579–580). In effect, the exceptional natural conditions prevailing in many of these territories allowed for a greater productivity of agricultural or mining labour, thereby resulting in the cheapening of means of subsistence and a lower value of labour-power. However, this form of subsumption of Latin American territories into the global circuits of accumulation was ridden with a contradiction: if, on one hand, the total social capital enhanced its valorisation by reducing the value of labour-power, on the other hand, this was partly offset by the drain of surplus value, otherwise available for capital's appropriation, flowing into the pockets of domestic landowners in the form of ground-rent.[10] Moreover, to the extent that primary commodities produced in the region have been consumed overseas, ground-rent has constituted a continuous international *inflow* of social wealth.

Capital was thus driven to overcome this barrier to its accumulation capacity by reshaping those spaces of valorisation in order to recover part of that surplus value, through the establishment of an 'antagonistic association' with local landowners over the appropriation of ground-rent. From being simply a source of cheap raw materials and means of subsistence, those territories also became determined as sources of ground-rent recovery for global industrial capital. The developmental trajectory of these countries has been determined by the historical course of this modality of capital accumulation, not only throughout the so-called agro-export stage but also during the so-called import substituting industrialisation (ISI) phase and, in South America, until contemporary times (Iñigo Carrera, 2013: 145–158).

As Caligaris (2016) points out, insofar as 'the political representation of the global total social capital by the state is mediated by the national form taken by the accumulation process', the total social capital's recovery of ground-rent 'must take shape, first of all, in the appropriation of ground-rent by the national total social capital of "resource rich" countries through its own national state' (p. 66). This political mediation has been necessary in order to block the 'spontaneous' course of ground-rent towards landowners through a wide array of state policies that intervene in the circulation of ground rent–bearing commodities and divert its flow towards industrial capital.[11] Thus, the transfer of ground-rent has been achieved through different policy mechanisms (overvalued exchange rates, export and import taxes, direct state regulation of staple food and raw material prices, etc.), which resulted in the establishment of specific domestic conditions for the circulation of capital within those national territories.[12] Consequently, its appropriation could only be done by industrial capitals operating within those countries and whose circuit realised its final phase (i.e. the sale of commodities) almost exclusively on protected domestic markets of a very limited size vis-à-vis world market norms (Grinberg & Starosta 2009: 769ff). Although this has meant that individual capitals could not reach the scale needed for profitably utilising advanced technological conditions, they have compensated the resulting higher production costs with the appropriation of a portion of ground-rent. In this way, they have valorised at the average rate of profit despite their restricted magnitude and backward technologies. This abundant extraordinary mass of social wealth has systematically complemented the surplus-value extracted from the domestic working class to the point of marking the very specificity of the accumulation process in those national spaces.

The modality of the accumulation of capital based on the appropriation of ground-rent in Latin American–protected markets has been very attractive for domestic capitals which, with the exception of those producing ground rent–bearing commodities, were not competitive enough to sustain their expanded reproduction by producing for the world market. But additionally and fundamentally, those markets have proved especially profitable for industrial capitals of foreign origin (i.e. TNCs), which established there from the mid-to-late-1950s onwards. Unlike the internationalisation strategy of TNCs in East Asia (the establishment of 'world market' factories, whether directly or through original equipment manufacturer (OEM) arrangements), foreign capitals in Latin America operated with the smaller scale that those domestic markets required and, given their protected nature, actually made possible. In this way, TNCs in Latin America managed to valorise obsolete fixed capital and accumulate without spending a portion of surplus value in the active development of the productive forces of social labour. However, the other side of this same coin is that the scale of Latin American processes of capital accumulation continued to be structurally dependent on the highly cyclical evolution of the magnitude of ground-rent available for appropriation (hence the widespread 'political and institutional instability' characterising many Latin American countries).

This also explains the noticeable lack of dynamism of capital accumulation in the region since the mid-to-late-1970s, which was momentarily and only partially reverted during the recent 'primary commodities boom' that seems to be just coming to an end:[13] in effect, the mass of ground-rent, especially of agrarian origin, has been, on average, growing at a slower pace than its requirement by industrial capital in Latin American national spaces of accumulation. As a consequence, the process of capital accumulation in the Latin American countries slowed down or entered into deep crisis. In this context, and in order to compensate for the slowly growing ground-rent in sustaining industrial capital's profitability, these national processes of capital accumulation have resorted to other sources of extraordinary social wealth such as the payment of labour-power below its value and the massive inflow of global fictitious capital in the form of mounting foreign debts (the latter made available as a result of the expansion of international liquidity deriving from the long-standing crisis of global overproduction).

Now, since at least the late-1950s, the planetary production of relative surplus value by the total social capital has led to the emergence and gradual development and expansion of a novel configuration of the international division of labour, which has not simply displaced but co-exists alongside the 'classic' modality just sketched out. Premised on the concrete material forms taken by the further automation of the capitalist labour process and advances in means of transport and communication, the so-called NIDL has revolved around the *international fragmentation of the collective productive subjectivity of the working class* (Iñigo Carrera 2013: 66ff; Starosta 2016: 84–96). More specifically, the constitution of the NIDL has been the outcome of the transformation of the modes of existence of the global collective labourer brought about by the leap forward in the process of computerisation and robotisation of the production processes of *large-scale industry*, especially since the 'microelectronics revolution'.

Historically, the emergence of geographically dispersed 'chains of production of surplus-value' *started* with the relocation of simple manual labour processes while concentrating its increasingly more complex parts in advanced capitalist countries. This is the particular initial manifestation of the NIDL that Fröbel et al. (1980) rightly (though one-sidedly) captured in the late-1970s without being able to uncover its general content. Thus, the emergence of the NIDL has been originally guided by capital's search for not only relatively low wages but also domestic working classes whose specific productive attributes included the habituation to 'intensive, collective and disciplined labour' (Iñigo Carrera 2013: 66) under harsh conditions. However, as a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class. Each national sphere of accumulation that actively participates in the NIDL therefore tends to concentrate a certain type of labour-power of distinctive 'material and moral' productive attributes of a determinate complexity, which are spatially dispersed but collectively exploited by capital as a whole in the least costly possible manner. Note, additionally, that this point applies to intellectual labour as well. Insofar as the latter also becomes *relatively* simplified, the exploitation of the consequently less complex forms of intellectual labour-power can also be relocated to countries where capital finds those kinds of workers more cheaply and with a more compliant subjectivity, as the current literature on 'offshoring of innovation' and 'creative labour' illustrates (Ernst 2005; Huws 2014).[14]

Although this more recent global restructuring of the international of labour had its most emblematic expression in the 'late industrialisation' experience of East Asia since the 1960s (Grinberg 2016; Iñigo Carrera 2013: 66ff), it also had a profound impact in Latin America; paradigmatically in Mexico after the 'debt crisis' of the early-1980s and, more recently, in Central America and the Caribbean Basin.[15] Thus, despite the similar developmental trajectory of Mexico vis-à-vis Argentina and Brazil until the 1980s, in the past three decades the former country has transformed the specificity of its capital accumulation process. More concretely, it has become a source of relatively cheap and disciplined simple labour-power for industrial capital in general, which exploits it in the material conditions (of scale and technology) needed for competitive world market production (whether directly in Mexico through the *maquilas* regime, or mediatedly through the international migration of workers into the United States). Hence, the contrast with Argentina and Brazil, where capital continued to find it more profitable to valorise on the basis of the appropriation of a portion of ground-rent, because the specific kind of labour-power it needed either was not there or was not cheap enough, and/or because the mass of ground-rent was large enough to offset the benefits of a 'structural transformation' in the other direction by providing the source of extraordinary social wealth sustaining those profitable protected domestic markets.

In sum, we think that this approach can help overcome the limitations inherent in the 'methodological nationalism' of other perspectives by providing a basis for the study of VoC both across and within regions, which is grounded in the intrinsically *global* nature of capital accumulation. In the next section, we sketch out a brief illustration of the usefulness of this approach through the discussion of the recent trajectory of the automotive industry in Argentina.

Capital accumulation through ground-rent appropriation: the case of the Argentine automotive industry[16]

Throughout its six decades of existence since the installation of the first *manufacturing* plants in the mid-1950s, the Argentine automotive industry has been characterised by its small scale, the use of internationally backward technology and the relatively low productivity of labour. In effect, even after the so-called 'restructuring' of the 1990s, when a wave of investment gave way to a recovery and expansion of the industry that allowed it to overcome the prolonged crisis of the 1970s and 1980s, the scale and productivity gap with respect to 'world market' norms remained on the same levels as it had been in the 1960s. What is more, due to the high levels of local fragmentation of capital in contrast with the strong global tendency towards its centralisation, the gap actually widened when considered at the level of individual plants. Yet, despite these persisting features in the productive structure of the industry, the main automotive TNCs have not only maintained their direct manufacturing operations in the country but also have actually obtained equal or even higher rates of profits than those existing in the sector at the global level (Pinazo 2015; Sourrouille 1980). This obviously connects with our previous argument about the existence of a specific extraordinary source of valorisation of industrial capital in South America, which allows its normal reproduction despite its uncompetitive material conditions.

As a matter of fact, the prevailing approaches to this issue in the specialised literature resonate with the discussion of 'dependentista' perspectives in the second section of this article (Ebenau 2012; Weiss 2014). On one hand, the more widespread 'sociological' perspective has focused on the oligopolistic and/or speculative behaviour of TNCs, which would have allowed them – together with state policies – to focus their valorisation strategy on the imposition of abnormally high prices, thereby perpetuating the inefficiency of the sector (Jenkins 1984; Nofal 1989; Sourrouille 1980). On the other hand, more 'radical' views – and in particular those related to the *Marxist* strand of dependency theory – have placed greater emphasis on low domestic wages in relation to those in the more industrialised countries (Cimillo et al. 1973; Pinazo 2015). We think, however, that both analyses have focused only on the superficial manifestations of the valorisation of TNCs and have failed to identify the precise sources of social wealth which the latter appropriate *via* high prices and low wages.

Let us begin with the question of internal prices, which the vast majority of scholars tend to see as consistently higher than international ones, both before and after the 'restructuring' of the 1990s (Arza & López 2008; Jenkins 1984: 46; Llach et al. 1997; Sourrouille 1980: 81). Without disputing the veracity of this fact, it is often overlooked that throughout the history of the Argentine automotive industry, there has been sufficient solvent demand to validate domestic prices that were recurrently set above global prices of production. In other words, one must explain the sources of this exceptional purchasing power on the part of Argentine consumers relative to those of other countries. A first source of this higher solvent demand may be found in the specific market destination of automotive production. In effect, a part of the industry's output is absorbed as means of production and/or for the transport of agricultural commodities. And in order for agrarian capital to yield the normal rate of profit, the consequently greater costs incurred in the purchase of those dearer automotive means of production must be transferred 'upstream' towards the rent of the landowning class. Consequently, the social wealth that flows to TNCs via the sale of their product at commercial prices superior to those of production is, in the corresponding proportion, a part of the agrarian ground-rent whose appropriation determines the specificity of capital accumulation in Argentina. Furthermore, another share of the industry's output has been certainly destined for the luxury personal consumption of landowners. As is evident, the source of this purchasing power is also ground-rent.

But agrarian ground-rent also generated growing demand for automotive vehicles in general (and not only for those directly consumed by agrarian capital and landowners). It did so because one of the normal courses followed by agrarian ground-rent in Argentina has been its primary appropriation by the national state through the mechanisms mentioned in the previous section (e.g. high export and import taxes) and its subsequent conversion into public spending.[17] In this way, agrarian rent augmented the demand for industrial commodities in general, including of course that for the automotive industry. Consequently, the overpricing of vehicles destined for general domestic consumption (including some sectors of the working class) was also sustained, in the corresponding part, by agrarian ground-rent.

Thus, the existence of ground-rent was, directly or with the mediation of state policies, a source of growing demand for automotive vehicles. This explains the setting of domestic sale prices above international prices of production. Without this extraordinary source of social wealth that validated those relatively high prices, the fixing of protectionist measures – at the national or regional level – would simply have contracted the consumption of vehicles, instead of expanding it as happened in Argentina in every one of the expansive phases of the industry.

As mentioned above, the second main response offered in the literature to the question of the sources of the valorisation of automotive capital in Argentina is linked to the payment of internationally low wages. Usually, the 'advantage' derived from the hiring of cheap labour-power is interpreted simply as a reduction in costs (Barbero & Motta 2007; Santarcángelo & Perrone 2012), without identifying the reasons for the existing wage levels nor, furthermore, the source of the 'advantage' in question. Dependency theory, for its part, just asserts that this amounts to the 'over-exploitation' of labour-power; that is, that the *specific* source of profit in the 'periphery' lies in the 'abnormal' modality of extraction of surplus labour from workers (i.e. the sustained payment of labour-power below its value) *vis-à-vis* the forms of exploitation prevailing in 'advanced' countries (Cimillo et al. 1973: 55–56, 95–97; Pinazo 2015: 151–153; see also Marini 1979 for the Brazilian case). We think, however, that the question of the conditions of the purchase and exploitation of labour-power deserves a deeper analysis.

The crucial point in this regard is that the existence of lower wages does not necessarily involve a greater exploitation of labour-power. If we rule out the possibility that reduced wages could be attributable to a lower value of labour-power, which seems unlikely at least in Argentina, it must be noted that they could be explained either by a reduction in the number of use-values consumed by wage-workers or by the cheapening of 'wage-goods'. However, only the former case would be an instance of the purchase of labour-power below its value or, in 'dependentista' parlance, of 'over-exploitation'. In order to clarify which of these two possible situations has tended to prevail in Argentina, it is necessary to make a comparative analysis of both money-wages and consumption levels of Argentine automotive workers.

Now, there is no doubt that money-wages of Argentine autoworkers have been consistently lower than those prevailing in the United States, which could be taken as an indicator of *normal* wage levels for these relatively skilled workers at a global scale (i.e. those corresponding, on average, to the full value of this type of labour-power).[18] In effect, in monetary terms, the Argentine automotive wage has been less than a third of its US counterpart between 1960 and 2013 (at purchasing power parity exchange rates). This means that to put an automotive worker into production, TNCs must disburse as much as three times less variable capital than they would have to if they had to hire labour-power in the socially normal conditions of exploitation of labour-power prevailing at the global level. Nevertheless, the comparison of *real* wages shows that the Argentine automotive worker was capable of consuming almost two-thirds of the levels of consumption reached by a US worker. In other words, the Argentine worker's ability to consume was much closer to that of the American's than is indicated by the value of her or his wage. The explanation for this situation resides in the domestic prices of wage goods for the working class. In effect, within the Argentine space of capital accumulation, agrarian commodities circulate more cheaply than in the world market. Given that the domestic sale of these commodities below their normal price of production is only possible because of the existence of agrarian ground-rent, the cheapening of labour-power constitutes a vehicle for the appropriation of this rent by industrial capital and, in our case, by automotive capital. In brief, the process of appropriation of ground-rent by industrial capital explains to large extent the relative cheapness of labour-power in Argentina. Note, in this sense, that this cheapness does not derive from the 'historical and moral' element of the value of labour-power of national fragments of the global working class, which had formed a *latent relative surplus population* composed of formerly free peasants who were nonetheless subordinated to a centrally and hierarchically structured tributary system of exploitation (Iñigo Carrera 2013: 66), as happened in Korea and other East Asian countries (Grinberg 2016).

To conclude, the preceding analysis shows that the fundamental basis for the valorisation of industrial capital in Argentina has been the appropriation of a portion of the agrarian ground-rent that flowed into the country, both through the purchase of cheapened labour-power and through selling at prices that have been set above those of production. In this way, automotive TNCs have compensated for the backward technical conditions in which they have operated. In this context, other sources of extraordinary profits that did exist, such as the 'over-exploitation' of workers highlighted by Marxist 'dependentistas', acted as *secondary* or *complementary* forms of compensation for those backward material conditions of valorisation, rather than as the essential defining determination of the specific modality of accumulation of automotive capital in Argentina.

Conclusion

In a nutshell, our overview and appraisal of the various critical approaches presented in the Capital & Class Special Issue on 'capitalist diversity' allow to draw the conclusion that regardless of the undeniable theoretico-political differences among them, they nonetheless share a two-fold common ground. On one hand, they conceive of *political forms* (antagonistic class relations, the nation-state and public policies, international relations between states) as involving, to a lesser or greater extent, an element of autonomy with regard to the *economic content* of the accumulation of capital. On the other hand, and analogously, they tend to conceive of the configuration and developmental potentialities of *national* spaces of valorisation as involving at least some degree autonomy from the *global* dynamics of the 'law of value'.

In contrast, we think that to fully transcend the shortcomings of the neo-institutional VoC-CC literature rightly and accurately identified by the 'critical political economy' frameworks discussed above, it is necessary to leave behind the aforementioned two-fold notion of autonomy that implicitly or explicitly informs those perspectives. And this means taking the *immanent unity* of the capitalist world market as the starting point of the investigation and, as a consequence, grasping changing patterns of national or regional differentiation as concrete forms that mediate the unfolding of the contradictory dynamics of the essentially global production of relative surplus value by the total social capital. In turn, the specific political forms prevailing in each country are thus revealed as expressions of the movement of the economic forms taken by global capital accumulation in each national space of valorisation. In our view, these two insights are grounded in one of the most potent scientific discoveries of Marx's critique of political economy, namely, that capital is neither simply a thing (for example, the instruments of production) nor a productive unit or legal entity (such as a firm), or a social grouping sharing common characteristics and interests (e.g. 'business' or 'the bourgeoisie'). In its general determination as self-valorising value, capital becomes 'the all-dominating economic power of bourgeois society' (Marx 1973: 107), whose 'substratum' is the 'world market […] in which production is posited as a totality together with all of its moments' (p. 227).

Notes

1. See Schneider (2009) and Schneider and Soskice (2009) for an influential account of Latin America from the VoC perspective.
2. However, we believe that the implications of our discussion are more general and can be applied to other regions of the 'periphery' of the world market.
3. In particular, these issues have been examined with greater detail in an edited collection of essays which provides both an elaboration of the general theoretical underpinnings of this approach and various empirical 'case studies' at country and industry levels (Charnock & Starosta 2016).
4. For a comprehensive critical review of the Marxist literature on ground-rent, see Caligaris (2014). Although the issue of ground-rent has been widely discussed within Marxism, its connection with the specificity of capital accumulation in Latin America has not been as broadly addressed.
5. As a matter of fact, we think that it is actually misleading to depict 'Kirchnerism' as a political regime that incarnated the attempt to undertake a project of 'autonomous national development' that could have overcome the Argentina's 'dependent or peripheral' status, but which 'lamentably' clashed with both external structural limits and the insurmountable resistance of the local bourgeoisie on the domestic front. In our view, 'Kirchnerism' was the political and ideological form that, far from constituting the attempt to change the form taken by Argentina's 'integration into the world market', personified the expanded reproduction of this specific modality of the valorisation of capital throughout a prosperous phase based on an unprecedented upsurge of agrarian ground-rent, which was, in turn, the outcome of the course taken by the global process of accumulation. For a more detailed discussion of the nature and potentialities of 'Kirchnerism' and a comparative analysis with the Brazilian experience, see Grinberg and Starosta (2014).
6. We address some of the determinations involved in the third section of this article below.
7. Incidentally, in this more general analysis of the contradictory tendencies for uneven development inherent in capital accumulation, Hardy relies heavily on Neil Smith's (2008) 'dialectic of equalisation and differentiation'. Although based on an interesting and quite rigorous close reading of *Capital*, Smith's discussion remains at a rather abstract level of abstraction and so it is not very useful to make sense of the historically changing configurations of the international division of labour, as Hardy herself notes in the passage quoted above. In fact, in the occasional and usually brief remarks through which he does venture into more concrete territory, Smith (2008) tends to rely on long-standing Marxist ideas on the sources of uneven development (Amin, Emmanuel, Mandel) and only resignifies them in light of his dialectic of equalisation and differentiation (pp. 187–189, 290). For a critique of theories of unequal exchange based on the approach developed in this article, see Iñigo Carrera (2016a).
8. The first part of this section draws partly on Grinberg and Starosta (2014). Further elaboration of the arguments can be found in the essays collected in Charnock and Starosta (2016).
9. For a similar argument from a different perspective, see Burnham (1994) and Howe (1981).
10. Ground-rent is surplus-value potentially appropriated by landowners due to their differential and absolute *monopoly* over non-reproducible natural conditions of production that, respectively, increase labour productivity in the primary sector or allow production altogether (Iñigo Carrera 2007b: 11–14; Marx 1981: 779–823, 882–907).
11. As Caligaris (2016) also notes, the overt direct taxation of ground-rent has been virtually impossible to implement given its 'confiscatory' character. In effect, given the enormous mass of social wealth at stake, its direct taxation would involve the breach of the juridical principle of fiscal equity that governs capitalist private property (pp. 66–67).

12. See Iñigo Carrera (2007b) and Caligaris (2016) for a detailed account of those policies and their role in transferring ground-rent to industrial capital (and the former bibliographical source, in particular, for statistical evidence supporting this argument for the case of Argentina).
13. For the recent 'Pink Tide' in South America see, Grinberg and Starosta (2014) for Argentina and Brazil and Purcell (2016), for Ecuador and Venezuela.
14. Ireland's software industry is a case in point (Friedenthal & Starosta, 2016).
15. Likewise, the NIDL has underpinned the recent contradictory dynamics of the accumulation process in the European 'periphery', as attested by the case of Spain (Charnock et al. 2014, 2016).
16. This section summarises arguments more fully developed in Fitzsimons and Guevara (2016), which also provides more details on data, sources and methodology.
17. From 1960 to 2007, the Argentine State annually appropriated, on average, 20% of the total ground-rent that flowed out of agrarian production, with peaks of 50% in some periods (see Iñigo Carrera, 2008).
18. Note also that skill requirements of direct production workers in Argentina have been relatively similar to those in 'advanced' countries such as the United States.

Marx and Socially Necessary Labor Time. On the Content and Form of the Quantitative Determination of Value

Gastón Caligaris[1], **Alejandro Fitzsimons**[1], **and Guido Starosta**[1]

Abstract
This article revisits the debates on socially necessary labor-time (SNLT) in the light of contemporary discussions of Marx´s value-theory, which have tended to move from a rather narrow focus on the explanation of the economic basis of the exploitation of wage-workers, to a wider critical inquiry into the social constitution of alienated forms of mediation that structure capitalist society. Moreover, this re-examination of SNLT draws on a novel reading of the textual evidence offered by the critical edition of the manuscripts for Capital, against the backdrop of a brief overview of the controversies between the three main interpretations which can be found in the literature, and the development of an alternative systematic-dialectical presentation of the constitution of the content and concrete forms of realization of the quantitative determination of value.

Keywords
socially necessary labor time, market value, solvent demand, Marxist debate, value theory

Introduction

The last couple of decades have witnessed a remarkable shift in the main themes and preoccupations prevailing in debates surrounding Marx's economic works. Broadly speaking, it could be argued that the discussion moved from a rather narrow focus on the explanation of the economic basis of the exploitation of wage-workers to a wider critical inquiry into the social constitution of alienated and reified forms of mediation that structure the capitalist organization of social life (e.g., Bonefeld 2014; Heinrich 2021; Iñigo Carrera 2021; Kurz 2016; Postone 1993). The angle of specialist contributions specifically addressing the fundamental issues in Marxian value theory has changed accordingly. Thus, whereas in the past the main concern had been the formally consistent demonstration of the reduction of prices to quantities of labor, contemporary scholars tend to gear their intellectual efforts to the explanation of *why*, in capitalist society, labor takes the *social form* of value. In turn, this renewal of debates has been grounded in a philological re-reading of Marx's works, which has been largely motivated and facilitated by the publication of the respective section of his original manuscripts for *Capital* undertaken by the editorial project known as MEGA^2 (see, for instance, Bellofiore and Fineschi 2009).

Now, these new readings of Marx´s economic works have sought to rethink a wide array of problematics pertaining to the determination of economic categories as fetishized social forms, such as the respective roles of production and exchange in the constitution of value, the materiality and social form of abstract labor, the money-form as the necessary mode of expression of value, among others. Yet, while this new spate of Marxist approaches has greatly contributed to throwing into relief those varied aspects of the qualitative determination of value as a materialized social relation, it seems to us that those novel insights and perspectives have not been similarly extended into an equally in-depth re-examination of the quantitative determination of value (for notable exceptions to this trend see, e.g., Moseley 2023a; Iñigo Carrera 2021). More concretely, we think that the meaning of the key notion of *socially necessary labor time* (SNLT) which, according to Marx, underpins the magnitude of value, has not been sufficiently rethought, or at least not in a systematic categorial fashion, in the light of these new approaches to the Marxian critique of political economy. As we shall see, the elucidation of this issue is not only crucial for a sound comprehension of both the content and concrete forms of the value-determinations in their unity; in addition, it has not been exempted from controversies in the Marxist literature since the publication of *Capital*.

Against this backdrop, the aim of this article is to revisit the debates on SNLT in the light of contemporary discussions of Marx´s value-theory and with recourse to the textual evidence offered by the critical edition of the manuscripts for *Capital*. To do so, the article is structured as follows. The first section offers a brief overview of the controversies which traces the three main interpretations which can be found in the literature. Subsequently, we present our own approach to the constitution of the *content* and *concrete forms of realization* of the quantitative determination of value based on Marx's systematic-dialectical exposition in *Capital*. Lastly, the third section examines the main passages from Marx's economic works whose diverging interpretations have underpinned the different theoretical positions under debate. Furthermore, it provides an alternative reading of those controversial pieces of textual evidence.

It goes without saying that the philological discussion should not be read as an end in itself. It is just a way of putting our main substantive argument across against the backdrop of the historical and contemporary academic debates around this issue, which have tended to take such a philological angle on the question. In a nutshell, we shall see that the fundamental issue at stake is the connection between production and circulation in the historically specific social form of the human life-process in capitalism.

Brief Historical Overview of the Debate on SNLT

The discussion over the meaning of SNLT can be traced back to just after the publication of the first volume of *Capital*. As Grigorovici reports, the first wave of reactions to this work tended to assume that when Marx spoke in the preface of "important mistakes" in Lasalle´s understanding of his theory, he had SNLT in mind (Marx 1976, 89 fn.; Grigorovici 1910, 4). More precisely, this initial reception of *Capital* understood that Lasalle would have misinterpreted Marx by imputing him the idea that SNLT refers to that which society is willing to validate on the market, whereas it is crystal clear that at stake in the determination of the magnitude of value was the labor-time required for the production a commodity. However, Grigorovici also notes that already at that time some Marxist contributions tried to reconcile both understandings of SNLT (Grigorovici 1910, 18). The publication of *Capital Vol. III* and of *Theories of Surplus Value* reignited the controversy. In effect, these works contained some passages which seemed to allow Lasalle´s allegedly market-centered reading or, at least, a middle ground which reconciled the latter with the traditional "production-centered" understanding of SNLT. In this emerging new context, Marxist approaches to SNLT polarized into those authors who sought to develop further the interpretation of this economic phenomenon as determined by market conditions, and those who wanted to preserve a reading which grasps it as exclusively determined by the conditions of production.[1]

---

[1] According to Rubin, an analogous debate came up among Russian Marxists in the 1920s (Rubin 1972, 185 fn.; see also Groll 1980, 338 fn.; and Swanson 1989, 61). Similarly, Itoh and Yokokawa comment that the same happened among Japanese Marxists a few years later (Itoh and Yokokawa 2015).

Concerning the former, those early contributions quite simply adopted the suggestion, which many tended to assume originated in Lasalle´s reading, that effective solvent demand on the market determined SNLT and, consequently, the magnitude of value of commodities (Bernstein 1899, 1993, 51; Boudin 1920, 68–70). The quantitative divergence between prices and values, which recurs in Marx´s text, was seen to boil down to express the singularity of each act of exchange among all those simultaneously taking place on the market, based on the respective "haggling" abilities and individual motives and subjective estimates of exchangers (Boudin 1920, 66–67). As for the determination of value by the labor-time required to produce each commodity (without regard to effective demand), this was ultimately reduced to a merely *subjective* logical instance, which would effectively play no actual role in the explanation of the *objective* constitution of its immediate mode of existence as price (whether market price or price of production) (Bernstein 1993, 47–48). Among contemporary Marxists, this is the kind of interpretation which, arguably, would be consistent with so-called "value-form" approaches that explain the qualitative and quantitative social constitution of value through the exchange of commodities and money (as inferred, for instance, in the literature review offered by Kristjanson-Gural, 2017). Yet, it is not easy to find among those contributions an *explicit* philologically informed discussion of the question of SNLT in the systematic architecture of *Capital* (see, however, Fineschi 2001, 269 ff.; and Tombazos 2013, 34–56, for a more extended discussion of SNLT which is broadly sympathetic to the main tenets of the so-called "value-form" approach).

At the opposite end of the spectrum, other Marxists entirely rejected the role of demand in the determination of SNLT and insisted that the latter exclusively referred to the conditions of production of commodities. For its part, the imbalance between demand and supply was seen as only affecting the divergence between prices and values. If anything, effective demand could trigger a *change* in the normal conditions of production and, *therefore*, a modification of SNLT and the value of commodities. Arguably, this perspective eventually consolidated as the dominant view among Marxists (cf. Meek 1973, 178–80). However, it is noteworthy that very rarely have scholars who endorsed it self-consciously placed their own views in the context of a longstanding controversy or sought to situate their views in the light of the textual evidence from Marx´s writings. Be that as it may, among this latter group we can include the contributions by Grigorovici (1910, 30 ff.), Rosenberg (1979, 383 ff.), and Salama (1978, 219 ff.). In more recent times, the approach resurfaced in the works by Lianos and Droucopoulos (1992), Cipolla (2003; 2008), and Moseley (2023b).

As we shall explore in more detail in the last section, the textual evidence from Marx´s economic works is, at least at first sight, not free from ambiguities, and therefore is very far from unequivocally offering support for either of the two "extreme" positions in the controversy. For that reason, most contemporary Marxists have veered toward what could be labeled as an "intermediate" position, in which both the technical conditions of production and the volume of effective demand determine SNLT and, consequently, the value of commodities. More concretely, it is usually argued that the (conjunctural) level of effective demand establishes the specific technical condition that regulates SNLT, out of the different labor productivities prevailing in a certain sphere of production. Thus, either the "inferior," "mean," or "superior" conditions of production could be validated by effective demand as that which determines the value of commodities. Furthermore, these contributions tend to see the emergence of a divergence between price and value only when the intensity/weakness of demand makes market prices rise/fall even further *beyond* the individual value of any of the two extreme conditions of production. Although this kind of reading can be traced back to the writings of Rubin (1972, 173–222),[2] it gained prominence mainly through Rosdolsky's contribution (1977, 88 ff.) and also via the dissemination of Uno's approach (1977, 83), especially as propagated by his disciples and followers (Itoh and Yokokawa 2015; Itoh 1980, 80 ff., Itoh 1988, 226 ff.; Sekine 1982, 1997, 33, Sekine 2020, 547 ff.). Still, a reading along those lines has been accepted quite widely among many Marxists, not necessarily inscribed in those intellectual lineages (cf. Vygodsky 1967, 89 ff., Vygodsky 1974, 83 ff.; Indart 1987, 1990; Horverak 1988; Swanson 1989; Shaikh 1990; Carchedi 1991, 57 ff.; Martínez González 1993, 64 ff.; Giussani 1996; Lee 1998; Mariña-Flores 1998; Kristjanson-Gural 2003, 2017; Balardini 2017, among others).

Now, although this latter reading admittedly manages to give some formal coherence and unity to the textual evidence which forms the focus of the controversy, especially to that which is found in Volume III of *Capital*, we think that it nevertheless fails to offer a solid approach to the content and form of the value-determinations which is rigorously grounded in the methodological and substantive foundations of the Marxian critique of political economy. Above all, insofar as the magnitude of value is seen as possibly determined by one of the extreme conditions of production, the total socially necessary abstract labor expended in a determinate branch of production no longer coincides with the total mass of value allegedly produced in the said sphere of the social division of labor. That mass of value thereby ceases to be the reified social representation of the materiality of the aliquot part of social labor that has been objectively expended in that sphere of production. More generally, that reading fails to avoid the essential weakness that could be imputed to any view which, whether wholly or in part, assigns a role to effective demand in the determination of SNLT and the magnitude of value of commodities, namely: insofar as it somehow cuts off the immanent nexus between the actual expenditure of living labor and the constitution of the objectivity of value, it ends up tearing asunder the contradictory unity between materiality and social form which is historically specific to capitalist society (Iñigo Carrera 2021; Starosta, Caligaris, and Fitzsimons 2023, chapters 1 and 2).

---

[2] Rubin´s emphatic insistence that his approach stands in stark opposition to that which postulates that (market) value is determined by effective demand (Rubin 1972, 182–84; 197–99; 206), has led commentators to place him among those who reject the idea that the latter plays a role in the determination of value (e.g., Kristjanson-Gural, 2017). However, we think that, on closer inspection, Rubin´s argument is much more nuanced and comes rather close to what we have just called "intermediate" position (Rubin 1972, chapter 17 in particular).

The Quantitative Determination of the Magnitude of Value by SNLT and its Form of Manifestation in Circulation

In addition to the controversy over the interpretation of passages in which Marx seems to link SNLT to conjunctural market conditions[3], the Marxist debate also revolved around whether the meaning of SNLT changed with the passage from the simpler level of abstraction of the commodity-form to its more developed mode of realization through the competition among multiple individual capitals that mediates the unity of the global process of capitalist production. For this reason, in order critically to examine the Marxian texts which ignited the polemic (most of which correspond to the level of abstraction of capitalist competition), in this section, we firstly offer a methodologically informed systematic exposition of the unity of the content and the different more concrete forms taken by the quantitative determination of SNLT and the magnitude of value.

Now, any investigation of the quantitative determination of a certain phenomenon must start out by shedding light on the essential quality of the attribute or property whose magnitude we seek to analyze. Space restrictions do not allow us to engage in an in-depth examination of this issue, a task that we have undertaken elsewhere through a discussion of contemporary Marxist debates on the qualitative determination of value (Starosta, forthcoming; Starosta et al., 2023). Still, here we would like briefly to address at least the essential questions at stake in those latter controversies which, we think, underpin the debate over SNLT that constitutes the main focus of this article. More specifically, the fundamental issue is whether the social constitution of value, as the historically specific social form of the product of labor, takes place in production, in circulation, or in some kind of unity between both spheres. Under the influence of the writings of Rubin (1972), a great deal of contemporary Marxists have rejected the old "technological" or "asocial" readings which had dominated until the 1970s through the adoption of some variant of the so-called "circulationist" perspective, whether in the "extreme" version which more one-sidedly grasps value as coming into being in circulation (cf. Heinrich 2021; Reuten 1988), or in the more nuanced "co-constitutive" views which are at pains to give the sphere of production its due place in the constitution of value as a social form, but which still consider that it is only through the eventual effective exchange against money that value acquires full objective existence (cf. Bellofiore 2018; Murray 2016). There is no doubt that these new readings manage to remain safe from the naturalization of value which was more or less implicit in the old orthodoxy, which simply rested content with its analytical reduction to labor as its source, but never openly addressed the question of the historically specific social constitution of value as a fetishistic social form. However, by lapsing into "circulationist" arguments, these more recent approaches avoid a Ricardian account of the value-objectivity at the expense of depriving the immediate process of production of its immanent social character (Iñigo Carrera 2021; Starosta, Caligaris, and Fitzsimons 2023).

---

[3] This section partly draws on Starosta, Caligaris and Fitzsimons (2023, chapter 2).

More specifically, all variants of "circulationist" value-form theory fail properly to come to grips with this essential fact: the private and independent form taken by the organization and establishment of the unity of social labor, which marks the specificity of value-producing labor, does not *do away with* or *abstractly negate* the social determination of individual *living* labor *in act or in motion*, that is, *as it exists in the direct process of production*. What happens in a commodity-producing society is that this *materially immanent* general social character of individual labors is not carried as a *conscious determination* by the working subject. Consequently, when organizing the expenditure of the labor-power that they embody, the human individual must unconsciously project or transpose those individually borne social powers as external to their individuality and existing as the objective attribute of the product: the social property of exchangeability or value (Marx 1976, 166–67).

In sum, the key to understanding value as *both* social and grounded in production resides in the recognition that at stake in value-positing is the "unconscious" organization of the determination of privately-undertaken labors as successfully integral individual organs of social labor; a fact which, albeit not "guaranteed," becomes established or not in the sphere of production. What remains to be established in circulation, upon completion of a privately undertaken production process, is not the *positing* or *constitution* of its social determinations (i.e., their coming into objective existence), but their explicit outer *expression* and *accreditation* in a socially recognizable and generally valid manner. The exchange relation performs this necessary yet *mediating* role, through the inverted outward expression of the inner social property of exchangeability intrinsic to each individual *socially useful* product of private labor, as the immediate social power of the general equivalent (Iñigo Carrera 2021). Let us consider the quantitative determination of value in this light.

In chapter 1 of *Capital,* Marx discusses the magnitude of value solely as a corollary of an investigation whose guiding thread lies in its qualitative determination. Consequently, his discussion does not go beyond a formal-analytical indication of the inner content of value's quantitative determination and the elucidation of the necessity of its outward form of manifestation in the body of the equivalent. Specifically, Marx's initial analysis of the exchange relation shows that value abstracts from all qualitative differences, so that its substance must also be qualitatively homogeneous. However, the analysis of the magnitude of the substance of value confronts us with two qualitative differences, namely: the productivity and intensity of labor. In this context, Marx simply makes the formal observation that the qualitatively undifferentiated character of the substance of value implies that the singularity of each productive action, which involves individual material differences in the aforementioned two features of labor, must thereby socially count as identical to any other individual expenditure of human labor-power, that is, as an aliquot part of the total labor-power of society or as an "average sample of its kind" (Marx 1976, 130).

This is all that Marx says, and actually all that could be said from the viewpoint of the systematic-dialectical exposition, concerning the quantitative determination of value; at least until chapter 3. In effect, as argued elsewhere, the analysis can just uncover the "what" of a determinate phenomenon. But only the synthetic development of the unity between the discovered content and its concrete forms of existence can account for the "why" and the "how" (Starosta 2008). Nevertheless, one could wonder whether the discovery of private labor which marks the specificity of the capitalist organization of social labor could cast additional light on the ground of the magnitude of value. More concretely, the question is how can the social recognition of the quantity of necessary labor be established in a society with no directly collective power which could determine the productivity and intensity with which to exert the labor-power possessed by the different individuals? In these circumstances, the only way the normal conditions of production can assert themselves is through the constitution of an average out of the multiplicity of diverse independent singularities, which tend to converge towards the said normality (Iñigo Carrera 2021, 49).

Two additional issues must be thrown into relief. First, no matter how concise Marx's discussion of the magnitude of value in chapter 1 of *Capital* is, the point remains that the *content* of the quantitative value-determination has been fully unearthed by that stage. In this sense, nothing in the subsequent systematic exposition can alter that initial potentiality of the commodity. The only thing that could change and be brought more fully into view is its necessary *form of realization*. Second, Marx's presentation in chapter 1 already shows that for the product of labor to be bearer of value, it must be a *social use-value*, that is, it must satisfy the need of a different individual from its producer (Marx 1976, 131). From the standpoint of *commodity-producing labor*, this means that it must be *useful for others*. That is why one could legitimately refer to a second sense in which commodity-producing labor must be "socially necessary." However, this has absolutely nothing to do with the determination of the magnitude of the commodity's value. Yet, circulationist readings conflate these two clearly different meanings to assign "effective demand" a role in the quantitative determination of value. But the "effective demand" is a phenomenon of circulation, which we have already seen has no place in the *constitution* of value as social form. In fact, at this initial "level of abstraction" the dialectical presentation has not even led to face such thing as "demand," so it could hardly enter as an element of the simplest content of value. At stake in chapter 1 is only the *expression* of value, and therefore the *constitution of the price-form as such*. "Demand" has the latter as its systematic premise; it concerns the concrete form of realization of the price-form in the effective practical movement of the circulation of commodities.

In this sense, it is crucial to distinguish among the different systematic steps in the constitution, ideal expression, and effective realization of the determinations of value. To do this, in the 1859 *Critique* Marx differentiates between what he calls the "theoretical phase of circulation of commodities" and the actual circulation process. The theoretical phase of circulation of commodities is then deemed "preparatory to real circulation" (Marx 1987, 303), since the latter can only take place once, "as a result of the establishing of prices, commodities have acquired the form in which they are able to enter circulation" (Marx 1987, 323). Only then (section 2 of chapter 3 of *Capital*) is the actual movement of circulation of commodities reproduced in thought, revealing the subsequent functions of money not as its preconditions (presupposed more abstract forms) but as its results (its developed concrete forms). By that point, the question no longer resides in elucidating the "what" of the quantitative norm that constitutes the magnitude of value, but rather in shedding further light, albeit preliminarily and incompletely, on the "why" and, primordially, on the "how."

As Marx stresses on the section on the "Measure of Value," although the "price or money form" of commodities is a "purely ideal or notional form" in which value is *expressed*, the latter is nonetheless *determined* by the (socially necessary) "quantity of human labor" *materially* contained in (socially useful) products as they emerge from production (Marx 1976, 189–190). Thus, the *unity between the immanent qualitative and quantitative determinations of value*, which constitutes the *objective* inner content that is *outwardly* expressed in the monetary form of the "normal price" of a commodity, must evidently be the *systematic premise* of the formal possibility of, and actual necessity for, a "quantitative incongruity between price and the magnitude of value" *in circulation* (Marx 1976, 196). In other words, from a systematic-dialectical perspective, already-determined *normal prices* (both qualitatively and quantitatively) must constitute the explanatory presupposition of market prices that deviate from them by virtue of a disequilibrium between "supply and demand" manifested in circulation (cf. Marx 2015, 298).

As matter of fact, this methodological angle underpins Marx's "thought experiment" in chapter 3, through which he eventually follows the movement of the *effective* circulation of commodities. A certain number of pieces of linen arrive at the market *with their value already and solely determined* by the "materialization of the same socially determined quantity of homogeneous human labor" contained in each of them, which are in turn monetarily expressed in a "normal price" of 2 shillings (Marx 1976, 202). On that basis, Marx *then* supposes that the "market cannot stomach the whole quantity" of articles at that normal price, which *implicitly* leads, through the competition process among weavers, to a fall in the market price of the yard of linen below the magnitude of value.

Marx then closes his thought experiment with the observation that, from that moment on, he shall consider the phenomenon "in its pure shape" (Marx 1976, 203). This involves abstracting from the "abnormal loss or accretion of substance" of value which may result from the "change of form" of the commodity, if the latter "is not impossible to sell" (Marx 1976, 203).[4] Marx thus leaves the matter at that and proceeds with the further unfolding of the individual commodity's metamorphosis. However, there are a couple of additional points which could be made in this regard.

First, it must be stressed that it is not that the commodity loses/gains magnitude of value, but that its change of form *entails*, respectively, a loss or accretion of value for the seller or buyer of that commodity. What one abnormally loses is what the other gains and vice versa (Iñigo Carrera 2021, 278–81). Second, and beyond Marx's explicit focus, when circulation is grasped from the standpoint of the overall unity of social production and consumption, an additional quantitative meaning of "socially necessary labor" comes to the fore (Marx 1989a, 132). Briefly stated, there emerges another "quantitative norm" in the articulation of the general social division of labor, namely: the proportional allocation of the total social labor into the different branches of production. This reveals that the establishment of the unity between social production and consumption entails a definite magnitude of what becomes determined as the *normal social need* for each kind of use-value. At this level of abstraction, this corresponds to what is required for the reproduction of the productive attributes of commodity-producers. Furthermore, this brings to view the organic character of each individual commodity as an aliquot part of the quantitatively determined normal mass of commodities of a qualitatively certain type. From the standpoint of commodity-producing labor, this shows that the quantitative determination of value-production is not a process which simply concerns each "isolated" commodity but pertains to the organic (sub)unity of each branch of social labor (Marx 1976, 202; 2015, 302). Still, although this quantitative determination of the normal social need is *discovered* through the examination of circulation, it is an *immanent material determination of the organization and execution of direct production*. As elaborated in more detail elsewhere, production is the point of the departure and ground of the unity of the process of metabolism and, therefore, also of social consumption (Starosta, Caligaris, and Fitzsimons 2023).

Now, a partial overproduction of a certain kind of use-value *vis-à-vis* the normal social need does not imply that there has been no value production corresponding to that excess "supply." Instead, it means that too much value has been produced compared to the normal scale in that sphere; or, as Marx puts it, that "all these pieces taken as a whole [...] contain superfluously expended labor-time" (Marx 1976, 202). Thus, this value does not just simply vanish into thin air but is appropriated in another node of the social division of labor. In effect, the very existence of a normal inter-branch proportional distribution of social labor implies that the excess in value-production in one node must involve a correspondingly insufficient scale of value-production in another. The competition-driven divergence of market prices from normal prices that directly express the immanent magnitude of value "constantly regulates this distribution" of "necessary labor time [...] among the various spheres of production" (Marx 1989a, 132). Under these circumstances, and from the viewpoint of the unity of social production and consumption, *all privately undertaken material expenditure of SNLT proves to have been socially useful in a qualitative sense*. In terms of its "purely social" representation as the "exchangeability" of its product, the total mass of value materially borne by all *socially useful* products of private labor is realized in circulation, although it is (partly) appropriated in different spheres from those in which it had been produced (Iñigo Carrera 2021, 278–81). In sum, the imbalance between "supply and demand" is but the self-negating form in which the proportional distribution of social labor-time is established when mediated by generalized commodity-production.

---

[4] Were the product of private labor quite simply "impossible to sell," it would mean that it was not a social use-value nor, therefore, bearer of value, from the very outset in production.

At this juncture, a final methodological observation is in order. Note that Marx's analysis in chapter 3 stops short at the indication of a necessity for a quantitative divergence between market prices and normal prices and does not unfold the adjustment mechanism which tends to eliminate the underlying imbalance between production and social need for the respective use-value. Presumably following his own methodological remark in the 1859 *Contribution* that the "coming into being" of a "market price differing from exchange value" must be "solved in the theory of competition" (Marx 1987, 302), that mediating process is not fleshed out until Volume III, once Marx has already developed the exchange of commodities as the product of individual capitals determined as formally undifferentiated aliquot parts of the total social capital, that is, through the formation of the general rate of profit. In effect, the competition over the appropriation of the general rate of profit is the concrete form in which the requirements for the normal material reproduction of society are imposed upon capitalistic private producers (i.e., individual capitals). This applies both to the SNLT required to produce each commodity and to that which is needed for the total mass of commodities in the respective sphere of production.

At this more concrete level of the dialectical exposition, Marx analytically distinguishes between intra-branch competition, which mediates the realization of the value of commodities, and inter-branch competition, through which prices of production come about. That latter presupposes the distinction between values and market prices (Marx 2015, 304). Regarding intra-branch competition, Marx distinguishes between an "individual value," which represents the privately-undertaken individual labor-time embodied in a commodity, and a "social value," as the representation of the latter which is determined as socially necessary insofar as it expresses the normal conditions of productivity and intensity of labor prevailing in a certain branch of industry (which, as we have argued above, are exclusively established in the sphere of production).[5] In turn, insofar as the point is to mediate the actualization of the social value through competition, it is necessary to distinguish between a market price, which is the immediately visible mode of existence of value, and a *direct normal price*, as the *simplest* monetary expression of the social value, which is the gravitational center around which the former fluctuates. We refer to the latter form of manifestation of the social value as "direct" insofar as it involves no quantitative divergence from its immanent magnitude.[6]

Now, commodities reach the market as the result of diverse conditions of production. Consequently, their normal price will reflect the average of their respective individual values. Hence, if commodities produced under mean conditions have the greater weight, whilst those in the respective ends of the spectrum cancel each other out, the normal price will be "regulated" by the former (in the simple *arithmetic* sense of proportion in the weighted average). By contrast, if any of the extreme conditions predominates, they will have the "upper hand" in the constitution of the normal price. As Marx observes, individual capitals will consequently gain/lose value to the extent that the individual value of its commodities stands below/above the resulting normal price (Marx 2015, 289).[7] Through these divergences the norm that constitutes SNLT is imposed upon individual capitals.

Once the formation of the normal price has been elucidated, it remains to be considered the mode in which the former takes concrete shape through market prices. Another quantitative difference emerges, but now concerning the normal conditions for the unity between social production and consumption. In other words, at stake here is the relation between the total social labor that has been privately expended in the production of a certain kind of use-value, and the normal magnitude of the (solvent) social need which is meant to satisfy. An imbalance will be expressed through a divergence between the respective market price and the normal price which constitutes the simplest monetary expression of the social value (Marx 2015, 291; 297–304). Thus, this divergence between an already-constituted normal price and market prices, which will also be expressed in the individual capital's capacity to obtain the average rate of profit, will be the mode in which the *normal* magnitude of social labor which must be allocated to a certain branch of production, will be imposed upon individual capitals.

---

[5] In *Capital*, Marx explicitly introduces for the first time such a distinction in chapter 12 of Volume I (Marx 1976, 433; see Starosta, Caligaris, and Fitzsimons 2023, chapter 6). However, it thereafter fades into the background until the exposition returns to the more systematic treatment of competition in chapter 10 of Volume III.

[6] As we shall discuss in the next section, Marx includes this direct normal price in the definition of what he calls "market value." However, his usage of this latter term is broader and incorporates other phenomena.

[7] This process only involves normal capitals, that is, those which partake in the active development of the productive forces by virtue of their scale, in contrast to "small capitals." See Iñigo Carrera (2016) and Starosta, Caligaris, and Fitzsimons (2023, chapter 8) for a fuller discussion of the qualitative differentiation of individual capitals.

The Discussion Around the Textual Evidence

Let us now turn our attention to the passages of *Capital Vol. III* and *Theories of Surplus Value* which have been at the center of the controversy on SNLT. Among them, there are a couple which stand out for Marx´s comment that SNLT "acquires another meaning," insofar as it can be considered as "[t]he total quantity of labor time used in a particular branch of production" vis-à-vis "the total available social labor" (Marx 1989a, 131–32); that is, "that only the necessary part of the total labor time of society is used in the particular sphere, only the labor time which is required for the satisfaction of social need (DEMAND)" (Marx 1989b, 150). Elsewhere, Marx refers to this other meaning of SNLT as "a further developed expression of the law of value in general" (Marx 1991a, 774).

Furthermore, there are other instances in which Marx seems to be stating that a disequilibrium between supply and demand plays at least some part in the determination of what at those junctures he calls "market value" (Marx 1991a, 284, 286–287). This strikes us as rather problematic insofar as there are passages in which Marx appears to identify this latter term with what he had named "social value" in Volume I; which, as argued in the previous section, is determined solely in production as the representation of socially normal material conditions of productivity and intensity of labor. Yet, to complexify things further, we shall also see that in other parts of his manuscripts Marx seems to use the term "market value" more broadly. Thus, there is an admittedly striking lack of categorical clarity and precision in the nexus between the term "market value" introduced in Volume III, and that of "social value" from Volume I. Presumably, this paved the way for readings which, one way or another, end up maintaining that market disequilibria affect the determination of value as such.

Against this backdrop, we would like to offer an alternative reading of the textual evidence at play in the debate. First and foremost, we should point out that the connection between the "second sense" of SNLT and the definition of market value is textually very weak. On the one hand, most passages in which Marx refers to this other meaning of SNLT are not located in the parts of his manuscripts where he discusses the category of market value. As a matter of fact, in the few passages in which both terms do concur, the occurrence takes place in a context in which Marx stresses the divergence between market value and *market prices* (e.g., Marx 2015, 297–298). More importantly, the mere reference to another meaning for SNLT is not unequivocal evidence that it involves a *modification of the first sense*. As Grigorivici had already observed, similarly to the term "socially necessary" utilized to refer to the part of the working day during which the worker reproduces the value of their labor-power, it might as well be a case of the "use of the same technical term in different senses" (Marx 1976, 35 fn.; Grigorovici 1910, 46). Lastly, Marx´s statement that at stake is "a further developed expression of the law of value in general" (Marx 2015, 734) does not necessarily mean that a modification of the *foundations* of this law is involved. In fact, what Marx´s words *literally* refer to is the *expression* of the general law, that is, to the *self-negating form of manifestation* of the determination of value, which is indeed the case through the establishment of market prices which diverge from values.

Concerning those passages where market value is deemed to be determined by a divergence between supply and demand, it must be stressed that it is an incontrovertible fact that they are largely overshadowed by a majority of passages in the same part of the manuscript where Marx unequivocally states that a market disequilibrium exclusively affects the movement of market prices by making them diverge from market values, in turn considered as synonymous with the social value. Based on this evidence, some authors have hinted at the possibility that those apparently "market-centric" references to the determination of market value involve a lapsus by Marx or maybe errata by his editors (Yamamoto 1962, cited in Itoh and Yokokawa, 1979, 106; Salama 1978, 222 fn.; Moseley 2023b). In our view, however, another reading is possible.

In the first place, we must distinguish within the set of textual evidence usually adduced as proof of the role of effective demand in the determination of value, certain passages which entail no ambiguity whatsoever but which, we think, are quite simply misread. For instance, this is the case where Marx indicates that if any of the extreme conditions of production predominates, it is "the mass produced under [those] conditions that governs the market, or social, value." (Marx 2015, 293). As should be evident, demand plays absolutely no role in these situations. It exclusively is a matter of the proportional composition of the total mass of commodities produced in a certain branch. Furthermore, that a determinate condition of production is deemed to "govern" value does not invalidate the idea that at stake is the respective incidence on a weighted average (cf. Marx 1989a, 428–429). As already mentioned in the previous section, here the verb "govern" is used by Marx in a simple arithmetic sense. Interestingly, Carcanholo (2013, 131) suggestively notes that Marx´s precise choice of the verb "govern," which is rather unusual in his vocabulary, over the more common "determine," seems to indicate that it was not haphazard but deliberate.

Now, at this juncture, it must be duly acknowledged that there are parts of the text in which Marx unequivocally does state that effective demand determines the magnitude of market values. Yet, it is often overlooked the precise context in which those formulations occur, namely: as part of "extraordinary situations," in which "demand is *so strong*, however, that it does not contract when the price is determined by the value of the commodities produced in the worst market conditions" (Marx 2015, 289, emphasis added). In modern terminology, it would be cases of extreme price inelasticity of demand. Alternatively, Marx points to the opposite case in which supply falls below "the usual level" (Marx 2015, 289). In our view, a crucial issue here is the precise sense which Marx had in mind when referring to the "usual level" of supply and demand. This becomes clear some pages later, when Marx explicitly turns to discuss "the real difficulty in pinning down the general concepts of supply and demand" without ending up "with a tautology" (Marx 2015, 296). In that context, it transpires that when previously referring to "extraordinary situations" Marx seemed to have been pointing to a deviation from the "given scale" that expresses the "*definite quantity*" which constitutes the "customary measure" of the "*annual* production or reproduction" (Marx 2015, 296). In other words, he was not considering short-term conjunctural imbalances between supply and demand, but a more resilient disequilibrium which prevents an adjustment process through expansion/contraction of the scale of production, and which can thereby only take place through the movement of prices to a new "normal" level.

Seen in this light, this highly exceptional character of those situations casts doubts on the hypothesis that the determination of value by demand forms part of the *foundations* of the "law of value." In other words, it seems more likely that they are "divergences" from the norm, which actually have to be explained on the basis of a prior knowledge of "natural law of the equilibrium" of value (Marx 2015, 298). More importantly, in no scenario does Marx indicate that market conditions determine value but *market value*. Thus, this begs the philological question of the precise meaning of the latter in Marx´s writings, to which we now turn.

In *Theories of Surplus Value* Marx had mentioned market value for the first time, specifically as the "common value […] at which they [commodities] appear on the market," which "[e]xpressed in money" takes on the form of a common "price" (Marx 1989a, 429). On a first glance, one would be led to think that Marx is referring to what we called in the previous section "direct normal price," that is, the monetary expression of the social value of commodities. However, Marx immediately adds that "[o]ver a certain period, however, the fluctuations [of the actual market prices] equal each other out and it can be said that the average of the actual *market prices* is the market price which represents *the market value*" (Marx 1989, 429, 433; 1994, 156–157). It is noteworthy that in this latter formulation that Marx does not just refer to the market value as the simplest monetary expression of the social value, that is, as the more abstract *systematic premise* of market prices. Instead, he now refers to an *average market price* which is the *empirical result* of their oscillation, and which is deemed to "*represent*" the market value. Crucially, it must be borne in mind that the average market price is not always the immediate manifestation of the direct normal price. In effect, in the case of productions subject to natural conditions uncontrollable by capital, the average market price is regulated by the individual value of the least favorable conditions which are needed to satisfy the existing social demand. Insofar as it is a regulating price, it still is determined as a normal price, albeit not as a *direct* one (since it does not reflect the average level of labor productivity but one of the extremes). That Marx does treat the market value along these lines as a non-direct regulating price can be discerned some pages later when he discusses Ricardo´s ground-rent theory, where he observes that in the case of agriculture "the market value is *determined* by the unfertile class"(Marx 1989a, 589). Moreover, he also differentiates between this regulation of market prices and that which is simply established "because of the state of the market" (Marx 1989a, 488), elsewhere labeled as "monopoly price" (Marx 1991a, 898). This definition of market value as a "regulating" normal price, which is determined by production "in a broad sense" but without necessarily being the *direct* quantitative expression of the *social value*, is preserved throughout the whole of this manuscript (Marx 1989a, 461–63; 473–80; 485–90; 507–8; 1991b, 380; 1989b, 69–70; 516; 1994, 156). In our view, it also recurs in the manuscript which comprises Volume III of *Capital.*

Effectively, in this manuscript, Marx also starts out his exposition with a definition of market value as the direct monetary expression of the social value. But he also adds that it is "the center around which the daily market prices revolve, and at which they are balanced out in definite periods" (Marx 2015, 290). Moreover, some pages later he stresses the latter point by noting that "this average figure is by no means of merely theoretical importance. It is, rather, practically important for capital" (Marx 2015, 300; see also 294, where he refers to "average price or market value"). Against this backdrop, the claim that the market conjuncture can affect the magnitude of the market value by making it come to be regulated by "commodities produced under the worst conditions, or alternatively exceptionally favorable ones" (Marx 2015, 289), should come as no surprise. That is indeed what happens with the regulating normal price and, a fortiori, with the average market price. Now, insofar as in these passages Marx addresses what he *explicitly* considers to be "extraordinary situations" (Marx 2015, 289), he is not meticulous enough to make a *categorical distinction* between the quantitative determination of the market value regarded as the direct monetary expression of the social value (i.e., as a "direct normal price") *vis-à-vis* a broader definition as a regulating price limited by the productive capacity of the respective sphere of production which can diverge from the social value. Still, when toward the end of the manuscript he addresses the transformation of surplus profits into ground-rent, where this distinction is the norm rather than an exception, Marx leaves no doubt that the "determination by a *market value,*" understood as a regulating normal price determined by the worst conditions of production, "produces a false social value," that is, a quantitative divergence between the market value thus defined and the proper social value (Marx 2015, 817).

Lastly, we now turn to the discussion of a key paragraph which is at the center of contemporary controversies and which, moreover, involves the greatest interpretative difficulties. To begin with, let us place the said paragraph in context. The text is located where Marx announces that, up to that point, he had analyzed the "*abstract* establishment of market value," that is, by bracketing the movements of supply and demand and only considering the weight of each kind of condition of production in the total mass of commodities supplied (Marx 2015, 295). Yet, he continues, "it now becomes essential to consider the *volume*, hence the quantity, of [the corresponding] social need" (Marx 2015, 295). After a brief discussion of the scenario in which supply equals "customary demand" and in which, therefore, "the commodity is sold at its market value, however, regulated according to the variable composition of the elements forming the aggregate supply" (Marx 2015, 295), Marx moves to the examination of a scenario in which the quantity supplied diverges from "customary demand". This discussion, it must be recalled, is considered by Marx within a timeframe which corresponds to the normal *annual* scale of the reproduction process, so that the adjustment process can only occur through price variations. And he states:

> [1] If, however, the quantity supplied is less than the *demand*, or alternatively more, there will be variations of the market price from the market value. [2a] And the first variation will be that if the quantity is too small, it is always the commodities produced under the worst conditions that govern the market value, while if it is too large, it is always those produced under the best conditions; [2b] hence it is one of the two extremes that determines the market value, despite the fact that the proportions produced under the different conditions, taken by themselves, would lead to a different result. [3] If the difference between the demand for the product and the quantity produced is more significant, the market price will diverge more significantly from the market value –than through this different determination of the market value–, either upwards or downwards (Marx 2015, 295-96; translation modified based on original manuscript in Marx 1992, 260).[8]

As already mentioned, some commentators account for the potential "circulationist" implications of this paragraph by appealing to alleged lapsus or errata, whether on the part of Marx or of his editors. Thus, it is argued that all the phrases where the market value appears to change in response to a market disequilibrium would involve such an instance of lapsus or erratum. Marx must have meant that the change occurs in the "market price." Note, however, that this implies that Marx would have incurred in *three* consecutive lapsus, which, moreover, would be present in *three different phrases* (albeit only two tend to be cited, since the phrase between hyphens, which Engels did not include in his edition, but which appears in the MEGA[2], is usually overlooked). Is this hypothesis quite simply untenable? Not necessarily. However, we do think that it is highly unlikely that Marx would have made so many mistakes in a row. On the other hand, note that the hypothesis of the "triple lapsus" fails to make sense of the *counterpoint* that Marx evidently wants to make when he states that market value comes to be determined by one of the extremes, "despite the fact that the proportions produced under the different conditions, taken by themselves, would lead to a different result." A contrast between a determination of market *prices* by extreme conditions and the simplest determination of the market *value* by the weighted average of the incidence of each of the different conditions of production, would make Marx´s wording lack in all formal coherence. Or, at best, it would be an absolutely and suspiciously trivial argument. Finally, this reading proves to be even more problematic when account is taken of the phrase between hyphens that Engels omitted and where Marx stresses the sense of the counterpoint by referring to "this different determination of this market value."

---

[8] Numbering of each sentence added.

In opposition to the thesis of the "triple lapsus," the more widely accepted contemporary reading takes the paragraph at face value. On those grounds, it concludes that the passage adds to the case for the plain identification of social value and market value and, consequently, for the role of demand in its determination through the establishment of the regulating condition of production. Again, this interpretation also clashes head on against the formal coherence of the paragraph´s wording. In this case, the inconsistency is between Marx´s first claim, according to which by virtue of a market disequilibrium "there will be variations of the market price from the market value" [1], and the sentence that immediately follows [2a]. This latter sentence starts off referring to "the first variation"—which must evidently refer to the direction of the divergence between the market price and the market value—but ends up speaking about a peculiar determination of the market value as such.

How to avoid what seems like an inevitable dead-end? We think that our hypothesis about Marx´s idiosyncratic and lax usage of the term "market value," coupled with a *partial* acceptance of the "lapsus thesis," allows a reading that makes sense of a paragraph which seems to elude all formal coherence. Specifically, we concur that there might be a lapsus in the paragraph. Yet, in our view, it is located only in the *first* mention of the regulation of the market value by "the commodities produced under the worst/best conditions" in sentence [2a], which should have referred to the "market price." Thereafter, all subsequent mentions to the "market value" (sentences 2b and 3) are correct. The key, however, is the (im)precise meaning that Marx gives to that term. As already argued at length, Marx uses the category of market value not only to refer to the immediate quantitative expression of the social value, that is, to the direct normal price. Instead, he uses it more broadly also to include the regulating normal price which, under definite circumstances (notably, in agricultural production), entails a quantitative divergence from the quantity of labor that is represented in the magnitude of the social value of the product; but which, nevertheless, does reflect some of the production conditions of the respective sphere of the social division of labor.

In light of this alternative reading, the controversial paragraph seems to recover rational sense. “The first variation” would be between the market price and the market value understood as the immediate quantitative expression of the social value (i.e., according to “the proportions produced under the different conditions, taken by themselves”). Insofar as this variation is not simply short-term but, due to whatever peculiar circumstances which involve “rigidities” in the quantities supplied, persists in time, and crystallizes into an “empirical gravitational center” for the daily fluctuations of market prices, Marx appears to infer a “different determination of this market value” by one of the “extremes.” Even “more significant” variations would thereby imply market prices that lose direct connection to any of the conditions of production found in the respective sphere, that is, that differ from the market value in any of its meanings to become a so-called monopoly price.

In sum, our main argument is that the interpretative difficulties in the passages from Marx´s text which relate the market value with supply and demand conditions get resolved once we acknowledge that this category is used broadly to refer to a regulating normal price, albeit not necessarily a direct one. Along the same lines, we threw into relief that it is of paramount importance to be clear that *it therefore is not synonymous with “social value.”* While the latter is always determined solely in production according to the SNLT formed by the weighted average of the individual conditions of production in the respective branch, and constitutes the “general law of value” or “norm” that governs the “movement of prices” (Marx 2015, 288), Marx´s treatment of the “market value” in Volume III of *Capital* also encompasses further *extraordinary* mediating circumstances which involve *divergences* from the “general law,” albeit still within the limits set by the existing material conditions of production.

Now, all this begs a subsequent question. Why would Marx use the *same* category to account for *two* qualitatively different phenomena such as what we have called “direct normal price” and “regulating normal price?” At this juncture, we believe that it is suggestive that Marx coins the term “market value” as part of his critical review of Ricardo´s theoretical project aimed at offering a “unified labor theory of value” which is applicable to both manufacturing and agriculture (Marx 1989a, 428 ff.). In effect, under these peculiar premises the issue at stake no longer is to establish the connection between the magnitude of value of a commodity and SNLT but, instead, to delineate the broader nexus that all normal prices must have with some “quantity of labor expended in production.” But if this were the case, one could still wonder whether such an attempt to generalize the case of agriculture to all branches of production would entail a problematic collapse of different systematic levels of abstraction. Even more awkwardly, as attested by Marx's own exposition in Volume III, it entails lapsing into the formulation of opposite cases to what is the peculiar but real norm in agriculture, such as the permanent oversupply of commodities, which do not seem to have any practical relevance in the objective reality of the capitalist mode of production.

Conclusion

This article has revisited the Marxist debate over the meaning of SNLT against the backdrop of contemporary discussions on Marx´s value theory and the newly available evidence provided by the critical edition of the original manuscripts for *Capital.* We have seen that three main perspectives can be discerned. The "circulationist" one considers that SNLT represents the amount of social labor validated by effective demand on the market. The "production-centered" approach maintains that it is constituted through an average of the conditions of production prevailing in the respective sphere. Finally, there is an "intermediate" position which argues that it expresses the regulating condition of production which is in turn determined by effective demand. After critically reviewing the different positions in the debate, we concluded that none of them offers an explanation which is consistent with both the simplest determinations of value and Marx´s writings on the subject.

Our own key argument was that SNLT, as the quantitative aspect of the substance of value, expresses the norm of the productivity of labor which is established through the diversity of production conditions under the command of the multiple individual capitals in a certain branch of social labor. In turn, we submitted that the different price-forms are the "distorted" (i.e., self-negated) modes in and through which the former *content* is *expressed*, with varying degrees of mediation. Furthermore, this latter process mediates the indirect imposition of the norm which constitutes the proportional allocation of the total social labor among the different spheres of production.

As for Marx´s textual legacy, we pointed out that he does refer to this other norm in the quantitative regulation of social labor as a "second sense" of SNLT. But we disputed the claim that it entails a modification of its "first sense." Instead, we maintained that it is a case of usage of the same "technical term" for different purposes. Moreover, concerning the passages in Volume III of *Capital* where Marx relates the determination of the magnitude of the market value with the volume of effective demand, our central claim was that the former term is not synonymous with the social value. However, in chapter 10 of Volume III Marx arguably tended to conflate the two categories. More specifically, Marx understands the market value as the monetary expression of the social value in the form of a regulating normal price, be it in a quantitatively direct or unmodified fashion (as happens in normal circumstances), be it as a regulating normal price within the range of those determined by at least one of the conditions of production prevailing in a certain industry. Seen in this wider light, its determination does incorporate the mediation of (highly exceptional) conditions of circulation. This is what sets it apart from the social value, whose constitution as the purely social representation of the materiality of the privately performed socially necessary abstract labor, takes place exclusively in the sphere of production.

Global Commodity Chains and the Marxian Law of Value

Guido Starosta

Politics, School of Social Sciences, University of Manchester, UK;
guido.starosta@manchester.ac.uk

Abstract: This paper develops a Marxian critique of the "global commodity chain" (GCC) paradigm. It is argued that this approach fails to provide an actual explanation of the phenomenon it sets about to investigate. Instead, it offers a typological description of the immediate manifestations of the determinations at stake. As a consequence, the GCC approach one-sidedly conceptualises the relations among individual capitals within a commodity chain as the simple result of relations of power (or co-operation), that is, of direct social relations. By contrast, this paper argues that the latter are concrete mediations of the inner laws regulating the indirect social relations among individual capitals: the process of global competition through which the formation of the general rate of profit asserts itself. On this basis, it develops an alternative account of the social determinations underlying the genesis, structure and evolving configuration of GCCs as an expression of the unfolding of the Marxian "law of value".

Keywords: global commodity chains, Marx, law of value, capitalist competition

> . . .and all science would be superfluous if the form of appearance of things directly coincided with their essence (Marx 1981:956).

Introduction

The global commodity chain (GCC) approach can be regarded as a highly influential framework for the study of contemporary economic processes to have emerged out of the academic debates around the so-called "globalisation" question.[1] It is part of a growing number of diverse traditions that have been converging into what could be labelled a "network-led development paradigm" (Sturgeon 1998). These related approaches see the problematic of development through the lenses of some variant of the concepts of "chains" or "networks" (Henderson et al 2002:448).[2] Without wanting to downplay the differences between the varied intellectual traditions in this broad group of perspectives, they all share a common set of assumptions and concerns. First, they all recognise the novelty of phenomena generally associated with the "globalisation" of the capitalist economy, which they define in terms of the emergence of a pattern of global dispersion with functional integration of economic activities (Dicken 2003:12). Second, they see the configuration of global production networks of firms as fundamental

drivers of these economic transformations and, therefore, as the context in which to rethink the problematic of development (Yeung 2007:1). In particular, participation in these networks or chains is considered to be a central determining factor of different developmental outcomes by providing opportunities for "upgrading" of firms that can spill over to the rest of the national economy (Kaplinsky 2000; see Bair 2005:167ff, for a critical assessment of the concept of upgrading).

This focus on the sectorally specific structure and dynamics of global industries could be said to resonate with the broader resurgence of interest in the economic, cultural and spatial "life" of particular commodities among geographers (Bridge and Smith 2003; Castree 2001). In this sense, Leslie and Reimer (1999) identify the GCC approach as one of three perspectives that have recently revived academic attention to the specificities of different sectors, the other two being the systems of provision approach mainly associated with Fine and Leopold (Fine and Leopold 1993) and the commodity circuits found, for instance, in Cook and Crang's work on "circuits of culinary culture" (Cook and Crang 1996). But while these latter two groups of literature tend to concentrate on the production–consumption linkage (and, as a consequence, on the nature of the connection between "economy" and "culture" in capitalism), it is the former strand of research that fundamentally puts issues of economic and industrial organisation at the centre of the inquiry (Smith et al 2002). Insofar as this paper is concerned with organisational aspects of the changing forms of global competition, I shall therefore restrict the critical discussion that follows to the GCC approach.

There is no doubt that studies informed by the GCC approach have provided rich empirical descriptions of the functional articulation of particular branches of industry dispersed across the globe. In effect, research stemming from the GCC tradition offers very detailed and informative accounts of the current forms of intra-capitalist competition in different commodity chains. Those studies can therefore be taken as a useful empirical starting point for the investigation of the more general determinations that underlie the relationships among the different individual capitals along each chain. However, some further questions arise concerning its contribution to our comprehension of the contemporary forms of global capital accumulation. In the first place, a critical assessment of the GCC approach should evaluate its merits as a framework for the study of international development. Such an overall assessment of the GCC approach as a tool for the comprehension of uneven development in global capitalism is not, however, the path that I shall follow in this paper.[3]

My aim here is much more modest but, at the same time, focuses on an aspect that has remained unexplored in the critical literature: this paper subjects to critical scrutiny the very concept of commodity chain

Journal compilation © 2010 Editorial Board of *Antipode*.

through the lens of the Marxian "law of value". Given this limited scope, the paper will only examine one of the two constitutive components of the notion of GCCs. Thus, the discussion focuses on the determinations of the "chain form" taken by the current forms of capitalist competition at the expense of analytically "bracketing" its global dimension. To freely borrow a useful distinction from Yeung (2007:4), I centre the examination of GCCs on the "organisational fix" in GCCs and not so much on its "spatial fix". While the latter idea originally developed by Harvey (2006) refers to the geographical relocation undertaken by capital in order to maintain its profitability, the former tries to capture the way in which global lead firms reorganise their network of suppliers in order to maximise their valorisation. As Harvey himself remarks in the *Limits to Capital*, even if it does not provide a full picture of the social processes at stake, a separate engagement with the changing organisational arrangements of capital can nonetheless offer valuable insights into what is a distinctive concrete form taken by the accumulation process (Harvey 2006:139).

Through a critical appraisal of the general foundations of the GCC approach, I make the following two main points. In a more critical vein, I shall argue that despite its informative character, the GCC approach does not actually provide an explanation of the very specific phenomenon that it sets to investigate. What commodity chain studies do is simply to offer, through an essentially inductive-empiricist methodology, a typological description of the immediate outer manifestations of the determinations at stake. This failure firmly to explain the nature of GCCs is expressed, for instance, in the disjuncture between the portrayal of the particular dynamics internal to each industry and the general dynamics of the "system as a whole". Secondly, and more constructively, this paper offers an alternative account of the social determinations underlying the genesis, structure and evolving configuration of GCCs on the basis of the Marxian critique of political economy. In this way, I recast the phenomenon of GCCs by putting forward more solid theoretical foundations for the comprehension of this novel form of capitalist competition on a world scale.

In this endeavour, I intend to echo Neil Smith's appeal for a "return to theory" in radical economic geography (Smith 1989). As he argued in the late 1980s, much of the work among critical geographers tended to react to the abstract and formalistic general models of traditional location theory by re-emphasising empirical research on specific industries and places and aiming at capturing the detail and complexity of particular cases. While there is much to commend in this preoccupation with particularity, Smith reported how this shift towards empirical research had eventually come at the expense of a renunciation of theory and had dangerously slipped into a new empiricism that was incapable of shedding light on the general movement involved in the changing

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

uneven geography of capitalism (Smith 1989:154–156). More recently, Jamie Gough noted how this theoretical gap still remained more than 10 years after Smith's original call and reinstated the need to found the understanding of scalar economic relationships on the fundamental processes of capitalist economies (Gough 2003:25). Difference or particularity, he further argued, should be comprehended out of the contradictory development of the general movement (as differentiation of a contradictory totality), rather than as an irreducible and self-subsistent singularity that escapes determination by the motion of the fundamental social forms of capitalist production (Gough 2003:29). As Hudson puts it in a recent appraisal of the state of progressive radical geography, the Marxian "law of value" remains vital to "elucidate the decisive social relationships specific to capitalism and to the contemporary world" (Hudson 2006:379); and, one could add following Harvey's reflections on the Marxian notion of the capital circulation process (Harvey 1996:64–66), as the fundamental general social process that gives unity and content to the different particular moments or differentiations of the movement of modern social life. This obviously includes a phenomenon as concrete as the formation and dynamics of GCCs, whose current study can arguably be shown to suffer from all the shortcomings and risks of empiricism denounced by Neil Smith 20 years ago. This paper thus takes up this intellectual challenge and offers some elements for filling this theoretical gap in the study of GCCs.

An Outline of the GCC Approach

The concept of GCCs aims to capture the novel type of inter-firm linkages that articulate the functional integration of globally dispersed activities that characterise the present era of globalisation (Gereffi 1994:96). As a unit of analysis, the concept of GCC refers to:

> . . . the full range of activities, *including coordination*, that are required to bring a specific product from its conception to its end use and beyond. This includes activities such as design, production, marketing, distribution, support to the final consumer, and governance of the entire process (Gibbon and Ponte 2005:77).

As Bernstein and Campling note (2006b:439), the main focus of commodity chain analysis lies in the realm of the relation between individual capitals. In particular, GCC research has attempted to illuminate the different types of international network forms that co-ordinate the division of labour underlying each final product and that cannot be grasped through the traditional binary opposition between "market" and "hierarchy" (Gereffi, Humphrey and Sturgeon 2005; Palpacuer and Parisotto 2003). As Gereffi, Humphrey and Sturgeon note against the predictions of transaction cost approaches and building on the

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

insights of network theories, "co-ordination and control of global-scale production systems, despite their complexity, can be achieved without direct ownership" (2005:81). These different ways of articulating complex global production systems are reflected in varied and shifting governance structures.

The concept of governance was originally devised to depict the diversity of authority and power relationships that give overall co-ordination to the division of labour within the commodity chain. Specifically, the governance structure was seen by Gereffi as socially mediating the material interdependency that characterises the "input–output structure" of each GCC (ie the sequence of value-adding economic activities), insofar as it determines "how financial, material, and human resources are allocated and flow within a chain" (Gereffi 1994:97). This was all the more necessary since that input–output structure had a globally dispersed coverage. In turn, this concept of governance is intimately connected with the concept of the "driveness" of GCCs or, what amounts to the same thing, the role of lead firms as "chain drivers". These are the most powerful firms which effectively command the overall commodity chain co-ordination due to their ability to exert control over the other nodes of the network of firms (Bair and Dussel Peters 2006; Gereffi 2001:1622). In this early formulation, the concept of GCC was underpinned by a "strong" notion of chain drivenness (Bernstein and Campling 2006a), in which lead firms strategically exerted their power in order to configure GCCs for the benefit of their own profitability. In this sense, GCC analysis was seen to be a methodology that could shed light on the intrinsic connection between power and profits. According to Gereffi, "profitability is greatest in the relatively concentrated segments of global commodity chains characterized by high barrier to the entry of new firms" (2001:1620). In "apportioning roles to key players" within a network of firms (Kaplinsky 2000), lead firms end up regulating how much profit accrues at each stage of the chain (Gereffi 2001:1620).

Now what is the source or material basis of the relative power of each firm (and in particular that of chain drivers)? The answer to this question leads us to what is another key element of the GCC approach, namely, the related concepts of economic rents and barriers to entry (Kaplinsky 2000:122). Lead firms obtain their exceptional profitability as a result of their capacity to generate different kinds of rents, which are defined as "returns from scarce assets" (Gereffi 2001:1620). These scarce assets, which can be tangible (machinery), intangible (brands) or intermediate (marketing skills), provide the foundation for the emergence of barriers to entry and thereby give rise to those different sorts of extraordinary economic rents: technological, organisational, brand-name, relational and so on (Gereffi 2001:1621). Moreover, these assets provide the basis for the definition of the core competencies that lead firms will

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

tend to monopolise (eg R&D, design, manufacturing, marketing and so on).

Although there is no a priori precise node in the chain where a lead firm will tend to be situated (ie lead firms are not necessarily involved in the making of the finished product and can be located upstream or downstream from manufacturing, see Gereffi 2001:1622), early GCC empirical research claimed that there were two main types of commodity chains: producer-driven commodity chains (PDCCs) and buyer-driven commodity chains (BDCCs). The former tend to predominate in capital and technology intensive industries (automobiles, computers, aircraft and electrical machinery) and generally involve a powerful manufacturer that has tight control over a vertically organised network of suppliers consisting of several tiers. Core competencies are usually final assembly and R&D (Bair 2005:159). BDCCs tend to predominate in lighter, labour-intensive industries (apparel, toys, footwear, consumer electronics); their organisation is generally under the command of "big buyers" (designers, retailers, brand-name firms) that monopolise the functions of design, marketing and distribution, and that outsource the whole manufacturing stage (as opposed to components) to a more horizontally organised and decentralised network of small and medium-sized firms (Bair 2005:159).

Subsequently, partly as a response to criticisms of the simplistic nature of the PDCC/BDCC dichotomy and partly as a result of further empirical observation of different and changing configurations of commodity chains, Gereffi and his colleagues came up with a more complex typology involving five different types of chain governance (Gereffi et al 2005).[4] This five-fold typology also reflects the more recent incorporation into the GCC approach of insights from the new economic sociology, with its emphasis on notions like "embeddedness" and "networks".[5] In this new characterisation of types of GCC, governance structures "move along a spectrum that starts with un-embedded 'arms-length' market relations, moves through modular, relational and captive value chains, and culminates in 'hierarchy', which relates to the complete vertical integration of production within a unitary transnational enterprise" (Taylor 2007:534).[6] The constitution of each particular type of commodity chain is a function of three key determinants: the complexity of transactions, the ability to codify transactions, and the capabilities in the supply-base (Gereffi et al 2005:87). In turn, each of the five governance types along the spectrum from market to hierarchy involves increasing degrees of explicit co-ordination and power asymmetry (Gereffi et al 2005:87). In consonance with the new economic sociology literature, this new typology emphasises that the embeddedness of economic transactions in broader social relations leads to the co-ordination of inter-firm networks not only through sheer power relations, but also through "trust" and "mutual co-operation". Still, the

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

point remains that in all cases the emphasis lies in the way in which these networks of firms are socially regulated through a certain degree of what GCC theorists call "explicit co-ordination", that is, they are not completely evanescent and impersonal. In other words, linkages between firms in commodity chains are regulated through relatively stable direct (ie conscious and voluntary) social relations.

Now there is no doubt that studies informed by the GCC approach have provided rich empirical descriptions of the functional articulation of particular branches of industry dispersed across the globe. In effect, research stemming from the GCC tradition offers very detailed and informative accounts of the current forms of intra-capitalist competition in the different "commodity chains". However, a closer scrutiny of the foundations of the theoretical edifice of the GCC approach suggests that it does not actually provide a satisfactory explanation of the constitution and dynamics of commodity chains. In the next section, I substantiate this point through a more critical engagement with the concept of GCC with a focus on the foundational contributions to the GCC approach, that is, when it was still explicitly formulated as a theoretical development within the world-systems tradition. As I shall argue, the theoretical difficulties in connecting the particular characteristics of GCCs with the general dynamics of capital as a whole do not only stem from its more recent shift to a meso/micro level of analysis, as reported by Bair (2005) in her survey of the intellectual evolution of the GCC paradigm (through the incorporation of insights from the new economic sociology and management/industrial organisation theory literature). Rather, I argue that those weaknesses can be traced back to the original formulations of the GCC approach, that is, when it was still explicitly concerned with establishing a firm connection between the social constitution of "globally dispersed networks of firms" and the "structural properties" of the world economy as a whole.[7]

The Limits of the GCC Framework

Although rarely noted by commentators, it is remarkable that one of the founding works in the GCC paradigm by Gereffi, Korzeniewicz and Korzeniewicz (1994) explicitly situated the emerging approach broadly within the intellectual lineage of monopoly capital theory; or rather, in what the world-systems approach shared with it.[8] Thus, building on the contribution to the book *Commodity Chains and Global Capitalism* by Hopkins and Wallerstein (1994), the editors of the volume stated that "monopoly and competition are key to understanding the distribution of wealth among the nodes in a commodity chain" (Gereffi et al 1994:2). The argument was that competitive pressures were unevenly distributed along the chain. While innovation or, more generally, the possession of "strategic assets" allowed core-like nodes in the chains to be relatively

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

insulated from the forces of capitalist competition, peripheral firms bore the transfer of competitive pressures onto their shoulders (Gereffi et al 1994:3). Accordingly, profitability was said to be distributed along the chain following the relative intensity of competition within different nodes (Gereffi et al 1994:4). Moreover, the possession of strategic assets gave those core firms not only higher profitability (due to greater "market power"), but also the overall power to control forward and backward linkages along the chain.[9]

My claim is that the GCC approach is ill-equipped to explain this phenomenon, which is so central to its very own object of inquiry. In effect, it is to be noted that the above account of the formation and dynamics of commodity chains simply presupposes what needs to be explained. Thus, the differential power among firms to appropriate profits is seen to derive from the capacity of some capitals to generate barriers to entry, which is in turn premised on their relative monopoly over some strategic "scarce asset", that is, one which expresses the capacity to actively participate in the development of the forces of production. But surely the determination of those assets as relatively "scarce" presupposes that other firms within the chain are systematically unable to have their own strategic assets, that is, they lack the magnitude of capital necessary to generate their own barriers to entry. Otherwise, all firms along the chain would have their own "strategic asset", making the possession of those assets cease to be relatively scarce, and leading to the disappearance of the material basis for the differential capacity to command the chain and appropriate higher profits. GCC analysis simply assumes the power differential among capitals and then "explains" the emergence and dynamics of commodity chains on the basis of it as the strategic choice made by lead firms through which they arbitrarily impose the particular conditions for the overall circulation (hence valorisation) of all other capitals along the chain. But although this might be descriptively accurate, it simply presupposes that all other capitals do not have the power to contest that organisational leadership and will therefore have no choice but submissively to accept to valorise at a lower rate of profit. As we can see, this inability to provide a sound explanation of its very object of inquiry has accompanied the GCC approach from its world-systems origins, broadly based as it was in monopoly capital theory.

The rest of the paper argues that the Marxian "law of value" can provide firmer foundations for the comprehension of the nature and dynamics of GCCs. As Marcus Taylor (2007) notes in a recent attempt to conceptualise GCCs from the perspective of the Marxian critique of political economy, this endeavour requires us to rethink the precise relation between those embedded economic activities that GCC research so vividly describes and the more general global dynamics

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

of capital accumulation. “Embedded” social relations, Taylor rightly points out, cannot be understood as self-subsistent constellations but as moments in a circuit of capital spanning production and circulation (Taylor 2007:536). More concretely, the fundamental question lies in the connection between the essentially indirect nature of the general social relation that regulates capitalist production, and the varied direct social relations through which the establishment of the unity of the former is eventually mediated at particular nodes of social division of labour. In other words, what needs to be uncovered is the inner connection between the self-expansion of capital on an ever increasing scale through the unfolding of the “law of value” (the content) and the relatively enduring direct social relations between particular individual capitals within a chain, that is, “embeddeness” and “networks” (the form). The problem with the GCC approach in all of its variants is that it does not grasp the relations among individual capitals beyond their immediate appearances. It is thereby unable to uncover the content of the phenomenon under investigation behind its outward manifestations and actually inverts the latter into the very cause of the phenomenon itself. Thus, it sees the constitution of commodity chains as essentially governed by direct social relations of command (or co-operation). This in turn leads to the inability of GCC research to comprehend the underlying unity of the process of capitalist competition and its inner laws and, therefore, to an inability to connect the particular dimensions of GCCs (including the embedded or direct social relations that mediate the material interdependency among its participants) with the general dynamics of the “system as a whole”. This connection, I argue below, is precisely what the Marxian “law of value” can help elucidate.

GCCs as an Inner Moment of the Process of Capital Circulation

Some first steps in the direction of recasting GCCs through the lenses of the Marxian critique of political economy have been already made by radical economic geographers. For example, Hudson rightly remarks that to “conceptualise production in terms of GPNs [Global Production Networks, GS] is to do no more—and no less—than to recognize the practical realities of capitalist economies”, which are fundamentally “centred upon commodity production, the production of things with the intention of sale in markets, and value expansion via the production and realization of surplus-value” (Hudson 2008:425). However, this is only implicit in the GCC approach and needs to be made explicit by extending that framework “beyond “the commodity” per se and towards the commodity as an embodied form of value (Smith et al 1999). The “biographies” of commodities are in this light the way in which they

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

move within and beyond the circuits of individual capitals (Hudson 2001, 2008).

I agree that this is the correct starting point for a Marxian take on the phenomenon of GCCs, insofar as it locates the latter within the general nature of capital as self-expanding value. However, I think that there is still a theoretical gap to be filled by unfolding the precise mediations that connect this more abstract determination of capital with the systematically more concrete level of abstraction at which the phenomenon of commodity chains has to be located, namely, the relations of cross-branch competition between individual capitals (ie capitalist firms). The question that needs to be addressed is why and how the unity of the circulation process of capital is achieved through the characteristic relations between individual capitals that structure commodity chains. Let me expand and reframe this question by firstly looking more closely at the general nature of capital.

One of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither simply a thing (for example, the instruments of production), nor productive unit or legal entity (ie a firm), nor a social grouping sharing common characteristics and interests (ie "business" or "the bourgeoisie"). In its general determination as self-valorising value, capital is actually a materialised social relation between commodity owners differentiated into social classes which, in its fully developed form as total social capital, becomes inverted into the very (alienated) subject of the process of social reproduction and its expansion in its unity (Marx 1976:763).[10] Thus, capital is essentially the movement of self-expansion of the objectified general social relation between private and independent human beings which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976:723–724; 1978:185). All moments of the human life process thus become inverted into material bearers of the lifecycle of capital or, as Harvey highlights, they become forms assumed by the flow of value in its circulatory process (Harvey 1996:63). Subsumed under the capital form, the alienated content of social life becomes the production of surplus value or the formally boundless quantitative progression of the general reified form of social mediation (Marx 1976:251–257).

Although this content governs the movement of capital as a whole or as an alienated collective power, the total social capital is nonetheless the product of the private and independent form taken by social labour. The general unity of the movement of the total social capital cannot be established immediately. It is thereby indirectly established through the exchange of commodities resulting from the apparently autonomous actions of individual capitals in competition with each other, as each of them pursues the maximisation of its profitability through the expanded reproduction of their formally independent cycles of valorisation. In

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

their simplest form, those cycles can be represented through the well-known general formula of capital.

$$M - C \left\langle \begin{matrix} LP \\ Mp \end{matrix} \right. \ldots P \ldots C' - M'$$

where *M* is money capital, *C* is commodity capital, *P* is productive capital, *L* is labour power, *Mp* is means of production, – is circulation process and "..." represents production process.

More specifically, the concrete form in which individual capitals assert their class unity as "aliquot parts" of the total social capital is the process of formation of the general rate of profit (Marx 1981:298–300, 312). This is the inner or essential determination of the general social relation between capitalist firms. However, the concrete realisation of this inner determination could be mediated under certain circumstances by the establishment of relatively stable direct social relations between certain individual capitals; for instance, relations of hierarchy and power such as those that structure GCCs. The elucidation of those determinate circumstances is precisely what a critical investigation of the social constitution of GCCs should be directed towards. The intellectual challenge, then, is to comprehend the differentiation of the valorisation capacities of individual capitals along the chain as an expression of the global unfolding of the "law of value", that is, through the formation of the general "world market rate of profit" (Bonefeld 2006:51). In the next two sections, I show why and how the direct social relations governing GCCs are concrete mediations in the process of competition through which the formation of general rate of profit—and therefore, the unity of the movement of the total social capital—asserts itself.

Capitalist Competition and the Differentiation of Individual Capitals

In *Capital* Marx develops the inner determinations regulating the competition among individual capitals of different branches of the division of social labour through his discussion of the formation of the general rate of profit and the "transformation of values into prices of production".[11] As Marx argues in those pages, the formation of the general rate of profit takes the concrete form of a tendential equalisation of average rates of profit across the different branches of industry. This would seem to leave us disarmed in the face of the central feature of GCCs that needs to be explained: the configuration of chains with capitals of different profitability and under the overall command of a lead firm that systematically appropriates extraordinarily high profits.

And yet I do not think that this should be the end of the story, a fatal blow for the potentiality of the critique of political economy to

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

cast light on contemporary forms taken by global capitalist competition and described in the GCC literature. Drawing on the work of Iñigo Carrera (2003:ch 5) I argue that what Marx provides in those pages is the simpler or more abstract form taken by the formation of the general rate of profit. The affirmation of the unity of the total social capital through the determination of its private fragments as "equally valorised values" (Iñigo Carrera 1995) is further realised in the form of its self-negation, that is, by differentiating their valorisation capacities. Here it is important to emphasise that this process of differentiation does not constitute, as monopoly capital theories (the GCC approach among them) would have it, the absolute opposite of the formation of a general rate of profit as the fundamental law regulating the relation between individual capitals. Instead, it involves a further concretisation of that very same law.[12]

The key to these more concrete determinations, however, are not to be found where Marx explicitly addresses the competition among the multiplicity of capitals comprising the total capital of society. But they can be found several pages later in volume 3 of *Capital*. Specifically, Marx hints at this problem in the context of his discussion of the genesis of capitalist ground rent when he is unfolding the peculiarities of small-scale peasant ownership (Marx 1981:940ff). There Marx unfolds the category of "small capital" and shows that its valorisation is not regulated in the same form as normal capitals. More generally, what Marx effectively offers us in those pages is the basic elements to further develop the determinations of the qualitative differentiation between normal and small capitals which, as shown below, will prove of paramount importance for the explanation of GCCs on the basis of the law of value. While Marx only unfolds those determinations in the specific context of agrarian capital (ie industrial capital valorised in agriculture), the work of Iñigo Carrera (2003:ch 5) insightfully shows that their applicability is broader and can actually be generalised to industrial capital as a whole. Moreover, he draws additional implications from the reproduction of small capitals which, I believe, cast further light on the constitution of commodity chains.

As has been forcefully argued by many Marxist scholars (Shaikh 2006; Weeks 2001), the dynamics of capitalist competition that mediate the production of relative surplus value by the total social capital is not the judicious and orderly social process ideologically presented by neoclassical economics. Rather, it is marked by a fierce warfare that results in the uneven development of the productive forces within and across branches of production (Smith 2008). Individual capitals that cannot keep up with the demands of the competitive battle (essentially and ultimately—though not exclusively—revolving around the increase of the productivity of labour), eventually face bankruptcy and displacement from the market. This is the concrete form that mediates the process of

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

concentration and centralisation of capital that Marx emphasised as characterising the dynamics of the accumulation of capital through the production of relative surplus value (Marx 1976:776–777). However, as Iñigo Carrera points out (2003:124), this process does not necessarily take the simple form portrayed by Marx. In effect, the liquidation of individual capitals that are unable to keep up with the scale needed to set into motion the socially normal methods of production (ie to function as normal or average capitals) does not have to be the immediate outcome of their defeat in the competitive struggle. Besides the recourse to other temporary sources of competitiveness like the abnormal extension of the working day or intensification of labour (Clarke 1999), there are still other ways in which they can extend their agony. The key to this expanded lifespan lies in the determinations of *small* capitals that I mentioned above.

In effect, I have pointed out that the valorisation of agricultural small capitals is not regulated by the average rate of profit of normal capitals. Instead, it is regulated either by the value of the means of subsistence needed for the material reproduction of the peasant or, additionally, by the interest paid on the price of land. This differential valorisation capacity can be generalised for all industrial capitals. In this case, only in very extreme circumstances will the rate of valorisation fall down to the equivalent of the wage that the small capitalist receives (i.e., the case of the family business whose owner is on the verge of proletarianisation). More generally, the rate of valorisation of small capitals in non-agricultural branches of production is usually regulated by the interest rate on the liquidation value of their productive assets (Iñigo Carrera 2003:124). In other words, their valorisation capacity is determined by the rate of interest that those capitals of restricted magnitude could yield if they closed down business and were turned into interest-bearing capitals. Accordingly, this rate of valorisation will vary with the specific concrete magnitude of different small capitals, since the aforementioned rate of interest will vary in each case.[13] Small capitals actually constitute a stratification of capitals of different magnitudes, some of which might only slightly differ from normal capitals, to the point of being imperceptible through impressionistic observation (Iñigo Carrera 2003:124). This means that, at first sight, some small capitals can look impressively "big". The point is that they nonetheless do not reach the specific magnitude needed to be turned into normal capitals, that is, they do not reach the "definite minimum of capital [that] is required in each line of business to produce commodities at their price of production" (Marx 1981:843).

The crucial point for this discussion is the following: if, as is likely to be the case, the rate of interest tends to be below the general rate of profit, then the higher costs springing from the smaller scale and/or the obsolete means of production used could be compensated by the lower

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

rate of profit. The limit to the survival of small capitals is thereby given by the extent to which the price regulating their valorisation (determined by their cost price plus the interest rate on the liquidation value of their respective assets) manages not to rise above the price of production regulating the valorisation of normal capitals.[14] This strictly determined limit is therefore subject to the general development of the productivity of labour in each particular branch of industry, which in turn expresses the changing pace and forms of production of relative surplus value by the total social capital. Moreover, inasmuch as the concentration and centralisation of capital nonetheless marches forward, the limit for the subsistence of small capitals moves continuously upwards over time. But as long as the pace of the increase of the productivity of labour determines a normal price of production that does not fall below the price that regulates the valorisation of small capitals, the latter can continue accumulating despite their inability to keep up with the development of the capitalist productive forces due to their reduced magnitude.

In fact, if the price that regulates the valorisation of small capitals is actually lower than the normal price of production that regulates the valorisation of normal or average capitals, the latter become effectively excluded from those branches of social production. What we effectively have here is an "entry barrier" for normal capitals, which are unable to compete with smaller capitals that set into motion a lower productivity of labour but which compensate those higher costs through a considerably lower rate of profit. And this has fundamental consequences for the development of the productive forces of social labour. To put it simply, since small capitals are by nature incapable of being at the vanguard of technological development, their reproduction and dominance in whole branches of production acts as a reactionary barrier to the unfolding of the plenitude of the potentialities of the revolutionary transformation of the material conditions of social labour through the automation process.

The reproduction of small capitals has another implication which is crucial for the comprehension of the formation of commodity chains: the release of surplus value by small capitals (Iñigo Carrera 2003:126ff). If concrete circumstances are such that small capitals manage to sell their commodities at a price that stands above the one determined by their specific rate of valorisation but below the price of production of normal capitals, then a potential surplus profit emerges.[15] However, although this surplus profit is borne by the commodities produced by small capitals, their competition over that extraordinary mass of abstract social wealth eventually leads them to expand production and drives their prices down to a level determined by their specific rate of valorisation.

Does this mean that the surplus profit vanishes into thin air? Certainly not. Although it slips through the fingers of small capitals, it ends up in the hands of some of the normal capitals that valorise in directly neighbouring branches of the division of labour and with which they

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

relate in the sphere of circulation. Assuming, for the sake of argument, that small capitals are suppliers of inputs for those normal capitals, the latter will benefit from a permanent flow of extra surplus value derived from the purchase of inputs at prices below their normal price of production (ie at a "pseudo" price of production). In turn, this means that those successful normal capitals that end up monopolising the market relation with small suppliers will systematically obtain a higher than normal rate of profit.[16]

What are the implications of all these further mediations in the concrete forms taken by the competition among individual capitals beyond the simple equalisation of the average rates of profit described by Marx? In a nutshell, we can now see that the unfolding of the intra-capitalist competitive battle generates a three-fold differentiation among individual capitals. First, there are normal or average capitals whose rate of profit is tendentially equalised at the level of the general rate of profit. Second, there are small capitals, the losers in the competitive war that nonetheless manage to extend their lifespan through systematic valorisation at a rate of profit below the general one. Third, there are some normal capitals that, through the appropriation of the surplus profit freed up by small capitals, systematically valorise at higher than average concrete rates of profit. I shall term this latter kind of individual capital enhanced normal capital.[17]

In brief, a hierarchy of individual capitals with differential valorisation powers emerges out of the immanent dynamics of competition that mediate the establishment of the unity of social capital as the concrete subject of the exploitation of the collective labourer. Two important points should be emphasised in this regard. First, this is not simply a short-term phenomenon but can reproduce itself over relatively long periods of time. Still, this differentiation cannot persist indefinitely as the aforementioned objective limits to the reproduction of small capitals are eventually reached. The precise forms and timing of its internal dynamics ultimately depend on the pace of the contradictory development of the productive forces of social labour as an attribute of the total social capital, that is, on the concrete forms taken by the production of relative surplus-value on a world scale in the course of capitalist development.

Second, this hierarchical differentiation of capital does not derive from, or result in, the suspension or transcendence of the general law regulating the competition process, that is, the capitalist law of value or the formation of the general rate of profit, through the emergence of a "monopoly sector" that stands above and dominates a "competitive" one. Quite to the contrary, as I hope to have shown: it is the concrete expression of the pure unfolding of the formation of the general rate of profit beyond its simpler forms (as discussed by Marx in *Capital*). The law of value continues to operate with full force across the whole

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

capitalist economy. Moreover, the above discussion implies that value is not simply created within each chain or network of firms and then contingently captured in different degrees by each participant, as implied by GCC analysts. Instead, value is created by the living labour of workers in the economy as a whole and appropriated through the objective process of formation of the general rate of profit by each individual capital.

What follows from this is that the power relations among individual capitals are not, as GCC analysts would have it, the cause of their differential valorisation capacities. It is the other way round: because the law regulating the competition process—the formation of the general rate of profit—takes concrete shape through the differentiation of the concrete valorisation capacities of each kind of individual capital, the indirect social nexus among the latter is expressed through unequal or hierarchical relations. This means that although the establishment of the concrete rate of profit of each capital in the chain is mediated by their respective exercise of power in the sphere of circulation (thereby appearing as the simple outcome of those unequal market relations, i.e. as a relation of subordination), it is actually strictly and objectively determined in accordance to the laws of movement of capital as whole.

Rethinking the Nature of Power in GCCs

This latter point bears on a more general question that has recently caught the attention of geographers investigating the dynamics of GCCs, namely, the nature of power in networks of firms (Hess 2008; Rutherford and Holmes 2008; Smith 2003). The debate can be seen as motivated in part by the dissatisfaction with what has been considered as a reified understanding of power in Marxist or structuralist approaches. This allegedly is a view of power as "thing" that can be possessed and used to advance certain vested interests, and which exists in particular, privileged social loci (for instance, in the headquarters of TNCs or in the state) (Marques 2007). It is, as post-structuralists would have it, a "centred" conception of power. In light of the shortcomings of this traditional Marxist view to make sense of the diversity and apparent contingency of power relations in production networks, many geographers have tended to adopt a more "decentred" or "diffuse" view of power as immanent to the singularity of the specific social field in which it is exercised or, alternatively, as a relational effect of social interaction (Allen 2003). The latter view in particular has been highly influential among proponents of the GPN approach who draw on action network theory (ANT) (Coe et al 2008). Finally, some scholars have tried to find a compromise between the two extremes of "structural determination" and "relational contingency" through either a "weak" version of ANT (Castree 2002; Smith 2003) or by recourse to insights

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

from critical realism (Marques 2007; Rutherford and Holmes 2008; Sayer 2004).

I believe that the approach developed in this paper offers a perspective on power in commodity chains which, although drawing on the Marxian critique of political economy, differs from what is usually depicted as the Marxist position in the debate, namely, that the dynamics of GCCs or GPNs are directly controlled at will by the (structurally determined) economic authority and power of TNCs, and maybe indirectly through their privileged influence on the policies of a relatively autonomous state (Rutherford and Holmes 2008). More generally, it suggests that the whole terms of the debate on power in commodity chains or production networks might be in need of rethinking. It seems to me that the prevailing understandings of power and domination tend to grasp them, as Postone puts it in relation to what he calls "traditional" Marxism, "in terms of the concrete domination of social groupings or of institutional agencies of the state and/or the economy" (Postone 1998:62). This not only applies to those "structural" approaches that focus on the "idea that we are under the control of a political or economic authority" (Allen 2004:23). Inasmuch as they focus on the concrete immediacy of direct social relations, it also applies to relational approaches as well.

My own approach points to a different understanding of the inner or essential nature of power and domination in capitalism. As Postone (1998:62) notes, what is specific to capitalist domination is its impersonal and abstract character. This is not simply the domination of one kind of actor over another (ie the command of lead firms over the network of suppliers emphasised by structuralist and realist approaches). But neither is it the open relational effect of the contingent mobilisation of resources by actors in a network. Rather, it is the abstract rule of all "actors" by the autonomised movement of the general objectified form of social mediation, namely, value (Iñigo Carrera 2003). As Marx puts it in volume 2 of *Capital*, "the movement of industrial capital is this abstraction in action" (Marx 1978:185). This is not an insight to be upheld only in relation to the more abstract determinations of capitalist society, to be then dropped or somehow restricted when more concrete phenomena like power relations in commodity chains are considered.[18] The "concrete" power that each actor in a commodity chain exercises (both "power to" and "power over") is actually an expression of the "abstract" power that capital exercises over all of them.

This kind of approach does resonate with the Foucauldian view of power as ubiquitous, immanent and with the quality of a self-expanding subject (Kerr 1999:182). In this sense, it is indeed not "structurally" possessed or controlled by anybody. However, while Foucault ignored the question of the social constitution of this abstract form of power, Marx discovered its form determination as capital or self-valorising value, and the content of the latter in the alienated

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

mode of existence of the movement of human productive activity (Kerr 1999:182). Thus, although the impersonal domination of capital has no privileged locus or centre, it does have unity and determinate forms of movement or "laws" through which the former is established. The "law of value" in all its complexity captures precisely that form-determined motion of alienated human practice. In its most developed form, this "abstraction in action" achieves unity through the formation of the general rate of profit. The latter is thereby not simply an abstractly economic process determining equilibrium prices, but the form through which the formal inversion of the materiality of the powers of human activity into powers of the objectified social relation acquires its plenitude in the overall movement of social reproduction (Iñigo Carrera 1995). The changing and differentiated "concrete" power relations characterising the governance of GCCs must therefore be grasped as particular mediations in that more abstract alienated general social process of overall circulation of the total social capital, that is, as outward manifestations of the inner workings of the abstract rule of dead over living labour. Thus, they are not to be conceived of as independent, self-subsisting "factors" that externally "modify" or "influence" the operation of the law of value, as happens with all undialectical understandings of the notion of "mediation". Instead, they need to be grasped as necessary modes of motion through which the law of value is further unfolded beyond the strictly "economic" forms springing from the indirect nature of the social relations of capitalist production. In the next section, I show that it is the differentiation of individual capitals engendered by the movement of the law of value that constitutes the general determination of, and gives unity to, the formation and changing configuration of GCCs and their forms of governance. The alleged "fluidity" and "diversity" of power relations emphasised by relational approaches is actually nothing but the outward appearance of the movement of the inner contradictions of the capital form, when grasped at the level of the relations of competition between individual capitals.

Genesis, Structure and Dynamics of GCCs in the Light of the Marxian Critique of Political Economy

After what might have seemed as a long-drawn diversion, let us now sketch out the relevance of the determinations discussed above for the comprehension of the configuration and dynamics of GCCs. Behind the different particular motives usually adduced by scholars for the formation of GCCs (eg taking advantage not only of foreign cheap labour, but also of "organisational flexibility" Gereffi et al 1994:6), I think there is a more general inner content underlying this novel social phenomenon, namely, commodity chains essentially are the social form

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

through which certain normal capitals appropriate the surplus value released by small capitals.

The formation of commodity chains is therefore the concrete form taken by the competition among normal or average capitals over the extra surplus value that escapes the hands of small capitals. The deeper immanent purpose and prime mover of the outsourcing of manufacturing is therefore the multiplication of the sources of extra surplus value released by small capitals in the sphere of circulation, as particular functions of the social division of labour that were formerly done "in-house" and thereby actively participated in the tendential equalisation of the rate of profit at the general level, are now carried out outside the immediate reach of that social process. Similarly, "the contractual subordination of suppliers previously linked through 'open market' transactions" (Raikes et al 2000:396) involves the attempt by normal capitals to secure and protect the control over the outflow of surplus value released by particular small capitals. Thus, although it is true that one of the conscious motives for normal capitals to outsource manufacturing is the benefit to be obtained by the employment of "cheap labour" in low-wage locations, this line of reasoning simply assumes that those lower costs will not (entirely) translate into higher profits for contractors but will be appropriated by "lead firms". The determinations of the law of value developed in the previous section explain why this will necessarily be the case: although normal capitals are not the direct employers of those low-wage workers, they nonetheless end up appropriating part of the surplus value that corresponds to their exploitation.[19] The imposition of strict conditions for chain membership (eg the fixing of low prices for the suppliers' output) is the concrete form that mediates this transfer of surplus value from small to normal capitals. The same could be said of "organisational flexibility" which, as Raikes, Jensen and Ponte highlight, tends to be flexibility for the key agent in the chain (2000:396). From the perspective of the organic unity between the production and circulation of capital, "organisational flexibility" actually entails the optimisation of the overall turnover structure of normal capitals at the expense of higher circulation costs for all other capitals in the chain (through, for instance, accumulation of inventories or unfavourable conditions of commercial credit). More generally, the transfer of surplus value in the chain will always be mediated through the establishment of determinate conditions of turnover for each participating capital, since it is out of the whole cycle of valorisation (ie production plus circulation) that their respective concrete annual rate of profit emerges.[20]

To sum up, the geographically dispersed networks of firms that constitute GCCs are a concrete instantiation of the differentiation of capitals that mediates the establishment of the unity of social production through the formation of the general rate of profit. However, since that

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

differentiation is necessarily mediated through the concrete specific relations established in the process of exchange of commodities between determinate capitals of varying magnitudes and valorisation capacities, the indirect relations of inter-branch competition end up taking the form of their opposite: direct relations of command (or maybe co-operation, see below).

The general determination of both the composition and governance structure of GCCs also follows from the differentiation of industrial capitals outlined above. Thus, although varying in its specifics with the particularities of each GCC (which can only be captured through detailed empirical research), it seems reasonable to suggest that all commodity chains generally comprise at least three qualitatively different kinds of capitals: enhanced normal capitals, normal capitals and small capitals. The peculiarities of the governance structure will surely vary according to the composition of the chain. While relations of command/subordination will tend to prevail in nodes where exchange relations between the normal and small capitals dominate (more "captive" forms of governance), more horizontal or "co-operative" relations will tend to prevail among normal capitals and, probably, also between enhanced normal capitals and normal capitals, or between small capitals ("modular" or "relational" governance structures). The simple reason for this is that hierarchical relations are more likely to be the concrete mediating form involved in the appropriation of an extraordinary surplus value freed up by small capitals. The "lead firm" or "chain driver" in particular will most certainly be a normal capital that, on the basis of the concrete particular circumstances and industrial trajectory of each chain, has found itself in a better situation to act as the key co-ordinating agent.[21] From that position, it will therefore be able to capture the surplus profits freed by small capitals within that chain and become an enhanced normal capital, or the strongest among them if there are other normal capitals that successfully manage to make a claim over those extraordinary profits flowing out of small capitals.

Take, for example, the case of the apparel industry until the mid-1990s, one of the most extensively researched GCCs (Bair and Dussel Peters 2006; Gereffi 1999; Gereffi and Memedovic 2003) and usually taken as an emblematic case of BDCC. Simplifying slightly, there are three main players in this particular chain: "big buyers" (branded marketers, retailers and branded manufacturers), garment producers and textile manufacturers. While textile manufacturers in the United States are large firms that use highly automated labour processes (Gereffi 1994:103), garment manufacturers are small, labour-intensive factories (Gereffi 1994:102). "Big buyers", for their part, are generally capitals specialising in the design, marketing and branding of commodities and having the overall leadership in the chain. They include fashion-oriented companies, department stores, brand-named companies, mass

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

merchandisers and discount chains (Gereffi 1994:112). As Gereffi reports, developments since the 1980s meant that garment manufacturers were being "squeezed" from both ends of the apparel commodity chain by textile companies and retailers (Gereffi 1994:103). The specificities of this dynamic seem to indicate that while these two kinds of capital were normal capitals, garment producers were small capitals that released some of its potential surplus value in the sphere of circulation, which therefore became available for appropriation by the former. The role of big retailers as "chain drivers" can only mean that they were capturing the larger amount of that extraordinary surplus value through the establishment of the overall conditions of circulation of capital within the chain thereby becoming the strongest enhanced normal capital. However, the fact that textile producers were placing greater pressures on garment manufacturers for larger orders, high price of inputs and favourable payment schedules (Gereffi 1994:103), that is, shaping their turnover structure, suggests that they might have been participating in the appropriation of part of that extra surplus value as well.

However, the situation in BDCCs has more recently changed with the emergence of giant transnational contractors in East Asia. As Appelbaum (2008) shows, although this trend has been more pronounced in industries such as electronics, it has developed in the apparel and footwear sectors as well. Not only do these giant contract suppliers operate large modern factories (in contrast to the sweatshops of small contractors emblematic of the early phases of the apparel GCC), but they have also taken over many of the pre- and post-production functions previously centralised by "big buyers", including design, warehousing and control over logistics (Appelbaum 2008:73). According to Appelbaum, these dynamics seem to signal that a power shift in the apparel GCC has occurred, with the asymmetry between "big buyers" and contractors at least partly redressed (2008:71, 81). In effect, evidence seems to indicate that these giant contractors increasingly are in a better position to negotiate prices of output with giant retailers (2008:81). Interestingly, Appelbaum notes how these changes away from more "captive" governance structures comprising a highly decentralised network of small suppliers have been a largely unexpected development (2008:71). However, from the Marxian perspective outlined above, those recent transformations of BDCCs are far from unexpected and can be read as a predictable expression of the way in which the objective limits to the reproduction of small capitals (hence of more captive network forms) are reached. On the one hand, we have seen that the tendency for the concentration and centralisation of capital ultimately undermines the competitive edge of small capitals by increasing the productivity of labour of normal capitals to the point where their price of production sinks below the price that regulates the valorisation of the former. On the other hand, in light of the particular

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

characteristics of giant suppliers described by Appelbaum, it seems plausible to consider those contractors as normal capitals that, as an expression of the previous point, have eventually managed to enter into (or grow within) branches of production formerly dominated by small capitals.[22]

Thus, the insights gained through the re-framing of the particularities of each GCC in the light of the more general determinations of the differentiation of the total social capital can provide more robust general foundations for the comprehension of this concrete social form. Specifically, this framework can adjust more flexibly to some of the empirical objections to the original formulation of the general features of governance structures that have been put forward in the literature. Raikes, Jensen and Pontes (2000:397–399), for example, have disputed the idea of single chain driver (contemplating the possibility of "multi-polar driving" or of varying degrees of "drivenness" in different nodes of the chain). Ponte and Gibbon (2005:5–6) have also taken issue with the more recent five-fold typology developed by Gereffi, Humphrey and Sturgeon, claiming that the different types of governance do not necessarily reflect the overall drivenness of a chain but can exist at different nodes of the same commodity chain. These objections to the over-simplistic original portrayal of the "governance structure" of commodity chains can be easily and more rigorously addressed armed with the determinations of the differentiation of individual capitals and the release of surplus value by small capitals that I discussed earlier. "Multi-polar driving" would simply signal the presence of more than one normal capital enhancing its accumulation via the appropriation of an extra surplus value from small capitals. Similarly, the existence of varying "degrees of drivennes" or of diverse "governance modalities" in the various links of a chain, would express the fact that there are at least three qualitatively different kinds of capitals of stratified valorisation capacities (enhanced normal capitals, normal capitals and small capitals) and, above all, that the category of small capital includes a wide spectrum of concrete magnitudes and rates of valorisation. The kind of exchange relations that mediate that process of differentiation in the sphere of circulation will differ accordingly. This greater complexity of "actually existing" GCCs and their dynamics of change can therefore be grasped on the basis of rigorous and clear criteria reflecting the general qualitative determinations of the different kinds of capitals that emerge out of the system-wide laws of motion of capital accumulation. By contrast, the GCC approach can only accommodate these variations by continuous ad hoc redefinitions and refinement of previous typologies based on inductive generalisations from particular commodity chains, that is, by permanently chasing a moving target. This inability to comprehend the immanent transformative dynamics in GCCs lies, again, in the inability to connect the particular determinations of each chain

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

with the organic unity of the contradictory movement of capital as a whole through the unfolding of the law of value. As Harvey (2006:153) remarks, the organisational arrangements of capitalism are nothing but expressions of the workings of the law of value and, as such, they are more developed carriers of those very same contradictions. In this sense, it is in their nature to be subject to chronic instability and change, although always as concrete (self-negating) forms in which the general tendency for the concentration and centralization of capital ultimately asserts itself.

Conclusion

This paper has critically examined the GCC approach and the nature of GCCs. As I hope to have shown, GCC research offers a very useful empirical investigation of contemporary trends in the forms of global capitalist competition. However, it fails to root this novel phenomenon in the general laws of motion of capital as a whole. As a consequence, I have argued that the GCC approach cannot actually provide a firm explanation of the constitution and dynamics of its own object of inquiry. These shortcomings are not to be found in the more recent GCC research only, with its characteristic industrial organisation/management theory turn. It can even be traced back to its origins in the world-systems school.

Those difficulties can be overcome by re-considering GCCs in the light of the Marxian critique of political economy. The paper has shown that the latter can offer valuable insights into this social phenomenon by uncovering the way in which this industry-specific phenomenon mediates the underlying unity of the system-wide dynamics of the total social capital. To paraphrase Marx, the critique of political economy can illuminate the way in which this novel particular form taken by the competition among individual capitals across branches of production dispersed across the globe "force the inherent determinants of capital upon one another and upon themselves" (Marx 1973:651). In so doing, it can posit GCCs on more robust foundations, uncovering not only the true underlying content behind their emergence and initial configuration (the differentiation of industrial capital and the release of surplus value by small capitals in the sphere of circulation), but also the dynamic principle underlying their subsequent transformation and evolution away from more "captive governance structures" with the rise of a global supply base of giant contractors (the ways in which the tendencies for the concentration and centralisation of capital undermine the basis for the continued reproduction of small capitals).

This critical appraisal of the GCC approach has nonetheless been incomplete. For reasons of space, I have limited the discussion to the "network" aspect of GCCs at the expense of hardly addressing their global character and, therefore, their territorial dimension. This

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

latter dimension cannot be ignored when attempting to provide a comprehensive assessment of this form of capitalist competition on a world scale. In turn, this global dimension bears on the question of the contemporary forms of the international division of labour. But the determinations behind the latter cannot be grasped by simply looking at the relations of competition among individual capitals. Rather, it requires that we descend into the "hidden abode of production" to uncover the modes taken by the global extraction of relative surplus-value by the total social capital through the exploitation of the global working class.[23] And it is by considering these two aspects in their unity that the implications of this theoretical critique can be fully appreciated. Needless to say, I cannot elaborate at great length on this in these concluding remarks (see Starosta forthcoming for a more extended discussion). Still, the discussion of the "organisation fix" provided in the paper already points to some implications for the reformulation of the GCCs framework for the study of particular global industries.

So how does one translate the theoretical critique outlined in this paper into the development of a sounder empirical research on GCCs? At the merely descriptive qualitative level there is not much to be advanced beyond what GCC analysts themselves have already recognised and addressed as limitations of earlier studies utilising the framework. It is precisely at that level where the strength of the approach resides.[24] However, there are other dimensions that could still be strengthened. First, there is a need to rethink the terms for the construction of typologies. The latter should not be based on inductive generalisations out of the particular direct social relations that mediate the exchange of capitalist commodities. Instead, I think that the relevant criterion for the identification of agents and their relations essentially lies in the qualitative differentiation of individual capitals outlined above. It is this differentiation only that can shed light on the real meaning and significance of those different "explicit forms of co-ordination" in the various nodes of the chain as mediating the circulation of value along the latter.

This leads to the second point: the issue of quantitative evidence of profitability. For there is no other way of unequivocally identifying whether an individual capital is small, normal or enhanced than through a rigorous estimation of the concrete annual rate of profit (see endnote 9). This actually reflects the nature of capital itself. As qualitatively undifferentiated masses of values in process of expansion, individual capitals know no other difference than quantitative ones; or, better stated, they can only express qualitative differences through quantitative ones. Thus, the only synthetic expression of the differentiation of individual capitals lies in the concrete form taken by the degree of their valorisation capacity, that is, the annual rate of profit. In turn, this estimation can only be done on the basis of a detailed reconstruction of the specific forms taken by the turnover circuit of each capital as they flow through the different phases of their valorisation process.

A reformulated GCC empirical analysis would then consist in the reconstruction of the modalities in which the turnover circuits of the different chain participants intertwine in order to then uncover the diverse mechanisms through which some capitals transfer surplus value to others in the chain. Note, however, that this will not only be reflected in the prices at which commodities are exchanged (although that is very likely to be one of the most general and visible mechanisms), but in the establishment of all sorts of conditions that affect the circulation times and costs of each capital and, as a consequence, their respective concrete rates of profits. As mentioned above, the concrete profitability yielded by individual capitals emerges out their overall circulation process. Thus, any circumstance affecting the forms in which each capital passes through its different circulatory phases will be reflected in their profitability and accumulation capacity. These circumstances may include, among others, commercial credit conditions, differential access to financial credit, unfavourable storage costs, technology transfer royalties, specific tax credits or state subsidy schemes, and even most performance requirements for suppliers such as quality control criteria and the establishment of general standards, codes of conduct, etc. All these circumstances are bound to affect the times and costs of circulation of individual capitals, and as long as their negative effects on the unfolding of the turnover circuit are not compensated through higher prices, they entail a differentiation of concrete rates of profit. Consequently, they are all modalities of the transfer of surplus value between individual capitals in a chain that I unfolded in more abstract terms above. In this sense, the significance of the different "embedded" social relations and modes of governance established within each node should fundamentally be grasped as mediators in the uneven allocation of circulation conditions for the different participating capitals in the commodity chain. It is in relation to the intertwining of the individual turnover circuits of capitals qualitatively differentiated along the lines discussed earlier that those direct social relations matter.

A similar point could be made about the need to bring other actors into GCC analysis, a point forcefully made by many scholars both within that tradition and from related ones such as GPN research (Gibbon et al 2008; Henderson et al 2002). I could not agree more with this, although the crucial question remains as to how to conceptualise the role of those other actors in a commodity chain. Indeed, inasmuch as the turnover conditions of individual capitals are affected by a myriad of circumstances that cannot be reduced to those simply established through the action of direct members of a GCC, all actors that one way or another shape the turnover circuits of individual capitals in a chain need to be included in the picture. In this sense, it is worth

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

highlighting the crucial role of credit, both commercial and financial, in the differentiation of turnover conditions. And this means the need to pay more attention to the role of financial institutions as actors in GCCs; which, incidentally, are noticeably absent in most GCC literature.

Another of these central actors is of course the state. Yet, the significance of state policies, at least as far as the organisational dimension of GCC analysis is concerned, lies in the ways in which they mediate but, once again, do not determine, the process of differentiation of capital through which the formation of the general rate of profit asserts itself. In other words, state policies are relevant as concrete forms taken by the circulation of value along the chain. Value-as-capital is not an inert substance waiting out there to be captured by the different actors in a chain on the basis of their respective possession or exercise of power (including that to "influence" or "shape" state policy), but it is the very subject whose circulatory movement takes the form of those power relations and state policies. And it is because the overall circulation of the total social capital takes the concrete form of the differentiation of the valorisation capacities of individual capitals that state policies have a differential impact on the conditions of circulation of each kind of capital. For instance, state policies promoting the formation of university–industry research networks in the Canadian automotive industry that favour OEMs (Original Equipment Manufacturers) and large parts suppliers over so-called SMEs are not simply the (externally related) cause or consequence of the asymmetrical relations of power to "capture value" in the chain (cf Rutherford and Holmes 2008). Instead, they are the concrete mediating form that gives course and reproduces the process of differentiation of valorisation capacities objectively stemming from the unfolding of the "law of value". What would need to be investigated is the precise way in which those policies affect the turnover circuits of those capitals to see how that impact is reflected on their respective rates of profit.

Without any doubt, this reformulation of GCC research would be very laborious and would require a huge (collective) effort. In particular, the practical difficulties involved are likely to be considerable (not least in terms of availability and accessibility of relevant information). Unfortunately, it is probably the only way to go beyond the mere description of GCCs and make progress towards a real explanation and comprehension of this most salient phenomenon in the contemporary configuration of the world market which is grounded in the organic unity of the movement of the total social capital. The need for stronger theoretical foundations for empirical GCC research does not stem from an abstractly "scientific" interest but arises from what, ultimately, should guide the work of radical intellectual labourers, namely, the progressive practical transformation of the world. If GCCs matter as an object of

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

inquiry it is because their constitution and dynamics can affect our existence as social subjects in capitalism. But, more importantly, they matter because we can be active forces in their transformation through our conscious political intervention. Yet, it is only through an inquiry that goes beyond the description of the immediate appearances of social forms that we can discover the plenitude of the objective transformative potentialities immanent in them.

I would like to thank Liam Campling, Greig Charnock, Martin Hess, Juan Iñigo Carrera and three anonymous referees for helpful comments on earlier drafts of this paper. The usual caveat applies.

Endnotes

[1] For a detailed account of the evolution of the GCC approach, see Bair (2005). A more concise presentation of the current state of the art can be found in Gibbon, Bair and Ponte (2008), while the collection of essays in Bair (2009) offers a broader and more in-depth overview. In this paper I use the term GCCs as a shorthand expression that includes the more recent re-labelling of the approach as global value chains.

[2] Related approaches include international production networks (Borrus, Ernst and Haggard 2000), global production networks (GPNs) (Henderson et al 2002) and the French *filière* approach (Raikes, Jensen M F and Ponte 2000). Although originally emerging in economic sociology, the GCC approach has been widely adopted within the discipline of economic geography (Birch 2008; Hartwick 1998; Hughes 2000, 2006; Hughes and Reimer 2004; Leslie and Reimer 1999). However, given its more explicit engagement with the spatiality of globalised networks of firms, the GPNs could be said to be more influential. For detailed comparative discussions of GPNs and GCCs, see the contributions by Bair and Hesse to the recent special issue on GCCs in the journal *Economy and Society* (Bair 2008; Hess 2008). In a nutshell, two crucial differences can be identified between the GCC and GPN approaches (Coe et al 2008:272). First, the GPN approach rejects the linear conception of inter-firm relations entailed by the "chain" metaphor, trying instead to incorporate all kinds of networks configurations. Secondly, GPN research encompasses all relevant sets of actors and relationships, while GCC analysts tend to focus on the governance of inter-firm transactions only. A thorough assessment of the GPN approach exceeds the scope of this paper. However, the latter shares with GCC research the conception of the immediacy and particularity of direct social relations in production networks as exhausting the content of the phenomenon under investigation. In this sense, I believe that critique in this paper could be extended to the GPN literature as well.

[3] See Bernstein and Campling (2006a, 2006b) and Taylor (2007) for critical discussions of the GCC approach as a tool for development research from a Marxist perspective. For a non-Marxist assessment, see Dussel Peters (2008), who provides a more sympathetic but still critical appraisal of the GCC approach as a framework for the study of development.

[4] See Sturgeon (2002) on recent developments in the electronics industry that contradict that dichotomy, and Raikes, Jensen and Ponte (2000) for a general appraisal of the limits of Gereffi's original formulation.

[5] See Peck (2005) for a thorough critical assessment of the "new economic sociology".

[6] Bair (2008) argues that this recourse to network theories is more rhetorical than substantive since Gereffi, Humphrey and Sturgeon actually use a more expansive notion of network than the one derived from the new economic sociology.

[7] In the recent meso/micro turn the idea of a general economic determination of "value creation and capture" is entirely jettisoned and replaced with an account explicitly and entirely based on the pure contingency of immediate direct social relations. One could argue that this sort of analysis represents the outright capitulation before the need to give a solid foundation to the formation of GCCs based on the general "macro" dynamics of the capitalist economy.

[8] For an explicit statement of the connection between the world-systems approach and monopoly capital theory, see Hopkins (1977). In particular, Harvey rightly notes that the latter's fundamental idea that the increasing centralisation of capital with the development of capitalism leads to the moderation of competition and to the undermining of the tendency for the formation of a general rate of profit is deeply problematic. See Harvey (2006:141–144).

[9] Two points should be mentioned in relation to the question of empirical quantitative evidence of differential profitability in GCCs. First, as Raikes, Jensen and Ponte note (2000:403), despite the claims about the hierarchy of profitability along the chain, GCC analysts seldom demonstrate with rigorous quantitative empirical evidence that the profits in some parts of the chain are higher than in others. Second, the kind of quantitative evidence generally provided based on share of value added in each node of the chain (cf Kaplinsky 2000) is not a meaningful measure of each individual capital's valorisation capacity (ie their profitability), and falls into the mislabelling of the rate of profit about which Hopkins and Wallerstein (1994:18) complained in their seminal paper on commodity chains. But neither are profit margins, the measure preferred by Raikes, Jensen and Ponte (2000:403). Profit margins as a measure of the individual capital's concrete rate of valorisation obliterate the distinction between advanced and consumed capital and are therefore impotent to capture the organic unity of the rotation of capital and its effects on profitability (razor thin margins can yield a high rate of profit if compensated by a high turnover speed). The only meaningful synthetic expression of the rate of valorisation of individual capitals—and hence of their respective accumulation power—is the annual rate of profit, measured as the magnitude of appropriated surplus value in relation to the total capital advanced (different from the total capital consumed in that period). Although it certainly involves a laborious and difficult process (accessibility of information is of the essence here), it is not impossible to estimate empirically as Raike, Jensen and Ponte (2000:403) claim. See Iñigo Carrera (1998) for a model to estimate the concrete rate of profit of individual capitals based on the determinations of the turnover circuit of capital, which also develops a critique of the different mainstream attempts at measuring profitability.

[10] Here I understand the term "social capital" in the specifically Marxian sense just specified above. Thus my use of the term should not be confused with the currently fashionable concept of social capital in mainstream social sciences. See Fine (2001) for a Marxist critique of the latter.

[11] Prices of production of commodities can be resolved into cost prices (ie the cost of "inputs"—labour power and means of production, including the depreciation of fixed capital), plus the normal profits of capital (the average rate of profit on the total capital advanced for its production). See Marx (1981:257–258).

[12] One could see this as another instance of the dialectic of equalisation and differentiation that characterises capitalist production discussed by Harvey (2006:441–442) and Smith (2008:ch 4).

[13] The rate of interest will vary with the magnitude of the money capital being lent out for two major reasons. First, the rate of interest is entirely dictated by the balance of forces between supply and demand of loan capital or the competition between lenders and borrowers (Marx 1981:477, 484–489), with the force of individual lenders positively affected by the magnitude of their money capital offered on the market. Second, the

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

costs of the management of interest-bearing capital by banks proportionally decrease with the increasing magnitude of capital.

[14] This is the underlying general reason for the competitive success of the so-called "small and medium enterprises" (SMEs). See You (1995) for a general survey of small firms in conventional (both mainstream and heterodox) economic theory, whose varied explanations contrast with the one offered here.

[15] This surplus profit, it is to be emphasised, does not arise out of the active development of the productive forces of society. Quite to the contrary, it is the product of its very negation through the reproduction of small capitals.

[16] This begs the question of why this surplus profit is "retained" in those neighbouring branches of production instead of being eroded through the regular competition of normal capitals over its appropriation (thereby transferring the surplus profit over to other branches further downstream in the social division of labour until reaching individual consumption in the form of cheaper means of subsistence). However, the peculiar source of this surplus profit means that normal capitals cannot compete directly over its appropriation (Iñigo Carrera 2003:127–129). Inasmuch as this surplus profit does not derive from an increase in the productivity of labour of the early innovator but from the purchase of abnormally cheap inputs, the expansion of production resulting from the attempt by normal capitals to appropriate it would not confront any organic limit that would confine the concomitant fall of market prices to the new lower level of the aforementioned "pseudo" price of production (since that expanded output would not be regulated by changes in socially necessary labour for the production of those commodities). But this would entail a fall of the rate of profit of those normal capitals below the general level, ie their self-annihilation as normal capitals. This renders the immediate competition over this peculiar surplus profit impossible, thus blocking its transfer further downstream the division of labour. Normal capitals do compete over it but only indirectly, through the regular competition over surplus profits from innovations, which in this case includes the control of the market relation with small capitals as a "bonus prize".

[17] Here I am focusing on the determinations of the differentiation of individual capitals which are generally applicable to all kinds of commodity chains. In this sense, I am leaving aside a further differentiation of industrial capitals that springs from the more recent de-coupling between innovation and manufacturing in industries such as electronics and which has given rise to the constitution of the so-called "modular" or "turnkey" production networks (Lüthje 2002; Sturgeon 2002). As I have argued elsewhere (Starosta forthcoming), this phenomenon expresses a rather different content than the qualitative differentiation of industrial capitals stemming from the extended reproduction of small capitals.

[18] In my view, this is the tension running through Castree's attempt to marry a weak version of ANT and the Marxian critique of political economy (Castree 2002). If it is the movement of value that gives formal and substantive unity to commodity networks (2002:140), then it is not clear to me in what sense can those networks not be fully governed by the "abstraction in action" characterising the capital form (2002:139). Castree can only apparently resolve this tension by postulating an exteriority to the capital relation, a conceptual move which I see as deeply problematic, both theoretically and politically (Starosta 2004). One could argue that this recourse to a residual exteriority was already latent in Castree's idiosyncratic readings of both Postone (Castree 1999) and Harvey's earlier works (Castree 1995). These authors are interpreted as putting forward far weaker claims about capital's totalising force than, I think, they actually (and correctly) are.

[19] As Iñigo Carrera points out, despite being the ultimate beneficiaries of the "over-exploitation" of the workforce of small capitals, "lead firms" can hypocritically present

© 2010 The Author
Journal compilation © 2010 Editorial Board of *Antipode*.

themselves as the champions of the now fashionable "corporate social responsibility" (2003:63).

[20] Although not unproblematically (Gough 2004), Harvey's *Limits to Capital* has the merit of emphasising the importance of Marx's discussion the turnover of capital at a time when few scholars were engaging with Volume 2 of *Capital*.

[21] This means that there is no general formal determination that can account for the particular firm that acts as "chain driver" other than being a normal capital (when there is more than one of them in a GCC). The role of empirical research is precisely to specify that general determination for each particular chain and it is here where the GCC approach provides valuable information.

[22] Another possibility is that they are still small capitals but that the specific magnitude of money necessary to be turned into a small capital has increased as an expression of the constantly upward-moving limit for the reproduction of the lower end of the spectrum that constitutes that qualitative category. Again, only rigorous quantitative evidence of profitability can be decisive on this.

[23] For discussions of the international division of labour and commodity chains that bring the perspective of workers into the picture, see Wills and Hale (2005) and Cumbers, Nativel and Routledge (2008).

[24] See, for instance, Gibbon's (2008) refinement of the description of governance forms, entry barriers and upgrading dynamics of the clothing commodity chain.

A missing link in the Agrarian Question: the role of ground-rent and landed property in capital accumulation. The case of Argentina (1993-2019)

Abstract

This article examines the relevance of ground-rent and landed property for the economic and political forms of capital accumulation in Argentina. This specific focus on capitalist development in Argentina is more broadly framed as a theoretical intervention within recent debates on Agrarian Marxism, which addresses the major issues under controversy through the lenses of an original methodologically-minded approach to the Marxian critique of political economy. Empirical quantitative evidence for the theoretical discussion is offered through the presentation of an estimate of ground-rent and its appropriation by landowners between 1993 and 2019.

Keywords: Agrarian Marxism; Landowners; Ground-rent; Recovery of surplus value; International division of labour; Latin American capital accumulation.

Introduction

The recent special issue of JPS edited by Levien, Watts, and Hairong in 2018 (V°45, N°5-6) offered an up-to-date and wide-ranging heterodox reconstruction of "Agrarian Marxism". Indeed, the rich diversity and insightfulness contained across the articles, attests to the relevance and vitality of this theoretical program for the comprehension of the contemporary dynamics of agrarian change in the modern world system (Levien, Watts, and Yan 2018, 856). Yet, the editors themselves note that although those contributions pointed the way beyond the impasse that the old debate between Marxists and “populists” had reached, there are themes and regional perspectives which, although they should undoubtedly be part of this renewed research agenda, were not covered in the volume. Against this backdrop, the aim of this article is to contribute to this lively debate within Agrarian Marxism from two angles. First, we would like to bring to the fore what we feel were important absences in the theoretical and methodological discussion. Secondly, we intend to redress the regional imbalance by focusing on the role and dynamics of agrarian production in capitalist development in Latin America; a region which was only covered in Purcell´s (2018) thought-provoking research on cocoa production and global value chains in Ecuador.

The first two sections examine certain methodological and substantive issues which, we believe, have not been thoroughly addressed either in classical or contemporary controversies within Agrarian Marxism. In the first one, we explore the social determinations of the “peasantry” on the basis of a “systematic-dialectical” approach to the Marxian critique of political economy. This categorial re-examination of this classical agrarian question will allow us to reframe the “peasant” as a social subject fully-constituted by the unfolding of the law of value. Specifically, we argue that they are socially determined as personifications of a small capital, a category which was only hinted at by Marx in Capital, but which is crucial not only to grasp the peasantry but also to comprehend their resilience in agrarian production. In addition, an upshot of this discussion is to throw into relief the absence in most controversies of proper insight into the social determinations of modern landed property and, therefore, of landowners as a class belonging in the very nature of the capitalist mode of production.

Thus, the second section moves to the presentation of the determinations of ground-rent accruing to landowners, with a particular focus on debates over the source of surplus-value that constitutes this specific form of social wealth. The controversy over the nature and different types of ground-rent had gained prominence in the late 1970s and early 1980s, mostly among political economists and with a rather "Marxological" imprint (Ball 1977; 1980; Fine 1979; Itoh 1978). More recently, interest on this issue has resurfaced mainly among radical geographers, albeit with a focus on urban rents rather than agrarian ground-rent (cf. Manning 2021). Yet, we think that the current reconstruction of Agrarian Marxism (Bernstein 2006; Akram-Lodhi and Kay 2010a, 2010b) underestimates the significance of this social form of material wealth appropriated by landowners. In order to bring to view its contemporary relevance for the agrarian question, the discussion shall therefore look at the realisation of the determinations of ground-rent through the movement of the necessarily antagonistic relation between the personifications of capital and modern landed property.

These more abstract theoretical and methodological insights are concretised in the third section, in which we draw their implications for another longstanding debate within agrarian Marxism, namely, that of the nature of intersectoral flows of value between agriculture and industry in the capital accumulation process. More concretely, we shall examine the fundamental role of global flows of ground-rent in the constitution of the potentialities and dynamics of the specificity of capitalist development in Latin America. In this way, the article also hopes to contribute to shed light on the form in which this region of the "global south" participates in the changing forms of the international division of labour that structure the capitalist world market.

The fundamental ideas are brought together in the fourth section, which sketches out an empirical case study of the evolution of the magnitude of ground-rent appropriated by landowners in Argentina between 1993 and 2019. In the first place, this quantitative analysis should bring to light both the significance of global ground-rent flows in the highly contradictory dynamics of the accumulation process in this national space and that of the portion of social wealth that ends up in the pockets of landowners. In the second place, this quantitative analysis will allow us to address the way in which these economic determinations have been expressed in the ideological and political forms assumed by the subjectivity and action of the personifications of landed property in Argentina during the period under study.

1. The contemporary relevance of the “classic” agrarian question

In the last decades Marxist scholars seem to have reached a consensus over the resolution of the “classic” Agrarian Question, which is now considered settled and ramified into new and varied agrarian questions (Bernstein 2006; Akram-Lodhi and Kay 2010a, 2010b). Forged towards the end of the 19th century, the first version of the agrarian question centred on the “existence in the countryside of a poor country of substantive obstacles to an unleashing of the forces capable of generating economic development, both inside and outside agriculture” (Byres 1991, 9). In particular, Marxists tended to regard two related phenomena as politically significant and/or theoretically enigmatic. On the one hand, the resilience of “peasants”, which were seen as social subjects that differ from those that should express the full development of the capitalist mode of production. On the other hand, the problem of the peasants´ capacity to generate an “agrarian surplus” that could foster the industrialisation process. In sum, the classic agrarian question boiled down to the specific form of resolving the agrarian transition to a full-fledged capitalist agriculture (Byres 1996).

In broad terms, it could be argued that the varied Marxist responses to this problematic revolved around the further development or articulation of the foundational works of Kautsky (1988), Lenin (1964), Chayanov (1986) and Preobrazhensky (1965). The former two authors had highlighted the existence of inherited historical barriers to the entry of capitalist firms in agrarian production, which should eventually vanish with the evolution and consolidation of capitalism. Chayanov, by contrast, had stressed the existence of a specific mode of production or set of social relations that characterised the agrarian sector, which would thereby not necessarily tend to disappear as capitalism developed. Lastly, Preobrazhensky oriented his analysis to the role of peasants in the industrialisation process, focusing on the intersectoral flows of value between agriculture and industry.

In more recent times, these different responses have seen a wider and deeper integration, thus leaving behind the apparent opposition among the various traditional approaches, particularly with respect to the notion of the peasant as a social subject who did not belong in the essential character of the capitalist mode of production (Bernstein 1986; Gibbon and Neocosmos 1985). Bernstein´s (1988) pioneering approach probably is one of the most elaborate in this regard. In his view, the peasant must be explained as a social subject "exclusively constituted […] through the basic social relations and dynamics of the capitalist mode of production" (Bernstein 1988, 259), and must be grasped through the specifically-capitalist category of the "petty commodity producer". Moreover, Bernstein added, the "spaces" or "places" for petty commodity production "within the social division of labour are continuously created as effects of the law of value in capitalist competition, accumulation, and concentration" (Bernstein 1986, 18–19) and, consequently, "petty commodity production will exist as long as capitalism exists" (Bernstein 1986, 25). However, rather than systematically unfolding the "form-determinations" of competition, accumulation and the concentration of capital that engender petty commodity production, Bernstein just pointed to a set of external circumstances, such as "conditions of access to key resources", the configuration of "markets", "nature" and "government policies", among others (Bernstein 1994, 56). In other words, according to this approach, the limits and potentialities of petty commodity production cannot be immanently derived from the general determinations of the "laws of movement of capital". Instead, Bernstein considered that this phenomenon can only be examined at a very concrete level of research, since at stake are processes which "are always the effect of particular conditions of competition and class struggle requiring concrete investigation" (Bernstein 1988, 264).

Thus, in both the classic controversies and their more recent reception, the agrarian question was essentially conceived of as a problematic of historical transition between modes of production or more narrowly focused on the problematic of the persistence of the peasantry. Either way, the capitalistic social determinations of landowners as a class have remained for the most part overlooked.[1] In this context, it comes as no surprise that the specificity of modern landed property in agrarian production, its relationship with capital and its "laws of motion" and, therefore, the existence of surplus profits appropriated in the form of ground rent have become increasingly neglected in the specialised literature of Agrarian Marxism. To put it differently, all discussion of landed property has been consigned to its role as historical premise or presupposition of the emergence of the capitalist mode of production. But very little light has been shed on its determination as a posited result of the reproduction of capital.

---

[1] For a similar conclusion from a different theoretical perspective, see Carlson (2018) and Manning (2020).

Bernstein´s retrospective look in the 1990s on the resolution of the classic agrarian question is quite telling in this regard: “the land question […] was resolved either by revolutionary means, by bourgeois land reforms, or by the internal transformation of feudal property to capitalist farming” (Bernstein 1991, 487). In this way, all contemporary relevance of the role of landed property in agriculture tends to become boiled down to a problem of access to land for subsistence production or, as Araghi puts it, to a matter of “dispossession through displacement” (Araghi 2000). The essential difference between capital and landed property has been therefore progressively left out of the picture. Similarly, one could argue that to the extent that the industrialisation process gradually left its initial stages behind, Agrarian Marxism also tended to lose interest in the problematic of intersectoral transfers of value between agriculture and the rest of the economy. As Akram-Lodhi and Kay succinctly and expressively conclude, with “the development of the forces of production on a global scale […] agriculture has effectively become ‘decoupled’ from the process of capital accumulation” (Akram-Lodhi and Kay 2010b, 264).

In sum, considering this intellectual trajectory traversed by Agrarian Marxism, it is not surprising that the classic agrarian question has been declared fundamentally settled in the face of the development of capitalism in the past century, particularly in the light of the increasingly manifest subsumption of different agrarian productions to the movement of "Transnational Corporations" associated with the phenomenon of so-called globalisation. Yet, we think that the matter looks different when the agrarian question is approached through the systematic exposition of the general determinations of capital unfolded in the Marxian critique of political economy.

As discussed at great length elsewhere (Starosta 2015), and as has been ever more widely acknowledged in the Marxist literature (Postone 1993), one of the most potent scientific discoveries of Marx's critique of political economy was that capital is neither simply a thing (for example, the instruments of production), nor a productive unit or legal entity (such as a firm), nor a social grouping sharing common characteristics and interests (for instance, business or the bourgeoisie). In its general determination as self-valorising value, capital is actually a materialised social relation between commodity owners differentiated into social classes, which, in its fully developed form as the total social capital, becomes inverted into the alienated subject of the unity of the process of social reproduction and its expansion. Thus, capital is essentially the movement of self-expansion of the objectified general social relation between private and independent human beings which, in its own process, produces and reproduces the latter as members of antagonistic social classes (Marx 1976, 723–24; 1992, 185). All moments of the human life process thus become inverted into material bearers of the life cycle of capital, or they become forms assumed by the flow of value in its circulatory process. Subsumed under the capital-form, the alienated content of social life becomes the production of surplus value or the formally boundless quantitative progression of the general reified form of social mediation (Marx 1976, 251–57).

From this standpoint, every privately-organised productive unit, as a materially integral part of the social division of labour, becomes necessarily subsumed under the movement of formation of the general rate of profit. It follows from this that, whether they have the phenomenal form of an individual capital or not, all productive units become formally determined as if they were one. Hence, the human individuals whose reproduction process is subsumed to that private fragment of social labour, become invested as personifications of capital, labour power and, eventually, landed property. Seen in this light, the peasant is an individual who is simply characterised by the concentration in their own subjectivity of the personification of those three different and antagonistic social roles (Marx 1988, 556; 1994, 142).

This approach to the social determinations of the peasant reframes the discussion of the characterisation and historical potentialities of the peasantry in relation to the kind of capital they personify and the relation that they have in that capacity with landed property. However, in the systematic exposition of the critique of political economy, Marx never went beyond the simplest determination of individual capitals as formally undifferentiated organs of the total social capital. Presumably, he had planned to defer the treatment of the differentiation of individual capitals (in particular, that between normal and small capitals) to the separate book on the concrete forms of competition that he eventually never managed to complete during his lifetime (Marx 1988, 444). Yet, as Starosta (2010) argued building on Iñigo Carrera´s (2016) insights, it was precisely in considering peasant agricultural production as the carrier of the determination of a small capital that Marx hinted at the basic elements for such a systematic exposition of the differentiation between capitals.

In a nutshell, in those pages Marx implies that despite its significantly smaller scale, the individual capital which the peasant personifies can survive competition from normal capitals. This is possible because “the smallholding peasant´s exploitation is not limited by the average profit on capital, in as much as he is a small capitalist; nor by the need for rent, in as much as he is a landowner” (Marx 1991, 941). Therefore, the smallholding´s higher costs could be offset by having “the absolute limit” to its reproduction in “the wage that he pays himself, after deducting his actual expenses” (941–42). In other words, this absolute limit implies the absence of all profitability as personification of capital and an income which boils down to the peasant´s condition as personification of labour. As argued elsewhere (Starosta 2010; Iñigo Carrera 2016), before reaching this extreme limit, the small agrarian capital does yield positive profitability, which is regulated by the rate of interest on the liquidation value of productive assets. Against this backdrop, the limit selling price which secures the small capital´s reproduction could even stand below that of the regulating price of production of normal capitals. Under those circumstances, the peasant´s small capital would outcompete normal capitals, with the result that a portion of the surplus labour performed there would be “presented to society for nothing” (Marx 1991, 942).

Now, the specialised literature in agrarian studies has broadly acknowledged and thematised the existence of specific obstacles for the valorisation of capital in agriculture, among which the limits to territorial expansion, climate-induced pronounced fluctuations of the productivity of labour and overly long production periods stand out (Bernstein 1994, 50–52). These barriers have so far made agriculture particularly apt for the prevalence or even full dominance by small capitals. By contrast, those normal capitals which operate in neighbouring branches of production, which provide agriculture with means of production or commercialise agrarian commodities, have shown virtually no interest in embarking on a process of vertical integration of agricultural production (Heffernan 2000, 68–71). Instead, they have preferred to "double squeeze" the latter by forcing high prices for agricultural inputs or low prices for agricultural output (Weis 2007, 82). Seen in this light, the displacement of the peasant or petty commodity producer by capitalist firms, or a changed orientation of production to the world market are far from entailing the overcoming of the "agrarian question". As long as agricultural capitalist enterprises continue to be small capitals, the limits to the development of the productive powers of social labour in agriculture will remain firmly in place.

On the other hand, the "colonisation" of agrarian production by small capitals leads to a particular relationship between capital and landed property. In principle, there should be a tendency for the repulsion and separation between them. The reason for this is that capital invested in the acquisition of land yields the rate of interest only (Marx 1991, 760–61), whilst its valorisation in production yields the average rate of profit, which is, by definition, normally higher (480–82). By contrast, by virtue of the significantly lower-than-average rate which regulates the valorisation of small capitals, they are unaffected by this barrier to land ownership; it is a matter of indifference to them whether to invest additional capital in buying land or in the expansion of the scale of production. Hence the observable empirical tendency in agriculture for a tenancy regime which fuses together capital and landed property.

The American "farmer" probably is the classic figure that incarnates this "hybrid" personification of reified social relations. However, of more immediate relevance for the theme of this article, it also is the case of the so-called "agrarian producer" (or "chacarero") from the Argentine Pampas. This is a social subject whose reproduction is subsumed under the law that governs the subsistence of small capitals as just sketched out. Consequently, they act in the social reproduction process not only as their own labourer for a wage-equivalent, but also totally or in part as their own landowner. Hence the active role of this type of individual as the political subject *par excellence* in social conflicts over the appropriation of ground-rent, as we shall see in our empirical discussion in a subsequent section.

At this juncture, it might be worth noting that the joint personification of capital, wage-labour and landed property is not exclusive to the case of "farmers" and "chacareros", who can be seen as the "genuine" expression of the small agrarian capital. This three-fold personification also tends to be the social determination of individuals that the capital accumulation process throws into the ranks of the rural relative surplus population. In effect, to the extent that their "income" sinks *below* the absolute limit to the subsistence of small capitals (i.e. below the equivalent of a "normal" agrarian wage), the law that comes to regulate the reproduction of this private fragment of social labour (hence of the individuals who personify it), no longer is the formation of the general rate of profit. Instead, their material and social reproduction becomes subsumed under the accumulation dynamics which determine the respective volume of the different forms of existence of the relative surplus population. A paradigmatic example is that of the great majority of peasant communities in most of Latin America, whose subsistence in impoverished conditions rests on petty commodity production usually catering for local food markets, but which have more recently managed to act as suppliers in "global value chains" (e.g. those cocoa "owner-producers" in Ecuador barely scraping a living on USD 2 a day, which Purcell (2018) discusses in great depth in the recent special issue on Agrarian Marxism in journal). In this latter case, the subjective aim of these individuals centers exclusively on their most immediate material reproduction as personifications of labour, and they are therefore entirely indifferent to the fluctuating movements of ground-rent.[3]

In our view, this unified concrete mode of existence of capital and landed property explains, to a large extent, the aforementioned neglect of the contemporary role of modern landed property in agricultural production within Agrarian Marxism. However, when the reproduction of the peasantry is approached as a concrete outcome of the unfolding of the "law of value" as mediated by landed property, the latter´s specific significance for agrarian production comes to the fore. As we shall see later, this is also relevant with regards to the problematic of intersectoral flows of value between agriculture and industry, which has been another longstanding concern of the first controversies within Agrarian Marxism. From both angles, the implication of our argument so far is that the consideration of the classic agrarian as fully resolved might be too hasty. To further substantiate this conclusion, we must turn now to the closer examination of the nature and source of capitalist social wealth that takes the form of ground rent.

---

[3] For this reason, we shall leave them out of the main theme under discussion in this article. See Villar (2022), for an in-depth examination of the stark contrast between these two qualitatively different kinds of "hybrid" personification ("genuine" small capitals vis-à-vis the rural surplus population) in the case of Paraguay.

2. Ground rent and its source

Ground rent appears as a mass of value which ends up in the hands of landowners exclusively by virtue of their ownership of land. In his systematic-dialectical exposition of this form of surplus value, Marx identified four mechanisms through which landowners manage to capture this portion of social wealth: differential rent I, differential rent II, absolute rent and simple monopoly rent. The common basis of all of them resides in the existence of natural conditions of production materially tied to land, which thereby have a quantitatively limited availability and which capital cannot reproduce without affecting its normal valorisation.

In the case of both types of differential ground rent, they are constituted by surplus profits that emerge as a result of differences in the productivity of labour which, in turn, derive from capital investments in natural environments with diverse material properties, fundamentally fertility or location. Differential rent I simply derives from the varying productivity of labour set into motion by capitals invested on plots of land with distinct degrees of fertility or proximity to consumer markets (Marx 1991, 779 ff). By contrast, albeit predicated on the existence of type I, differential rent II stems from the varying productivity of labour borne by successive capital investments on the same plot of land (812 ff). In both cases, the limit to the extensive or intensive application of capital is reached with the last investment that yields the average rate of profit (i.e. allows the normal valorisation of capital), given the market price for the respective commodity as determined by effective demand.

For its part, absolute rent is constituted through the appropriation of the surplus profit that emerges from the difference between the value and the price of production of commodities, which in turn results when the active affirmation of the landowners´

absolute monopoly over that natural condition of production hinders the participation of agrarian capital in the formation of the general rate of profit (882 ff). Lastly, simple monopoly rent derives from the sheer existence of private property over the worst land (898; 906; 910). Insofar as these two types of ground rent entail a higher unit price for agricultural produce, they also affect the magnitude of differential ground rents (897).

The identification and explanation of the various mechanisms through which surplus profits in agricultural production are transformed into ground rent have been subject to wide ranging controversies in the specialised Marxist literature. In the first place, scholars have debated the determination of absolute ground rent vis-à-vis that of simple monopoly rent (Bortkiewicz 1910; Emmanuel 1972, 216–23; Harvey 2009, 179–82). In the second place, in the last quarter of the 20th century a controversy over the characterisation of differential rent II cropped up (Ball 1977; 1980; Fine 1979; Flichman 1977). Lastly and of more direct relevance for the theme of this article, there has been a polemic on the primordial source of the surplus value which takes the form of ground rent. More specifically, at stake here is the identification of the wage workers who produce the surplus value that landowners appropriate as the revenue accruing to landed property. As we shall see, this point is of fundamental significance not only with regards to the role of agrarian production in capitalist development as debated in the "classic" agrarian question, but also in connection with the specificity of Latin American societies in the global unity of the accumulation of capital. Let us therefore examine this latter controversy in more detail.

In essence, two main perspectives can be discerned. On the one hand, there are those scholars who maintain that, regardless of the type of ground rent, in all cases it is constituted by surplus value produced within agriculture. On the other hand, other authors argue that, except for absolute rent, all other forms of ground rent have their source in surplus value originally produced outside agrarian production.

The former perspective has been fundamentally developed by the Soviet orthodoxy that consolidated out of the debate tiggered by Preobrazhensky´s (1965) work on the role of the agricultural sector in the industrialisation process (Lapidus and Ostrovitianov 1929, 279–80; Lyubimov 1930, 118–19; 211–18; 223–25; 247–74; Institute of Economics of the Academy of Sciences of the U.S.S.R. 1957, 222–23). The basic argument that crystallised as official doctrine was that insofar as ground rent originates due to the higher productivity of labour which produces in more favourable circumstances, the substance of surplus value that constitutes ground rent must be found in that labour itself. This is the conclusion drawn by, for instance, Lapidus and Ostrovityanov: "ground rent, which constitutes an extra profit over and above the average profit, is created by the higher productivity of the workers employed on better soil" (Lapidus and Ostrovitianov 1929, 279). More sophisticated contemporary versions of essentially the same longstanding argument (Balardini 2017) emphasise that since value is a reified social relation, its magnitude can only be determined in the exchange process. Consequently, these authors reject the notion that there could be such thing as intersectoral transfers of previously-constituted masses of value.

However, a first problem with this line of reasoning is that it stands in blatant contradiction with the Marxian explanation according to which an increase in the productivity of labour leads to a larger quantity of use values produced in a certain time but leaves unaltered the total amount of value (Marx 1976, 130–31). Furthermore, as pointed out by some scholars in other debates which have also touched upon the problematic of value-transfers, the implication of the idea that ground rent is constituted by the surplus labour extracted from agricultural labourers is that the total quantity of surplus value generated across society would no longer coincide with the total quantity of surplus labour performed by the working class as a whole. The immanent unity between materiality and social form characterising capitalist society would thereby be torn asunder (Mandel 1998, 92–107; Starosta, Caligaris, and Fitzsimons 2021).

The other position in this debate initially developed within Japanese Marxism in response to Lyubimov (1930) and was also put forward by several Latin American contributions to debates over dependency and the agrarian question in the region around the 1970s (Sakisaka 1930; citaddo en Itoh, 1988; Uno 1977, 98 fn 4; Itoh 1988, 237 ff; Laclau 1969; Bartra 1979). The central argument was that since in agriculture the market price is regulated by the least favourable conditions of production, those privately-performed fragments of social labour which set into motion a higher productivity are also expressed in that market price. And this leads to a quantitative divergence between the latter and the magnitude of value of agricultural commodities. As buyers of the consequently dearer agricultural produce mostly comprise members of the working class, the mass of value at stake entails a deduction of the surplus value that could otherwise be extracted from them should they need not consume those higher priced commodities. It follows from this that the surplus value which constitutes ground rent originates in those branches of production in which the said wage workers/consumers are employed (i.e exploited by capital).

In our view, this latter perspective is the one which is consistent with the substantive and methodological foundations of the Marxian critique of political economy. As a matter of fact, it is in line with Marx´s own argument in his examination of ground rent which leads him to characterise this part of surplus value as a “false social value”, which “results from the law of market value to which agricultural products are subjected” (Marx 1991, 799).

This conclusion that ground rent is surplus value produced in other branches of the social division of labour allows to cast in a different light both the parasitical character of the landowning class and the potential flow of the so-called “agrarian surplus” to industrial capital in general. In the first place, it shows that the material and social reproduction of landowners, as the class of personifications of landed property, and regardless of whether it concretely exists in unity with, or differentiated from, the class of agrarian capitalists, comes at the expense of the accumulation of capital as a whole. More specifically, surplus value that could feed the expansion of social production ends up being squandered in a social class which plays no active part in the capitalist organisation of social labour (not even that of exploiting the “direct producers” of surplus value). In the second place, and fundamentally, it becomes clear that the part of agrarian social wealth transferred to industrial capital in general, far from involving a primordial drain out of agrarian production, actually entails the recovery of surplus value which had originally slipped from industrial capital´s hands. Let us scrutinise this latter point more closely.

First of all, the possibility of the recovery of surplus value initially pocketed by landowners lies in the nature of the revenue that constitutes ground-rent. This form of revenue reproduces a social subject that plays no role in the immediate process of production, so that the appropriation of that part of the revenue by third parties does not affect the reproduction process in its unity (Marx 1988, 539).

From this viewpoint, it would seem that the total social capital has no choice but to get rid of the landowning class, taking directly into its hands the exercise of monopoly over the land, or rather, converting private property of the land into state property, so as to not have to cede to this parasitical class a part of the surplus value generated by its own workers (Marx 1988, 470).

However, the abolition of private property for a means of production as significant as the land cannot be realised without calling into question the private property for the rest of the means of production and private property in general. Thus considered, it would appear that the total social capital has no option but to live with the landowning class and, therefore, to cede to it all surplus value corresponding to the form of ground-rent (Marx 1988, 278).

The recovery by the total social capital of the surplus value produced by its workers but which ends up in the hands of landlords in the form of ground rent contains, then, a contradiction. On the one hand, a recovery could be possible insofar as landlords are mere social parasites and, therefore, useless for the entire process of the accumulation of capital; on the other hand, doing away with landlords would imply jeopardising private property of the land and, along with it, the very process of capital accumulation. Marx presents the development of his contradiction in the following way: "Capital cannot abolish landed property. But by converting it into rent [which is paid to the State] the capitalists as a *class* appropriate it and use it to defray their State expenses" (Marx 1988, 470).

In summary, insofar as ground rent is a mass of value that the landlord appropriates only by virtue of the economic relation they personify, the total social capital can appropriate from them through the power of the state (in its capacity as the political form of capital in general; Müller & Neusüss, 1975; Starosta, 2015). However, precisely because ground rent is revenue accruing to the private property of land, this appropriation is quantitatively limited by the very questioning of private property that it entails.

3. The agrarian sector and the industrialization process

Although seldom explicitly acknowledged or formulated in the substantive terms outlined in the previous section, the contradiction between capital (rate of profit) and landed property (ground-rent) has arguably underpinned another issue which has caught the attention of Agrarian Marxism beyond the classical concern over the "capitalization of agriculture", namely: the broader question of the relationship between the agricultural sector and capital accumulation and, more concretely, that of the role of the so-called "agrarian surplus" in financing the "development project" (Akram-Lodhi and Kay 2010a, 192–93). The intellectual lineage of this theoretical concern can be traced back to Preobrazhensky´s intervention in the debates over the New Economic Policy in the Soviet Union (1965, 194–95). However, the part played by "intersectoral transfers" between agriculture and industry was later reconsidered in wider terms as a central aspect of the political economy of "late industrialization". Specifically, the issue has emerged in comparative studies of capitalist development in Latin America and East Asia.

In effect, some scholars have maintained that the early implementation of comprehensive land reforms prior to the industrialization process, coupled with the subsequent agrarian state policies channelling the intersectoral transfer of resources, have been a central determinant of East Asia's (mainly, Taiwan's and South Korea's) outperformance of Latin America (Anglade and Fortin 1990; Kay 2002; Kohli 2004). Thus, the argument goes, whilst South Korean and Taiwanese states were able to finance the industrialization process through ‘the squeeze of the peasantry’ upon the abolition of landlordism, the failure or lateness of land reforms in Latin America resulted in the continued reproduction of a politically powerful landlord class which hindered the state´s attempt to “extract such a high surplus from agriculture as in South Korea and Taiwan” (Kay 2002, 1093). However, as argued at greater length elsewhere (Grinberg and Starosta 2009), although agrarian policies have indeed been a significant element in each region´s respective processes of capital accumulation, the differential resolution of the “agrarian transition” has not been a fundamental reason behind the divergent paths of industrialization. Instead, those distinct political forms have expressed the qualitatively different modes taken by the essentially global process of capital accumulation in each region, which in turn have mediated the unfolding of the changing historical modalities of the capitalistic international division of labour (Charnock and Starosta 2016). More specifically for the theme of this article, we shall see that the existence of a global inflow of extraordinarily large masses of social wealth in the form of differential ground-rent into Latin America, implied that capital so far has not confronted established forms of landed property as an immediate insurmountable barrier for its accumulation. Consequently, it has been able to valorise normally (i.e. at the average world market rate of profit) by appropriating only a portion of ground-rent and, hence, through the continued reproduction of landlords as a class. However, we shall also see that this form of capital accumulation has resulted in increasingly limited developmental potentialities for those national territories.

Now, as is recognised by virtually all accounts of the history of capitalist development in Latin America, the original subsumption of these territories to the global accumulation of capital was based on the production of agricultural and/or mining commodities for the world market. As Marx remarks in *Capital*, the establishment of this "classic" modality of the international division of labour (that he labels "new"), which "converts one part of the globe into a chiefly agricultural field of production for supplying the other part, which remains a pre-eminently industrial field" (Marx 1976, 580), was determined by the production of relative surplus value through the system of machinery of large-scale industry.

In effect, the exceptional natural conditions prevailing in many of these territories allowed for a greater productivity of agricultural or mining labour, thereby resulting in the cheapening of means of subsistence and a lower value of labour-power. However, this form of subsumption of Latin American territories into the global circuits of accumulation was ridden with a contradiction: if, on the one hand, the total social capital enhanced its valorisation by reducing the value of labour-power, on the other this was partly offset by the drain of surplus value, otherwise available for capital's appropriation, flowing into the pockets of domestic landowners in the form of ground rent. Moreover, to the extent that primary commodities produced in the region have been exported and consumed overseas, ground rent has constituted a continuous extraordinary international inflow of social wealth (as opposed to the normal outflows in the process of equalisation of the worldwide rate of profit emphasised by some Marxist dependentistas, e.g. Dussel, 2002).

Capital was thus driven to overcome this barrier to its accumulation capacity by reshaping those spaces of valorisation in order to recover part of that surplus value, through the establishment of an "antagonistic association" with local landowners over the appropriation of ground rent. From being simply a source of cheap raw materials and means of subsistence, those territories became also determined as sources of ground rent recovery for global industrial capital. The developmental trajectory of these countries has been determined by the historical course of this modality of capital accumulation, not only throughout the so-called agro-export stage, but also during the so-called Import Substituting Industrialisation (ISI) phase and, in South America, until contemporary times (Iñigo Carrera 2016, 34–47).

As Caligaris (2016, 66) points out, insofar as "the political representation of the global total social capital by the state is mediated by the national form taken by the accumulation process" the total social capital's recovery of ground rent "must take shape, first of all, in the appropriation of ground-rent by the national total social capital of "resource rich" countries through its own national state." This political mediation has been necessary in order to block the "spontaneous" course of ground rent towards landowners through a wide array of state policies that intervene in the circulation of ground rent-bearing commodities and divert its flow towards industrial capital. Thus, the transfer of ground-rent has been achieved through different policy mechanisms (overvalued exchange rates, export and import taxes, direct state regulation of staple food and raw material prices, etc.), which resulted in the establishment of specific domestic conditions for the circulation of capital within those national territories. Consequently, its appropriation could only be done by industrial capitals operating within those countries and whose circuit realised its final phase (i.e. the sale of commodities) almost exclusively on protected domestic markets of a very limited size vis-à-vis world market norms (Grinberg and Starosta 2009, 769 ff). Although this has meant that individual capitals could not reach the scale needed for profitably utilising advanced technologies, they have compensated for the resulting higher production costs by appropriating a portion of ground-rent. In this way, they have valorised at the average rate of profit despite their restricted magnitude and backward technologies. This abundant extraordinary mass of social wealth has systematically complemented the surplus-value extracted from the domestic working class to the point of marking the very specificity of the accumulation process in those national spaces.

The modality of the accumulation of capital based on the appropriation of ground-rent in Latin American protected markets has been very attractive for domestic capitals which, with the exception of those producing ground-rent-bearing commodities, were not competitive enough to sustain their expanded reproduction by producing for the world market. But additionally and fundamentally, those markets have proved especially profitable for industrial capitals of foreign origin (i.e. TNCs), which were established there from the mid-to-late-1950s onwards. Unlike the internationalisation strategy of TNCs in East Asia (the establishment of "world market" factories, whether directly or through OEM arrangements), foreign capitals in Latin America operated on the smaller scale that those domestic markets required and, given their protected nature, actually made possible. In this way, TNCs in Latin America managed to valorise obsolete fixed capital and accumulate without spending a portion of surplus value in the active development of the productive forces of social labour. However, the other side of this same coin is that the scale of Latin American processes of capital accumulation continued to be structurally dependent on the highly-cyclical evolution of the magnitude of ground-rent available for appropriation (hence the widespread "political and institutional instability" that has historically characterised most Latin American countries, with sharp oscillations between nationalistic populist and/or developmentalist regimes and neo-liberal ones).

This also explains the noticeable lack of dynamism of capital accumulation in the region since the mid-to-late-1970s, which was momentarily and only partially reversed during the recent "primary commodities boom" that seems to be just coming to an end (politically expressed in the current shift to the right in, for instance, Argentina, Brazil and Chile):[4] in effect, the mass of ground-rent, especially of agrarian origin, has been, on average, growing at a slower pace than is required by industrial capital in Latin American national spaces of accumulation. As a consequence, the process of capital accumulation in the Latin American countries slowed down or entered into deep crisis. In this context, and in order to compensate for the slowly growing ground-rent in sustaining industrial capital's profitability, these national processes of capital accumulation have resorted to other sources of extraordinary social wealth, such as the payment of labour-power below its value and the massive inflow of global fictitious capital in the form of mounting foreign debts (the latter made available as a result of the expansion of international liquidity deriving from the long-standing crisis of global overproduction).

Now, since at least the late 1950s, the planetary production of relative surplus value by the total social capital has led to the emergence and gradual development and expansion of a novel configuration of the international division of labour, which has not simply displaced but co-exists alongside the "classic" modality just sketched out. Premised on the concrete material forms taken by the further automation of the capitalist labour process and advances in means of transport and communication, the so-called "New International Division of Labour" (NIDL) has revolved around the international fragmentation of the collective productive subjectivity of the working class (Fröbel, Heinrichs, and Kreye 1980; Iñigo Carrera 2014, 560–65; Starosta 2016, 84–96). Moreover, as a result of its own immanent tendencies, the simplest original form of the NIDL has evolved into a more complex constellation, whereby capital searches worldwide for the most profitable combinations of relative cost and qualities/disciplines resulting from the variegated past histories of the different national fragments of the working class. Each national sphere of accumulation that actively participates in the NIDL therefore tends to concentrate on a certain type of labour-power of distinctive "material and moral" productive attributes of a determinate complexity. While spatially dispersed from each other, they are all collectively exploited by capital as a whole in the least costly possible manner.

---

[4] For the so-called "Pink Tide" in South America, see Grinberg and Starosta (2015) for Argentina and Brazil, and Purcell (2016) and Dachevsky and Kornblihtt (2016), for Ecuador and Venezuela.

Although this more recent global restructuring of the international of labour had its most emblematic expression in the "late industrialisation" experience of East Asia since the 1960s (Grinberg 2016), it also had a profound impact in Latin America; paradigmatically in Mexico after the "debt crisis" of the early 1980s and, more recently, in Central America and the Caribbean Basin. Thus, despite the similar developmental trajectory of Mexico vis-à-vis Argentina and Brazil until the 1980s, in the past three decades the former country has transformed the specificity of its capital accumulation process. More concretely, it has become a source of relatively cheap and disciplined simple labour power for industrial capital in general, which exploits it in the material conditions (of scale and technology) needed for competitive world market production (whether directly in Mexico through the maquilas regime, or mediatedly through the international migration of workers into the USA). Hence the contrast with Argentina and Brazil, where capital continued to find it more profitable to valorise on the basis of the appropriation of a portion of ground-rent; either because the specific kind of labour-power it needed was not there or was not cheap enough, and/or because the mass of ground-rent was large enough to offset the benefits of a "structural transformation" in the other direction by providing the source of extraordinary social wealth sustaining those profitable protected domestic markets (albeit on a diminishing scale).

In the following section, and by way of empirical illustration of our general argument, we shall provide quantitative evidence for Argentina of what could be referred to as the "social cost of reproduction of the landowning class". On the one hand, we shall see that, in effect, in the last 30 years landowners have appropriated a significant amount of social wealth: they have pocketed an average of 30% of the total ground rent that has flowed into the country. On the other hand, this means that this has not prevented capital from recovering the remaining 70%, thus making evident that the antagonistic relationship between capital in general and landed property has continued finding "room to move" in Argentina through the reproduction of landowners as a class.[5]

---

[5] Our discussion will focus on the portion of ground rent appropriated by landowners. We are currently finalising an update of the measurement of the ground rent appropriated by capital in general.

4: The evolution of the magnitude of ground rent appropriated by landowners and its concrete political forms: the case of Argentina 1993-2019.

To begin with, let us draw the reader´s attention to the fact that, in Argentina, there is a noticeable prevalence of small capitals in the agrarian sector, just as discussed in section 1. Consequently, the tendency for the unity between capital and landed property is also verified, with the same individual thereby determined as a joint personification of both social roles. In effect, according to the latest National Agrarian Census (2018), as many as 47276 holdings explain the total annual crops in the Pampas. In turn the tenancy regime in the Pampas is still dominated by the individual agrarian capital´s ownership of land: whilst this latter form of land tenure accounts for 61% of the cultivated area, only 36% takes the form of tenant farming.[6] Admittedly, the share of lands under tenancy has risen, albeit with fluctuations, over the recent past. In our view, however, this empirical trend does not clash with the general determination on the unity between capital and landed property in agrarian production discussed in section 1. As a matter of fact, it is a phenomenon to be expected in circumstances of pronounced technological change, as happened between the late 1990s and the mid-2000s. In effect, the resulting increase in minimum "efficient" scales of production led to the ruin of smaller agricultural holdings. Consequently, those areas came to be leased to neighbouring farms, which thereby extended their scale of operation, or to so-called "large sowing pools". The latter surged during the unprecedented hike in prices in the 2000s and were mostly formed out of speculative capitals from outside agriculture through, for instance, the establishment of financial trusts (Fernández 2010; Caligaris 2015). Yet, they tended to disappear when agrarian prices eventually dropped towards the mid-2010s (Gras and Cáceres 2017). Either way, these phenomena led to the diffusion of a novel kind of social subject, namely: the "pure" *small landowner* (so-called "mini-rentier" in the local literature), whose subsistence turns to rest on the minimum magnitude of ground-rent necessary for their material and social reproduction, which in turn can be comprised by familial subdivision of landed property through inheritance.[7] Against this backdrop, hereafter we shall refer to "landowners" to denote all social subjects whose material reproduction is tied to the personification of landed property, whether "in pure shape" or jointly as personification of an agrarian capital as well.

---

[6] For an in-depth analysis of the latest National Agrarian Census, see Ameghino and Fernández (Ameghino and Fernández 2019).

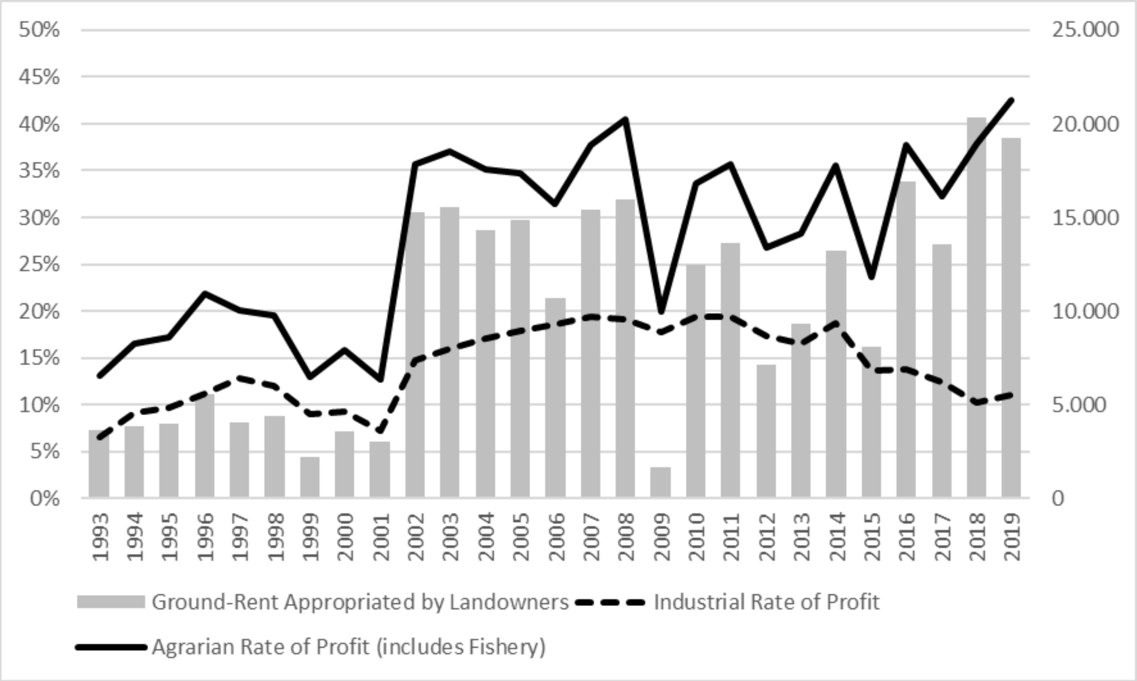
Our quantitative estimate of the magnitude of ground-rent captured by landowners draws on the general methodology originally formulated by Iñigo Carrera (2007), which he applied to the period 1882-2004. Here we present a new estimate which involved a revision of some statistical sources and the update of all data, covering the period 1993-2019. In a nutshell, the method consists in the estimation of both the primary appropriation of ground-rent by landowners and the portion recaptured by capital in general. In this article, we focus on the former portion, which derives from the comparison between the rate of profit in the agrarian sector with that in industry, with the latter as a proxy for the normal or general profitability of capital within the national space.

---

[7] In our view, these two phenomena (the leap in the normal degree of concentration of capital in agrarian production and the appearance of sowing pools) underlie the so-called fading away of the "chacareros world" described in the specialised literature (e. g. Balsa 2006; Gras and Hernández 2019).

Insofar as the rate of profit in both sectors is calculated as the relationship between the surplus value appropriated and the total capital advanced, a higher sectoral rate of profit in agriculture entails the existence of surplus profits in that branch of production. As we have seen in section 2, this mass of capitalist social wealth is transformed into ground-rent accruing to landed property. To put it differently, the inter-branch comparison of rates of profit allows to set apart the profit of agrarian capital and landowner´s ground-rent. This is shown in figure 1, which plots the evolution of the respective sectoral rates of profit and absolute magnitude of ground-rent appropriated by landowners between 1993 and 2019.

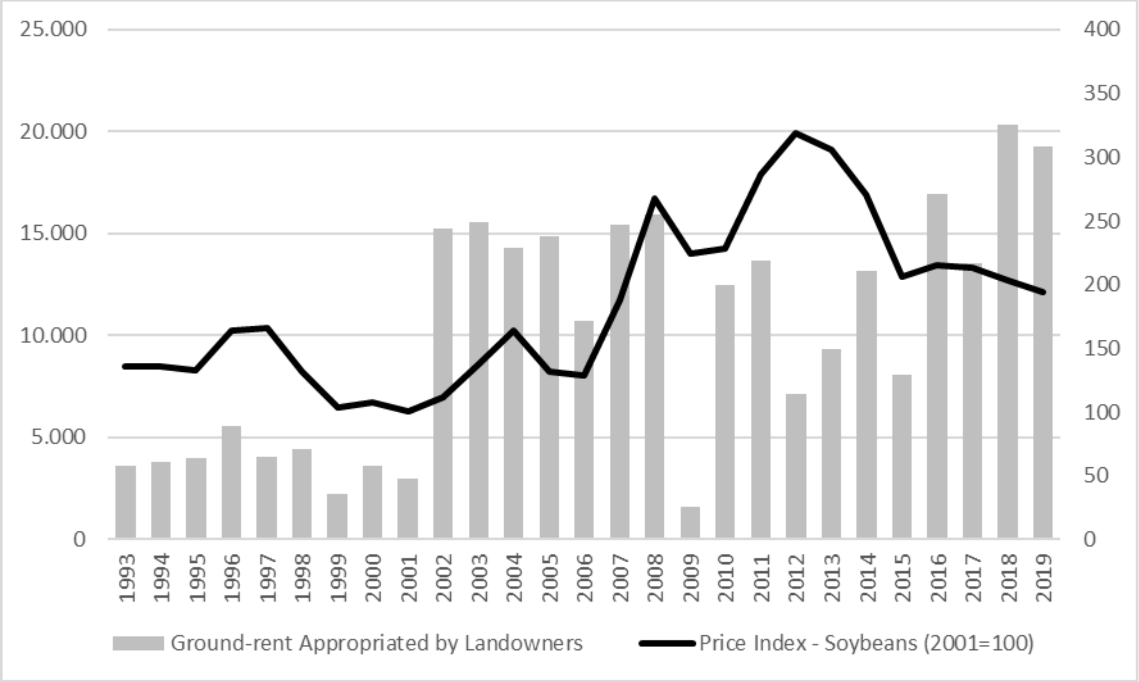
Figure 1: Agrarian vs. Industrial Profitability (Landowner´s Ground-rent). Source: See methodological appendix.



In addition to showing the existence of systematic surplus profits in the agrarian sector (i.e. ground-rent), this figure also evidences the remarkable increase (more than three times) in its absolute magnitude during the 2000s. More specifically, this means that during the period 2002-2019, around a third of the agrarian net product (which amounts to 2% of Argentina´s GDP) was essentially “squandered” in the reproduction of landowners as a parasitic social class. As is well known, this rise relates to the surge in agrarian production during the so-called (primary) “commodities boom”. Thus, except for 2009, which was doubly affected by both a draught and the plummeting of prices of agrarian commodities in the context of the global financial crisis, landowners benefitted from the general prosperity of the agrarian sector in the form of an absolute increase in the mass of social wealth that they appropriated as a class.

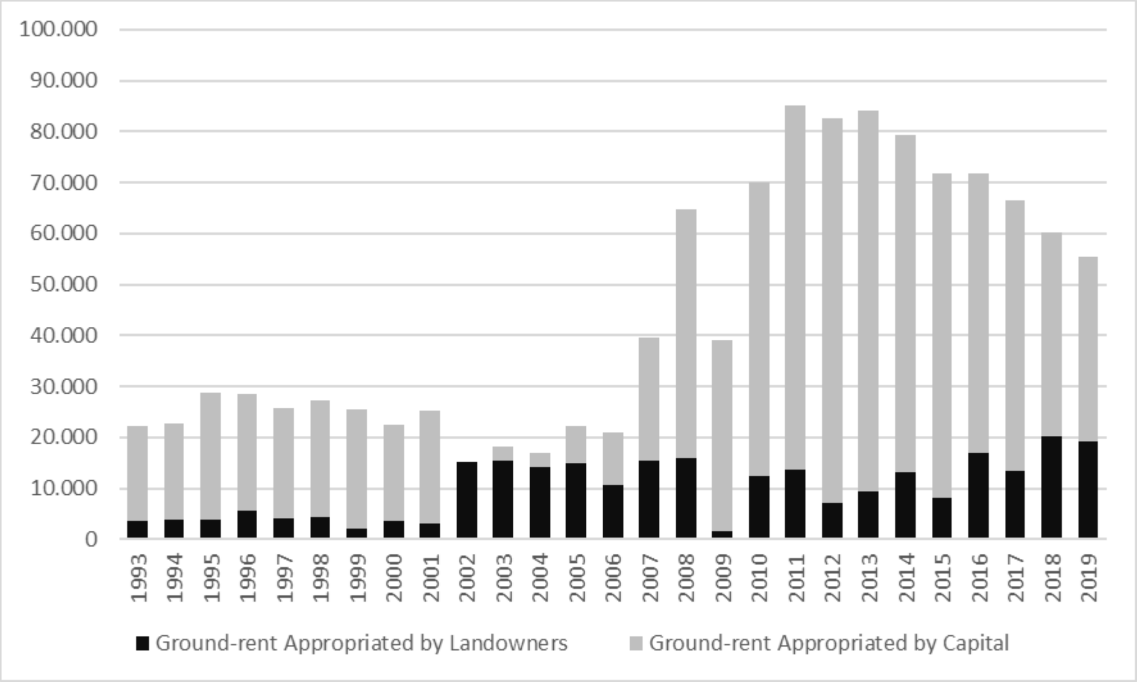
Yet, on closer inspection of shorter-term variation of agrarian prices, it is possible to discern a certain delinking between the movement of international prices, hence the mass of *total ground-rent* flowing into Argentina through the export of agrarian commodities (paid more dearly at the expense of surplus value produced abroad by virtue of the “false social value” contained in them), and the portion of ground-rent *pocketed by landowners*. For instance, between 2010 and 2012 there is a pronounced hike in agrarian prices (of more than 40%), but it did not translate into the growth of ground-rent captured by landed property (which actually contracted during 2012 and 2013). Conversely, when in 2014 agrarian prices reversed their upward trend to henceforth stabilise until 2020 at around 35% below the peak of 2012, the mass of social wealth appropriated by landowners actually grew to unprecedented levels.

Figure 2: Landowner´s Ground-rent and Agrarian Prices. Source: See methodological appendix.



Now, what is the reason for this delinking between the movement of international agrarian prices and the magnitude of ground-rent appropriated by landowners? As argued in the previous section, this is explained by state policies which mediate the diversion of the course of ground-rent flowing into the country towards capital in general; among them, the establishment of taxes on agrarian exports and the regulation of the exchange rate (more concretely, the overvaluation of the national currency, achieved through a rate of devaluation that lags behind inflation), stand out.

Figure 3: Share of Capital and Landed Property in Total Ground-Rent. Source: See methodological appendix.

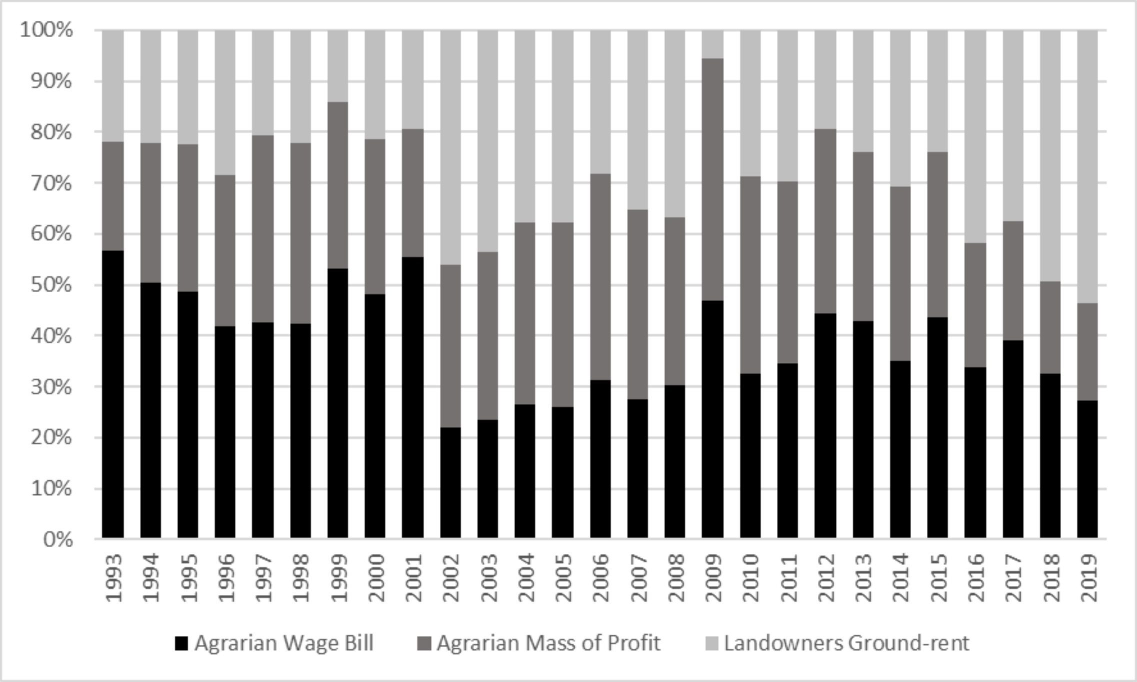


Indeed, as this third figure makes evident, the increase in total ground-rent derived from the hike in international prices since 2007 ended up mostly in the hands of capital in general. Unsurprisingly, this process led to a heightening of the political confrontation between the governing "populist coalition" (the so-called "Kirchnerist" administration) and the landowning class (represented in different "rural" organisations), especially since 2008 (Pérez Trento 2021). The material basis of the growing discontent of the personifications of landed property lied not only in the decrease of their share of total ground-rent but was actually compounded by the actual fall in the absolute magnitude of social wealth appropriated as a class. Between 2010 and 2015, landowners pocketed, on average, 25% less ground-rent than in the period 2002-2008. As a matter of fact, the contrast with the latter period is even starker: from

2002 until 2006, landed property had actually increased its appropriation of ground-rent vis-à-vis the levels reached in the 1990s up to, and including, 2001. Moreover, this took place in the context of a sharp drop in the inflow of total ground-rent into the country, which thereby meant that intersectoral transfers into the rest of the economy concomitantly fell (and virtually faded away between 2002 and 2004). A similar pattern can be discerned during the right-of-centre Macri administration from 2016 until 2019, albeit on a smaller scale. In effect, on the one hand, the pronounced fall in international prices of agrarian commodities since 2014 led to a decrease in the total ground-rent available for appropriation. On other hand, the substantial reduction of export taxes, coupled with the devaluation of the national currency after the sudden lift of all foreign exchange controls, meant that both the absolute level and the share of ground-rent captured by landowners increased.

In sum, these estimates illustrate the connection between the ebbs and flows of the availability of total ground-rent in the national space and its capture by both the different social subjects comprising the agrarian sector and that by the accumulation of capital in general outside agriculture. When climatic conditions (i.e. draughts or floods) or international prices lead to the shrinking of total ground-rent, given its key role in the general reproduction of the national process of accumulation, the need arises to sustain the scale of agrarian production. Consequently, a reduction of export taxes and/or a devaluation of the (usually overvalued) national currency takes place, with a view to increasing the domestic price of agrarian commodities and thereby shielding the sector from the negative effects of the crisis. Thus, the development and resolution of the accumulation crisis is achieved through the growth of the relative share of landed property in the appropriation of total ground-rent. Under particularly dire economic circumstances, it might even lead to the absolute growth in the mass of social wealth captured by landowners, as happened in both 2002 and 2016. In other words, the resolution of the crisis is in all cases achieved at the expense of the share of agrarian capitalists and, fundamentally, that of agricultural workers (as shown in the next figure) and, more generally, by curtailing the transfer of ground-rent to capital in general across society.[8]

Figure 4: Class Distribution of the Agrarian Net Product. Source: See methodological appendix.



---

[8] For a more extended discussion of the changing material conditions of reproduction of agrarian wage-workers during this period, see Villulla (2021).

At this juncture, it is interesting to consider against this backdrop the ideological and political forms of subjectivity and action which have mediated those fluctuations in the magnitude, and the changes in the share, of the inflow of ground-rent into Argentina. Specifically focusing on the personifications of landed property, two kinds of phenomena can be discerned as the underlying determinants of their antagonistic stance towards state policies that channel a portion of ground-rent into the accumulation process of capital in general.[9] In the first place, as Iñigo Carrera (2008) points out, the concrete mechanisms adopted by intersectoral transfers of social wealth are of the essence, particularly as far as it concerns the ideological dimension of the political consciousness of landowners. In this sense, the overvaluation of the national currency stands apart from other, more direct or overt forms of diverting the course of a portion of ground-rent into the pockets of capital (such as special export taxes on agrarian commodities), for its universal scope and relatively opaque or "invisible" nature. To a large extent, this helps explain its predominant and recurrent character over the historical course of capitalist development in Argentina. It also allows to understand the support of landowners to, or even outright participation in, political regimes whose main economic policies included the overvaluation of the national currency.

---

[9] In other words, on the grounds spelled out earlier on (see fn. 2), the following discussion does not apply to the rural surplus population that constitutes the social determination of most "peasants" in the rest of Latin America. As already mentioned, for those social subjects the appropriation of ground-rent is entirely immaterial for their conditions of reproduction and, therefore, for the constitution of their political subjectivity.

Yet, the potentiality of this modality of appropriation of ground-rent by capital to pacify the opposition of landowners and proceed in comparatively “harmonious” ways, largely depends on the existence of a single foreign exchange rate regime. By contrast, when the overvaluation of the national currency operates in a context of foreign exchange controls, with a dual or multiple exchange rates regime (whether formal or informal), “parallel” exchange rates bring to view the “drain” of social wealth entailed by the overvaluation of the “official” exchange rate for exports. Thus, landowners tend to radicalise their political opposition to state policies that mediate the diversion of the course of ground-rent. In this sense, this latter scenario tends to resemble that of direct, and thereby more conflictive, forms of appropriation of ground-rent, such as regulation of domestic prices of staple foods or special export taxes on agrarian commodities. The latter, in particular, carry a quantitative limit in their capacity to act as vehicles for the appropriation of ground-rent. In effect, beyond a certain threshold, they clash with the “non-confiscatory” juridical principles that structure the fiscal powers of the capitalist state.

In the second place, there is the sheer material determination of the political consciousness of landowners, which we can sketch out with a brief look at the “politics of intersectoral transfers” in the last three decades in Argentina. The so-called “convertibility regime” implemented during the 1990s, which pegged by law the Argentine peso to the US dollar, resulted in a very strong overvaluation of the national currency (which was maintained by a mounting foreign debt that would eventually turn impossible to service and led to a declaration of default in 2001). Nevertheless, in the absence of foreign exchange controls, this allowed to hide from view that both the absolute magnitude of social wealth appropriated by landowners and their share in total ground-rent, was in historically very low levels. Despite these comparatively unfavourable circumstances, the personifications of landed property would receive with standing ovation President Menem´s speech at the annual exhibition of the Rural Society of Argentina (the organisation which gathers the larger landowners). Conversely, in the next period (2002-2007), the prosperity enjoyed by landowners by virtue of the sharp increase in their capture of ground-rent, softened the political and ideological impact of the re-introduction of more visible forms of appropriation such as export taxes, which had been eliminated during the 1990s. Relatively moderate taxation rates, coupled with a national currency that remained undervalued until 2007 (upon the heavy devaluation of 2002), also contributed to the momentary pacification of the state-mediated antagonism between capital and landed property (Barlow and Peña 2021).

However, this relatively peaceful scenario would be drastically uprooted in 2008. Faced with the sudden and historically unprecedented hike of agrarian prices in the world market, the left-of-centre Fernández de Kirchner administration unsuccessfully tried to introduce "moving export taxes" which, in that context, would have entailed "confiscatory" levels of taxation and breach the ideological juridical principle of "horizontal fiscal equity". After a long-drawn-out and fierce political conflict with landowners, the Fernández de Kirchner administration was forced to withdraw the said policy proposal. State-mediated recapture of ground-rent by capital thus came increasingly to depend on growing levels of currency overvaluation. However, unlike in the 1990s, and against the backdrop of a default on the public foreign debt that had not been fully resolved, there was no access to global liquidity that could compensate for the drain of US dollar reserves from the central bank in the face of a gradual worsening of the current account of the balance of payments. The state responded by the reintroduction of foreign exchange controls. The ensuing duality in the exchange rate made increasingly visible again the effects of the overvaluation on the appropriation of ground-rent by landowners, who thereby intensified their opposition to the "populist" Fernández de Kirchner administration.

This antagonistic stance of the personifications of landed property dwindled between 2016 and 2019, during the term of office of the "market-friendly" right-of-centre Macri administration, who even appointed a former president of the Rural Society as head of the Ministry of Agribusiness. This renewed "harmony" between landowners and the state had the following basis. As soon as it took office the new administration implemented a drastic reduction of export taxes, lifted all foreign exchange controls, and devalued and unified the exchange rate. Although the overvaluation of the national currency remained in place at least until 2018, the intersectoral transfer of ground-rent tended to become more hidden from the view of landowners. In effect, this was a period in which, due to the substantial drop in international prices of agrarian commodities since 2014-5, total ground-rent available for appropriation in Argentina started to shrink. As happened before in 2002, the continued reproduction of the unity of the accumulation process required that the scale of agrarian production be sustained which, as mentioned earlier on, resulted in the rise of the amount of ground-rent captured by landowners vis-à-vis the average levels registered in the prior "Kirchnerist" administration.

Conclusion

In this article we addressed a series of relatively absent themes in the contemporary literature in Agrarian Marxism and showed their relevance for a regional analysis of contemporary forms of capitalist development in Latin America, which was, in turn, illustrated through a case study of the role of the agrarian sector in capital accumulation in Argentina. The following, we think, are the fundamental points that can be extracted from our discussion.

In the first place, we unfolded the concrete determinations of the general laws of motion of capital that underpin the tendency for the repulsion between normal individual capitals and landed property. Consequently, we argued that the constitution of the peasant as a social subject in the capitalist mode of production expresses their determination as the unity of the personification of a small capital, wage-worker and landowner. On this basis, we explained the "colonisation" of the agrarian sector by small capitals as an expression of the "law of value", which also cast in new light the resilience of peasant production. More generally, this discussion called into question the contemporary consensus over the resolution of the agrarian question.

A corollary of the previous point was the need for a rigorous analysis of modern landed property in the capitalist mode of production and of the determinations of ground-rent as the form of social wealth accruing to landowners as a parasitic social class. More specifically, a case was made for the importance to revisit and clarify the longstanding Marxist debate over the source of surplus-value that constitutes agrarian ground-rent, i.e. whether it originates in the exploitation of workers within or outside agriculture. Our answer to this question paved the way for a discussion of the potentialities of capital in general to recapture a portion of this mass of social wealth to feed its own accumulation.

As a further implication of this, the article made a case for the significance of ground-rent in the unity of its underlying determinations for the comprehension of the specific form in which Latin American national spaces participate in the global process of capital accumulation. In a nutshell, we argued the role of these territories is not simply to act as suppliers of raw materials and staple foods for the capitalist world market but, more importantly, to be constituted as spaces for ground-rent recovery by the global total social capital. It is this qualitative specificity, we further claimed, that explains the limited potentialities of the industrialisation process and the highly contradictory and crisis-ridden character of the economic and political forms of the accumulation process in the region.

Finally, both this general approach and a methodology for the quantitative estimation of ground-rent, were used to shed light on the recent developmental dynamics in Argentina during the so-called “commodities boom” in the 2000s. This allowed us accurately to identify the relationship between the movement of international prices of agrarian commodities and the appropriation of ground-rent by the different social subjects, as mediated by the public policies implemented by the state. Furthermore, this discussion of the quantitative evidence for the fluctuations in the flow of ground-rent laid the ground for a materialist analysis of the political forms taken by the state-mediated antagonistic relationship between the personifications of landed property and capital in general. In other words, the article sketched out the concrete determinations which underlie the political subjectivity and action of landowners as a class.

METHODOLOGICAL APPENDIX

*The respective rate of profit (R) in each sector (agriculture and industry), is obtained as follows:

$R = SV / K$

Where,

SV is total surplus-value appropriated
K is total capital advanced

In turn,

$SV = VA - W - CFK$
$K = CK + FK$ (+ livestock in the agrarian sector)

Where

VA is the value added in each sector
W is the cost of labour-force
CFK is the consumption of fixed capital
CK is the circulating capital advanced
FK is the fixed capital advanced

* Ground-rent appropriated by landowners (LR) is calculated as follows:

$LR = Ka . (Ra - Ri)$

Where,

Ka is the total capital advanced in the agrarian sector

Ra is the rate of profit in the agrarian sector

Ri is the rate of profit in the industrial sector

Dialectics on Its Feet, or the Form of the Consciousness of the Working Class as Historical Subject

Juan Iñigo Carrera

1 Placing Dialectics Right Side Up

In his afterword to *Capital*, Marx defines his method as a dialectical one. In so doing, he explicitly recognises Hegel as 'the first to present its [dialectics'] general form of working in a comprehensive and conscious manner'.[1] However, he also points out:

> My dialectic method is not only different from the Hegelian, but is its direct opposite ... With him it is standing on its head. It must be turned right side up again, if you would discover the rational kernel within the mystical shell.[2]

What does it mean to place dialectics right side up, starting from Hegel's inversion?

The question cannot be avoided, unless someone were to believe that Marx was incoherent and actually based his developments on the logic of Hegel – of which the latter considered his method to be its content[3] – although he stated the necessity of inverting this method.

Could it be about replacing 'idea' where Hegel uses the term with 'matter' in order to reconstruct a dialectical logic?[4] Is it about providing 'materialist content' for Hegel's logic?[5] Is it about placing 'capital' where Hegel places 'idea'?[6] These changes imply changing the content upon which logic operates. But Marx refers to placing the method itself right side up. Therefore, the point is the very form of the process of knowledge.

[5] Levine 2006, p. 49.

[6] Meaney 2002, p. 8; Arthur 1993, pp. 86–7.

Could it be about Marx applying the 'Logic of Essence' where Hegel applies the 'Logic of Being'?[7] In this case, the inversion would only have a partial character, as if it could be said that Hegel's logic uses arms where it should use legs. But the problem pointed out by Marx is that Hegel's method is inverted from head to toe.

Could the change in form mean proceeding from a general logical structure to one particularly appropriate to its object? In an early stage of the development of his thought, Marx asserted:

> However, this comprehension [*Begreifen*] does not, as Hegel thinks, consist in everywhere recognizing the determinations of the logical concept [*des logischen Begriffs*], but rather in grasping the proper logic of the proper object.[8]

Do we thus reach the answer by resorting to a logic that starts from the simplest category which represents the proper object and makes this category develop itself through its own movement, so as to engender a more complex category, and so on, until an integral system of categories which belong to the proper object is completed? For example, is it about the development of the concept of the commodity engendering the concept of money, and the development of the latter engendering the concept of capital, and so on?[9] Marx himself rejects the idealist inversion inherent in such a procedure:

> Apply this method to the categories of political economy and you have the logic and metaphysics of political economy ... which makes them look as if they had newly blossomed forth in an intellect of pure reason; so much do these categories seem to engender one another, to be linked up and intertwined with one another by the very working of the dialectic movement.[10]

Moreover, Marx criticises himself with regard to the risk of letting the form of presentation generate the appearance that his research has fallen into this sort of idealist inversion:

> The product becomes a commodity; the commodity becomes exchange value; the exchange value of the commodity is its immanent

---

[7] Smith 1990, pp. 51–3.

[8] Marx 1970b [1859], p. 92.

[9] Fineschi 2006, pp. 128–9.

[10] Marx 1976b [1847], p. 165.

> money-property; this, its money-property, separates itself from it in the form of money ... It will be necessary later ... to correct the idealist manner of the presentation, which makes it seem as if it were merely a matter of conceptual determinations and of the dialectic of these concepts.[11]

It happens that logic is a constructive necessity produced by thought, whose movement as such is alien to the movement of the necessity that determines the object. Marx develops, apropos of Proudhon, the unavoidable contradiction implied by any attempt to follow in thought, at the same time, the necessity taken from reality and a logical-constructive necessity:

> When M. Proudhon spoke of the *series in the understanding*, of the *logical sequence of categories*, he declared positively that he did not want to give *history according to the order in time* ... Thus for him everything happened in the *pure ether of reason*. Everything was to be derived from this ether by means of dialectics. Now that he has to put this dialectics into practice, his reason is in default ... [N]ow we have M. Proudhon reduced to saying that the order in which he gives the economic categories is no longer the order in which they engender one another. Economic evolutions are no longer the evolutions of reason itself. What then does M. Proudhon give us? Real history ... ? No! History as it takes place in the idea itself? Still less! ... What history does he give us then? The history of his own contradictions.[12]

The problem with logic, whatever its alleged degree of generality or singularity, resides in its exteriority with respect to the real necessity. Every logical representation rules its path based on the substitution of the real necessity by a constructive necessity that appears as bearing the power to put thought into motion:

> Logic – mind's *coin of the realm*, the speculative or *mental value* of man and nature – its essence which has grown totally indifferent to all real determinateness and hence unreal – is *alienated thinking*, and therefore thinking which abstracts from nature and from real man: *abstract* thinking.[13]

---

[11] Marx 1973 [1857–8], pp. 147, 151.

[12] Marx 1976b [1847], p. 169.

[13] Marx 1975e [1844], p. 330.

Once again, what is the point? Let us address the question by reproducing the paths followed by Hegel and Marx as they present the unfolding of their methods.

2 Hegel's Idealistic Construction of 'Pure Knowledge' Which Immediately is 'Fulfilled Being'

Hegel recognises that scientific knowledge, as the 'science of manifested spirit', starts from 'empirical, *sensuous* consciousness', an '*immediate* knowledge', therefore, a knowledge which emerges from practice.[14]

But Hegel idealistically inverts the fact that knowledge is always knowledge of one's subjectivity with respect to the object upon which one is going to act. Instead of facing the question of knowledge as the discovery, by the subject, of the necessity of its action regarding the potentiality of the object, he inverts the question into that of the re-establishment of the identity between the subjective process of knowing and the objective determination of the potentiality, where the former engenders the latter. He thus represents immediate knowledge as pertaining to a subjectivity which confronts itself from its own exteriority, since it is not capable of recognising the object as its own self-realisation. It deals with a subjectivity whose limitation in determining the object resides in that which is not developed even in its self-consciousness as the determinant of the object, in the fact that it does not recognise itself as a determinant.

Consequently, for Hegel, the overcoming of immediate cognition does not consist in the deepening of knowledge of the determinations of the subject and of those of the object, but rather the point is to abstract the movement of knowledge itself, since this movement itself has engendered subjectivity as well as its realisation as objectivity. Therefore, immediate knowledge is not followed by the discovery of the content which determines the necessity of the subject and of the object, by penetrating into this content. For Hegel, the point is simply to penetrate the 'significance ... of immediate knowledge' itself.[15]

Thus, the very forms of the subject's consciousness, already emptied of their historical determinations by having been abstracted from the object of their action,[16] become inverted as if they were the pure object of knowledge which in its movement engenders the consciousness:

---

[14] Hegel 1999 [1812–16], p. 69.

[15] Ibid.

[16] Consequently, free consciousness that bears the alienation in the commodity – this being the historically specific determination of Hegel's own consciousness – is raised to an abstractly free consciousness.

> Spirit ... has shown itself to us to be ... *this movement* of the Self which empties itself of itself and links itself into its substance, and also, as Subject, has gone out of that substance into itself, making the substance into an object and a content at the same time as it cancels this difference between objectivity and content. That first reflection out of immediacy is the Subject's differentiation of itself from its substance, or the Notion's separation of itself from itself, the withdrawal into itself and the becoming the pure 'I'.[17]

The phenomenology of spirit culminates in 'pure knowledge', 'the *Notion* of science', which is the 'absolute truth of *consciousness*'.[18] Upon reaching this point, in which the forms of consciousness have been elevated to the condition of being the pure object of themselves, Hegel considers that 'in absolute knowing ... the separation of the *object* from the *certainty of itself* is completely eliminated; truth is now equated with certainty and this certainty with truth'.[19]

Since for Hegel consciousness has thus overcome 'the difference between knowledge and truth',[20] 'pure science ... contains *thought in so far as this is just as much the object in its own self, or the object in its own self in so far as it is equally pure thought*'.[21] And since 'pure knowing as concentrated into this unity [certainty which has become truth] has sublated all reference to an other and to mediation ... this simple immediacy, therefore, in its true expression is *pure being*'.[22]

Thus Hegel arrives at the point of departure of the *Logic*, which is '*pure science*, that is, pure knowledge in the entire range of its development'.[23] Once this development has been unfolded:

> Thus then logic, too, in the absolute Idea ... is the Idea that has reached ... a likeness corresponding to itself. The method is the pure Notion that relates itself only to itself; it is therefore the *simple self-relation* that is *being*. But now it is also *fulfilled being*, the *Notion that comprehends* itself, being as the *concrete* and also absolutely *intensive* totality.[24]

The relationship that the subject of the action establishes with his/her object by ideally appropriating his/her own potentiality with respect to the object's potentiality in order to transform it, namely, the capacity of the human subject to organise his/her conscious action, appears here completely inverted. Hegel represents it as if it were a particular concrete form of an impersonal rationality, of a self-consciousness, which does not arise from human subjectivity, but, conversely, determines it. Here, freedom is not a historically determined social relation whose development is borne in the development of human subjectivity as it objectively advances in knowing its own transforming powers, and therefore transcending itself. Quite the opposite: Hegel idealistically inverts freedom, creating the appearance that it constitutes the attribute of a self-consciousness that only relates to itself in the complete impossibility of transcending its own identity:

> The Idea, namely, in positing itself as the absolute *unity* of the pure Notion and its reality and thus contracting itself into the immediacy of *being*, is the *totality* in this form – *nature*. But this determination has not *issued from a process of becoming*, nor is it a *transition*, as when above, the subjective Notion in its totality *becomes objectivity*, and the *subjective end becomes life*. On the contrary, the pure Idea in which the determinateness or reality of the Notion is itself raised into Notion, is an absolute *liberation* for which there is no longer any immediate determination that is not equally *posited* and itself Notion; in this freedom, therefore, no transition takes place.[25]

What is the concrete reality of this freedom? It is but each and all of the concrete forms of the social relation in the capitalist mode of production – private property, value, contracts, right, fraud, morality, ethics, family, justice, guilt, police, state, and so on – conceived as forms inherent by nature in human subjectivity by grace of the self-conscious Idea.[26] Thus:

> The state is the actuality of the ethical Idea ... the actuality of concrete freedom ... The principle of modern states has prodigious strength and depth because it allows the principle of subjectivity to progress to its culmination in the extreme of self-subsistent personal particularity, and yet

> at the same time brings it back to the substantive unity and so maintains this unity in the principle of subjectivity itself.[27]

The complete realisation of Hegel's Idea is but the cultivation of the apparently limitless reproduction of the capitalist mode of production with all of its contradictions overcome.

3 Marx's Discovery of Dialectics as the Necessary Form of Revolutionary Consciousness

3.1 *The Analysis*

Marx synthesises his critique of Hegel's method as follows:

> Impersonal reason, having outside itself neither a base on which it can pose itself, nor an object to which it can oppose itself, nor a subject with which it can compose itself, is forced to turn head over heels, in posing itself, opposing itself and composing itself ... If we abstract thus from every subject all the alleged accidents, animate or inanimate, men or things, we are right in saying that in the final abstraction, the only substance left is the logical categories ... [O]ne has only to make an abstraction of every characteristic distinctive of different movements to attain movement in its abstract condition – purely formal movement, the purely logical formula of movement. If one finds in logical categories the substance of all things, one imagines one has found in the logical formula of movement the *absolute method*, which not only explains all things, but also implies the movement of things ... All things being reduced to a logical category, and every movement, every act of production, to method, it follows naturally that every aggregate of products and production, of objects and of movement, can be reduced to a form of applied metaphysics ... So what is this absolute method? ... The purely logical form of movement or the movement of pure reason ... Up to now we have exposed only the dialectics of Hegel.[28]

Next, he observes, 'Hegel has no problems to formulate. He has only dialectics ... [Proudhon] has the advantage over Hegel of setting problems.'[29] By then, Marx had already set his own problem: 'The philosophers have only interpreted the world in various ways; the point is to change it'.[30]

---

[27] Hegel 2008 [1820], pp. 228, 235.

[28] Marx 1976b [1847], pp. 162–5.

[29] Marx 1976b [1847], p. 168.

This problem places us immediately in the field of action. And the first step in the very realisation of action corresponds to its organisation. How could action be organised through a consciousness that goes beyond the interpretation of reality, other than by questioning oneself about the objective potentiality of one's action and, therefore, about this action's necessity? That is, the point is now to answer oneself about the potentiality of one's action *vis-à-vis* the potentiality of its object, namely, about the determination of one's subjectivity as the necessary concrete form of realising the potentiality of the object upon which action is to be taken.

Marx faces for the first time the problem he has posited by reproducing Hegel's course and, consequently, with the perspective that the movement of social life should be explained starting from the movement of the state. Therefore, the overcoming of the barriers to the reproduction of social life should arise from the realisation of the state's ought-to-be. However, just as Marx addresses the practice of such reproduction, he finds that there is a superior social power that imposes upon this assumed ought-to-be, namely, private interest:

> [T]he Assembly degrades the executive power, the administrative authorities, the life of the accused, the idea of the state, crime itself, and punishment as well, to *material means of private interest* . . . [which means to] solve each material problem *in a non-political way*, i.e., without any connection with the whole of the reason and morality of the state.[31]

If the state, and even its idea, are but material means of private interest, is political freedom not then a form of this same private interest? How could the state be the subject which is the bearer of human freedom if the political freedom which constitutes it has private interest as its content? Finally, how is it possible to advance, acting politically in a rational manner, without beginning to respond with regard to the necessity of private interest?

At the point where Hegel's abstraction found an answer by resorting to the state as 'the actuality of the ethical Idea', thus bringing down all antagonism to an insufficient development of that Idea in its historical course, Marx's analysis finds a question, namely, the question about the necessity of the subordination of the state, of politics, to private interest. Therefore, Marx seeks to find the necessity of private interest where it manifests itself in an immediate manner, where the lack of all generic unity represented by the state seems to prevail, that is, in 'civil society', whose quality is that 'the only bond between men is natural necessity'.[32] The question is now about the organisation of the process in which human beings satisfy their natural needs, whose point of departure is the organisation of the process of social production.[33]

---

[30] Marx 1976a [1845], p. 5.

[31] Marx 1975a [1842], pp. 259, 262.

Fifteen years after setting his problem, Marx synthesised the path followed by his analysis:

> My inquiry led me to the conclusion that neither legal relations nor political forms could be comprehended whether by themselves or on the basis of a so-called general development of the human mind, but that on the contrary they originate in the material conditions of life, the totality of which Hegel ... embraces within the term 'civil society'; that the anatomy of this civil society, however, has to be sought in political economy.[34]

Now, the analysis faces the categories of political economy. But as soon as these categories are questioned concerning their necessity, they show that:

> We have proceeded from the premises of political economy ... [I]n its own words, we have shown that the worker sinks to the level of a commodity ... Labour produces not only commodities; it produces itself and the worker as a *commodity* ... This fact expresses merely that the object which labour produces – labour's product – confronts it as *something alien*, as a *power independent* of the producer ... within the *producing activity*, itself.[35]

Since political economy is a system of categories, its critique in search of its necessity as a concrete form of the consciousness that organises this alienated producing activity, therefore, as a form of alienated consciousness itself, points towards its simplest category: 'The first category in which bourgeois wealth presents itself is that of the *commodity*.'[36]

But Marx's analysis could not stop at a category, namely, at a form in which this alienated consciousness conceives, and therefore interprets, its own determinations. His analysis needed to face the commodity itself. He recognises in the commodity the simplest real concrete in which the historically specific character of the alienated organisation of social production is manifested. With this, he recognises the commodity as the concrete from which the reproduction in thought of the determinations of the subjectivity able to supersede the capitalist mode of production must necessarily begin:

[34] Marx 1987b [1859], p. 262.

[35] Marx 1975e [1844], pp. 270–80.

[36] Marx 1973 [1857–8], p. 881.

> In the first place, I do not start out from 'concepts', hence I do not start from the 'concept of value'... What I start out from is the simplest social form in which the labour-product is presented in contemporary society, and this is 'the commodity'.[37]

From the *Grundrisse* to *A Contribution* and *Capital* Marx makes here a definitive step forward in putting dialectics on its feet: in the same way that in biology it is clear that the cell from which one departs is a real concrete and not a concept or a category, the commodity, namely, 'the economic cell-form [in bourgeois society]',[38] is equally so.

3.2 *The Dialectical Reproduction of the Concrete*

Marx presents the point of departure of the dialectical development by stating, 'The wealth of those societies in which the capitalist mode of production prevails, presents itself as "an immense accumulation of commodities", its unit being a single commodity.'[39]

On confronting the commodity as a real concrete and not as a category or a concept, the first knowledge of it could enter an exposition only as a simple immediate knowledge, that is, as the simple observation of a fact for whose necessity the very point of departure cannot account. The supersession of Hegel's inversion is already manifested here in a twofold manner. Against Hegel's abstract 'pure knowledge', we have here the modest determined concrete being of the commodity and the modest immediate knowledge which has not gone beyond the appearance presented by social wealth in capitalist society. Moreover, the same supersession is expressed in the unity itself between knowledge and being: here, the existence of the commodity obliges thought to get into motion from its exterior, far from that 'pure knowledge' from whose immediateness 'pure being' emerged. At the same time, this point of departure is empty of any concept able to be placed in motion, either by imposing upon it a given logical structure, or by expecting that it can get into motion by itself as a consequence of its proper logic.

---

[37] Marx 2002 [1879/1881], p. 241.

[38] Marx 1965 [1867], p. 8.

[39] Marx 1965 [1867], p. 35.

To overcome its immediateness, knowledge needs to confront analytically the commodity in its reality, in search of the necessity that gives it its character as that simplest social form. The point is to confront the commodity in its real existence, in order to analyse it with the purpose of discovering why it presents the peculiar social property of being a use-value that bears the unnatural power of being an exchange-value. Marx performs this analysis, thus discovering that this attribute of the commodity, its value, emerges from its being a materialisation of a labour which appears to lack any specific quality. He raises the question about the necessity of this labour as the determinant of value, a question which can only be answered by analysing this same labour. He thus discovers that the labour represented as the value of commodities embodies a material quality, that of being a productive physiological expenditure of the human body, and a social quality, that of being that physiological expenditure applied to the production of use-values for other individuals, of social use-values, which has been governed in its application by a private consciousness and independently of those individuals.

Thus, the analysis discovers socially necessary abstract labour, performed in a private and independent manner, to be the human activity that provides the commodity with its exchangeability, with its value. Nevertheless, it cannot answer the question of why this materialised labour represents itself in such a way. The only place where thought can objectively examine the manifestation of this necessity is where this necessity realises itself. Therefore, unless one attempts to force a logical movement upon the object, the only path opened to dialectical knowledge is to reproduce by means of thought the movement through which the commodity expresses its value in reality, that is, to follow ideally the commodity in the practical expression of its value in the process of exchange. How is this possible? Firstly, to say that the commodity has an attribute – namely, its capacity to be exchanged – is the same as saying that it has a potentiality to be realised. Therefore, its real determination is its affirmation as this realised potentiality, or in other words, its negation as that same to-be-realised potentiality. Its determination is the affirmation of its attribute through its own negation. Secondly, thought is the subject's capacity virtually to appropriate his/her own potentiality with respect to the potentiality of its object. Thought thus confronts the real commodity and realises its own determination; that is, it affirms itself as a subjectivity that knows, negating itself as a subjectivity that bears knowledge as a potentiality yet to be realised.

Now, it becomes apparent that although the value of a commodity is a quantity of socially necessary abstract labour, it necessarily takes the form of a certain quantity of another privately produced use-value. That is, in the capitalist mode of production, social labour only manifests itself in the form of a thing that relates mutually independent producers with each other. At the moment they act as individual organs of social labour, that is, at the moment they organise their social labour, commodity-producers do not appear to be related between themselves, beyond each of them being the bearer of an individual portion of society's total labour-power. However, they do not bear this portion as the capacity to perform a certain concrete labour already determined by the same organisation of social labour, but in so far as it concerns their capacity to perform labour in general, to expend productively their body in general. Then, each one decides, according to his/her own consciousness and will, namely, in a private and independent manner, in which concrete useful form he/she expends his/her labour-power. Each one thus affirms him/herself as a subject free from all personal dependency with respect to those for whom he/she works.

Nevertheless, the recognition of his/her labour as socially useful is not an attribute that belongs to him/her, but a private attribute of everybody else's will. The capacity to recognise the social character of the labour performed by each one is an attribute inherent to the others, and only once the same labour has been materialised in its product. Therefore, this mutual recognition is established through the equalisation of those products in exchange as materialisations of that sole social relation that existed between their producers at the moment in which each of them had to give, in a private and independent manner, a concrete form to his/her capacity to perform labour in general. Provided this generic labour-power has been appropriately applied, that is to say, provided abstract labour has been materialised in a socially useful concrete form, the materiality of that same labour is represented as the social attribute borne by its product to relate, in exchange, with another which bears the same materialisation. That is, the materiality of socially necessary abstract labour is represented as the value of its product, and this product presents its specific social determination as a commodity. This is the indirect form in which the material unity of social production organised in a private and independent manner imposes itself. The value-form taken by commodities is the general social relation that the private independent producers establish between themselves in an indirect manner.

Given that he/she performs his/her labour in a private and independent manner, the commodity-producer fully controls its individual character, and therefore affirms himself/herself as an individual free from any relationship of personal dependence. However, at the same time, he/she lacks any control over his/her labour's social character. The powers of his/her own individual labour with respect to the unity of the process of social metabolism completely escape his/her control. Consequently, he/she has to submit his/her consciousness and will (which is inherent in a free individual) to the social powers borne by the product of his/her labour. Value, and therefore his/her capacity to take part in the organisation of social labour, and then in social consumption, is not his/her personal attribute. It is an attribute alien to his/her person; it belongs to his/her commodity. The material product of the labour that the consciousness and will of his/hers that is inherent in a free individual have governed confronts him/her as the bearer of a social power that is alien to him/her and to which his/her consciousness and will are submitted. Therefore, the free consciousness and will of commodity-producers are the form in which the alienation of their consciousness and will as attributes of commodities is realised. Their free consciousness is the form taken by their alienated consciousness. Thus, they behave towards the commodity in a fetishistic way.

Starting from the movement of the commodity, we discover alienated consciousness. However, we have not made this discovery by logically developing the category 'commodity', but by reproducing through thought the real movement of commodities. Now, the fact that this alienated consciousness is the one which the commodity-producer employs to govern his/her participation in his/her production confronts us with the following evidence: just as our point of departure was that 'immense accumulation of commodities', alienated consciousness was already present in its realisation at the point of departure itself. Moreover, consciousness is the form in which human subjects bear their capacity to govern their individual labour as organs of social labour. Therefore, regarding commodity-producers, we see that their capacity to govern their individual labour is an attribute that fully concerns their consciousness and will. Nevertheless, at the same time, they lack any control over the social character of their labour. This control is an attribute objectified in the commodity. Therefore, when commodity-producers look at the movement of their own product, what confronts them is the movement of their alienated capacity to govern their social labour. We can then say that, in both *A Contribution* and *Capital*, the point of departure is the specific historical form presented to the subjects of action by their own consciousness in the capitalist mode of production. However, it would have been impossible to begin abstractly from the consciousness itself of commodity-producers, in order to discover free consciousness as the form of alienated consciousness. It is impossible to discover objectively the fetishism of commodities without discovering, first, the specific form in which social labour is organised, which is the production of commodities. Here, the social relation takes form in the consciousness and will of its subjects, and not vice versa.

In addition, let us notice that what confronts us here is not the abstract consciousness of an abstract commodity-producer. Actually, it is the very consciousness which has achieved this discovery, namely, *it is our own consciousness*. Its power to produce the said discovery, and therefore the development of its freedom, is but an expression of the development of its alienation.

Let us continue following the movement of the commodity. The same development of the form of value makes it evident that, even though the general social relation appears to arise *a posteriori* from the material process of production, the organisation of this process requires that one commodity in particular becomes placed apart by the movement of the rest, to act as the socially recognised substantive expression of social labour performed in a private and independent manner. The generalised production of commodities, which makes social wealth appear as an immense accumulation of commodities, implies the developed existence of money. Therefore, the point is not that the commodity has become money, or that the category 'commodity' has engendered the category 'money', by following a logical necessity. The point is that the movement of commodities, namely, the movement of the simplest specific concrete, has placed us in front of the real necessity that determines the existence of money as that objectified expression.

The realisation of commodities as values takes us from production to circulation. When we confronted production, we discovered commodity-producers to be individuals free from any personal dependence who socially relate themselves in an indirect way through commodity-exchange, which operates behind their backs, thus determining their consciousness and will as alienated. Now, in circulation, we see that that indirect relation takes the concrete form of a direct relation, a conscious and voluntary one, as personifications of commodities. Thus we discover that the indirect relation between persons, that is, the economic relation, realises its necessity under the form of a direct relation between personifications, that is, as a juridical relation.

Once again, the accumulation of commodities from which we departed was already mediated in its existence by the juridical relations between commodity-owners, but we were unable to account for these relations at that point. Therefore, those who attempt to start by erasing the specificity of commodities as the social representation of the materiality of socially useful abstract labour performed privately are unable to go beyond the representation of the relationship that exists between economic relations and juridical relations as an external one. Since juridical relations appear to emerge from the will of mutually independent individuals, these conceptions fall victim to the appearance that human beings are abstractly free subjects by nature. From this follows the appearance that alienation is externally imposed upon this nature, thus hindering the recognition of alienation as the content of freedom, and thus the recognition of freedom as a historical social relation.

When we continue by following with our thought the real movement of commodities in circulation, we come to face the concrete form in which the unity between social production and consumption is established. At the stage where we had completed the first development of the form of value, we knew that the only possibility for this unity was the exchange of commodities in the exact proportion in which they were materialisations of the same quantity of socially necessary abstract labour. Now we discover that this determination affirms itself by taking a concrete form that appears as its own negation: those commodities whose production exceeds or falls short, *vis-à-vis* the amount of the solvent social necessity for them at their value, retain their capacity to enter the exchange-relation. But they do so by representing a greater or lesser amount of social labour than the socially necessary one which they actually embody. That is, the realisation of the values of commodities takes concrete shape, in competition, through the selling of commodities above or beneath their values.

Again, the point here is not that the category 'commodity' has logically engendered the category 'competition'. Nor is it the case that we have started by abstracting the commodity from the contingencies of competition, by constructively introducing the simplifying assumption of the immediate realisation of value, and that we are now lifting this assumption. However, the point is also not that the commodity we came to know at first carried in itself, as a latent potentiality, the necessity of engendering the movement of competition. On the contrary, as the elementary form of the initial accumulation of commodities, it was the full expression of the realisation of all the concrete determinations of competition. But it was impossible at that stage for us to apprehend it as such with our thought. Only by beginning with the commodity as the simplest specific concrete could we come completely to appropriate its determination as a full concrete.

As soon as the movement of commodities in circulation demands that we account for its concrete form as competition, we advance another step in recognising the determinations of the consciousness and will of personifications. All the direct relations that they establish in the organisation of social life necessarily have an antagonistic character.

The movement of money as a means of circulation synthesises the determinations of commodities that we have developed thus far. C – M – C: in order to satisfy their human needs by purchasing commodities which bear use-value for them, commodity-producers must have first appropriately acted as alienated personifications in the production and realisation of value. This is a production of use-values whose condition lies in the production of value. Therefore, the objective of the circuit remains beyond it. But when we ideally follow the movement of money, we find out that the very form of this movement confronts us with the functions of money as hoard and as means of payment. Here, commodity-production has as its immediate aim the production of the objectified general social relation: both circuits end in money.

However, the production of the general social relation is, above all, the production of the capacity to open the circuit of the process of social metabolism, that is, the production of the capacity to put into motion individual labours as organs of social labour. Thus, the reproduction by means of thought of the movement of money faces us with the movement of the objectified general social relation, which opens the circuit of production of commodities with the immediate aim of producing more of itself: M – C – M'. Now we recognise the general social relation as capital, that is, as the capacity to put social labour into motion with the immediate aim of producing more of this same capacity. The reason for this circuit resides within the circuit itself. This is a modality of organising the process of social metabolism which has its self-multiplication as its immediate aim. Therefore, this is a social relation that acts as the immediate subject of social production, namely, an automatic organisation of social production. The consciousness and will of the individuals are concrete forms that embody the realisation of this organisation, which as such confronts them as an alien power that dominates them.

We thus discover that commodity-production, from whose simplest concrete expression we departed, is not a production of use-values mediated by the production of value. We recognise this determination now as an appearance. Commodity-production has the valorisation of capital as its immediate aim, and use-values for human life are produced only provided that surplus-value is produced. It is not about the category 'commodity' engendering the category 'capital'. On the contrary, we are now able to recognise that the simplest concrete from which we departed, the commodity, is the product of capital.

At the stage where we recognised the commodity as the simplest concrete presented by the capitalist mode of production, it appeared that no general social relation pre-existed the private decision about the concrete form in which each producer would expend his/her individual portion of society's labour-power. The general social relation only appeared to emerge from private production, ruled by these decisions; so this alienated social relation appeared, then, as the one which determined the consciousness of the commodity-producers, in the form of the necessity to produce value. Now it becomes evident that the objectified social relation pre-existed the putting into action of social labour in a private manner, and that the will of the capitalist, as the personification of capital, is but the concrete form under which this modality of organising social production realises its necessity.

Had we stopped before reaching this point, we would have fallen victim to an appearance which was the inverse of the true content. It would have been impossible for us to discover that the commodity from which we departed is not the simple product of labour, but the product of a labour alienated to capital. Nevertheless, we now recognise the true concrete determination, only because we departed from the commodity as that simplest concrete which confronted us in its immediateness.

As the substantive form of the general social relation, money acting as capital starts by recognising as socially necessary the labour privately materialised in two types of commodities, namely, labour-power and means of production. Then, the labour-power is transformed into living labour, which becomes materialised in a private and independent manner in a new commodity, which in turn is transformed into money, as it is recognised in circulation as a materialisation of socially necessary abstract labour.

When we faced the commodity for the first time, private ownership of one's means of production appeared to be necessary in order to produce it. Now, from a more developed concrete point of view, we see that the content is the opposite one: the worker sells his/her labour-power because, as a free individual, he/she is separated from his/her means of production. Workers are free individuals in a double sense. Freedom, which we knew to be the form of the alienation in commodities, shows through its real movement that, actually, it is the form of the alienation in capital.

It is not about the category 'capital' engendering the category 'commodity labour-power', and even less so about constructing a category 'capital' which satisfies the requirement of treating labour-power as a commodity. What we have done is to reproduce in thought the fact that the general social relation proper to the capitalist mode of production puts itself into motion by determining the worker's capacity to work as its own product.

By thus following the movement of capital, we discover that the true content enclosed by the exchange of commodities as equivalent materialisations of social labour implies that the worker is forced to render more social labour than that materialised in the means of subsistence he/she receives in exchange. That is, the exchange of equivalents is the form taken by the exploitation of the worker by capital.

Initially, when we discovered the commodity as the objectified form of the general social relation in the capitalist mode of production, it appeared that, on the one hand, the direct producer had complete control over his/her individual labour while, on the other hand, no direct control existed over the social character of labour. We can now see that, on the one hand, the direct producer of commodities, the worker, remains a free individual although he/she does not have complete control over his/her individual labour. As this free individual, he/she must obey the authority of the capitalist who has purchased his/her labour-power. On the other hand, the capitalist directly controls the worker's labour, thus controlling a social labour, albeit in a private way. Then, just at this stage of reproducing the movement of the general social relation, we are able to recognise the commodity from which we departed as the product of a certain direct organisation – therefore conscious and voluntary – of social labour. We thus discover that private labour is not merely such, but a contradiction in itself: private labour socially organised within itself.

As an objectified social relation that immediately aims at producing more of itself, capital realises its determination by lengthening the working day. However, this, its very movement, confronts us with the negation of its own reproduction, in so far as the lengthening of the working day undermines the reproduction of labour-power. When we follow the development of this contradiction, we find that its first pole simply reproduces the antagonistic relationship between the workers as sellers of the same commodity, namely, the competition among themselves. On the contrary, the second pole causes this competition to take the concrete shape of its opposite, namely, solidarity as the normal form of selling labour-power at its value.

Thus far, it appeared that the owners of commodities were only able to relate directly with each other as personifications on an individual basis, namely, juridical relations could not go beyond private ones. But after following the movement of capital, we discover that the antagonistic relations between personifications necessarily have a public character, namely, a political character, in so far as the universe of the sellers of labour-power confronts the universe of its purchasers. In this confrontation, the former determine themselves as the working class and the latter as the capitalist class. That is, the indirect organisation of social labour through the valorisation of capital has class-struggle as its necessary concrete form. In other words, in the capitalist mode of production, the political action of social classes is the concrete form taken by capital-valorisation. In turn, the concrete forms of class-struggle confront us with the determination of the state as the political representative of the totality of the individual capitals of society.

Now, this concrete form taken by the buying and selling of labour-power confronts us with the fact that, where the independent action of individual capitals as the subjects of valorisation appeared to be the only possible unity within the process of social metabolism, these are not the actual subjects of the said unity. In a concrete manner, total social capital is the subject of that unity. Therefore, the very alienated subject of this mode of organising the process of social metabolism is the unity of its self-reproduction.

The contradiction between a limited working day and capital's valorisation confronts us with the production of relative surplus-value. In it, the apparently independent movement of each individual capital in pursuit of an extraordinary surplus-value, achieved by developing the productivity of its workers, results in the reduction of the value of the workers' means of subsistence, and therefore the reduction of the value of labour-power and, finally, the increase of the rate of surplus-value.

Let us follow the movement of capital into the production of relative surplus-value and leap forward, for reasons of brevity, to its most powerful form: the system of machinery of large-scale industry. Now, we are able to recognise that the commodity from which we departed was the concrete realised form of very different determinations from those we were able to discover in it as the simplest specific concrete. As that simplest concrete, we knew it as the product of a free individual, who as such exerted complete control over his/her individual labour but lacked any control over its social character, so he/she had to alienate his/her consciousness to the social powers of the product of his/her labour, or, in other words, he/she had to produce value. The development of capital as the subject of the production of relative surplus-value shows us now, firstly, that the commodity from which we departed concretely is the product of the labour of a collective of doubly-free individuals. Secondly, this collective worker consciously governs the labour of its individual organs by means of a production-plan elaborated by an objective, namely scientific, consciousness. Therefore, the collective worker acts with complete control over the unity of its labour as a private organ of social production. However, it lacks any control over the general social character of its labour. Consequently, it has to alienate its consciousness in the service of the social powers of the product of its labour, that is, it has to produce surplus-value.[40]

Thus far, we have followed capital along the complete movement of its circuit of valorisation, that is to say, along the process within which surplus-value emerges from capital. The only movement that capital presents us, beyond this circuit, is the reproduction of this same circuit. As we follow this reproduction, we are confronted by three contents that appeared inverted in the buying and selling of labour-power in circulation, beyond the exchange of equivalents as the necessary form of exploitation. Firstly, under the form of the worker's freedom, he/she is a forced labourer for total social capital. Secondly, under the form of the worker's personal interest in reproducing him/herself, the need of capital to reproduce labour-power is achieved. Thirdly, under the form of private property based on one's own labour, private property based on the gratuitous appropriation of the product of others' labour asserts itself.

---

[40] Iñigo Carrera 2008 [2003], pp. 15–23.

Certainly the latter determination was present in the commodity from which we departed. Why did we not depart directly by making evident this actual content? Because it would have implied we were attempting to discover the necessity borne in the commodity produced by capital by turning the point of departure into an abstraction. Given its own aim, the dialectics that reproduces the concrete in thought can only start from the immediacy with which the unity between the subject and the object (the subject's own alienated social relation) actually confronts the former under its simplest concrete form.[41]

As we follow the reproduction of capital, we find out that the expansion of the private capacity directly to organise social labour develops beyond the concentration of each individual capital, through the centralisation of capitals. And in this double movement, we confront the most developed concrete form of the contradiction that emerges from the fact that the immediate object of social production is the extensive and intensive multiplication of the capacity to put social labour in motion. This attribute determines the capitalist mode of production as a revolutionary one, with respect to the development of the productive forces of social labour. Nevertheless, the same attribute determines it as a barrier to this development. Its extreme expression in this sense is the transformation of an increasing part of the working class into a surplus-population for capital, that is, for its own general social relation.

The reproduction by way of thought of the movement of the materialised social relation brings us now to the specific historical determination of the capitalist mode of production. This is the development of the productive forces of labour by means of the ever increasing socialisation of private labour. The socialisation of labour implies that consciousness is able to govern the organisation of the process of social metabolism by objectively knowing the potentiality of human productive activity with respect to the potentialities presented by its environment. Private labour implies that consciousness is unable to know in an objective manner the same potentialities and their unity, as they confront it as powers materialised in the products of labour to which it is submitted. The capitalist mode of production is itself a contradiction in constant development towards its own supersession through the complete socialisation of labour.

4 Dialectics as Reproduction of the Concrete by Way of Thought and Its Subject

To supersede the constructive necessity that rules the path of thought means to leave thought without any necessity to follow other than that with which the movement of its object faces it. The point is to develop 'a reproduction of the concrete by way of thought'.[42]

Given its very form, this reproduction cannot take an autonomous shape, constructed by the proper movement itself of the categories of thought abstracted from their object. Then, the question here is as follows: upon which concrete could the method of the reproduction of the concrete by way of thought be developed for the first time in history?

Knowledge is the form in which the subject organises its action of actually appropriating its environment, by virtually appropriating the potentiality of its action with respect to the potentialities that its environment offers it. More specifically, consciousness is the form in which the individual human subject rules his/her action as an organ of the process of social metabolism based upon labour. Consciousness is thus the form in which the human subject carries in his/her person his/her social relation.

Therefore, firstly, the object of human knowledge is always the knowledge of one's own subjectivity. Secondly, the form of consciousness, namely, the method by which the human subject produces his/her knowledge, is in itself a form of his/her own social relation. As it is a social relation, far from being a natural form, the method of knowledge is a historically determined form. In this historical determination, Marx opposes his method to Hegel's:

> In its mystified form, dialectic ... seemed to transfigure and to glorify the existing state of things. In its rational form it ... is in its essence critical and revolutionary.[43]

A consciousness whose method divorces the movement of thought from the actual movement is neither an aberration nor an expression of 'inadequacy' or 'immaturity', as Hegel believed concerning formal logical representation.[44] It is a consciousness whose social being inhibits it from fully appropriating its own real powers. Thus, these very powers confront it as powers it is unable to control. It is an alienated consciousness. Instead of being able to advance by reproducing the real necessity embodied in its object, it needs to replace this necessity with an ideal constructive necessity, with a logic that puts into motion a system of categories, in order to appear as the most pure expression of an abstractly free subjectivity.

---

[42] Marx 1973 [1857–8], p. 101.

[43] Marx 1965 [1867], p. 20.

[44] Hegel 1999 [1812–16], pp. 38, 685.

Therefore, the need to develop a dialectic the inverse of Hegel's – a dialectic that replaces constructive necessity with the reproduction of real necessity in thought – finds its basis in a form of a specific historical development of the productive forces of social labour. It arises from the need of the process of social metabolism to invert the mode by which it rules itself. That is, this dialectic has its point of departure within a mode of production in which the subject lacks complete control over the social powers of his/her own labour. Thus, these powers confront him/her as an objectified attribute of the material product of that labour and, therefore, as alien to his/her own subjectivity. Therefore, even the objective consciousness (namely, scientific consciousness) of the said subject needs to stop at that appearance. And this need takes concrete shape in a method of cognition that substitutes the necessity inherent in its object with an ideal constructive necessity alien to that objectivity. The radical inversion of this mode of regulating the process of social metabolism implies that the subject's consciousness reaches the complete domination of his/her condition as an individual organ of social labour and, therefore, that the subject's consciousness recognises the power of social labour as his/her own power. However, this new form of consciousness can only be engendered by the development of the pre-existent one. Therefore, its birth appears as the inversion of the most powerful form of the pre-existent method. Thus, the production of the new consciousness takes concrete shape in the method of cognition that, given that it has the necessity itself of its object as the only necessity to follow, forces its subject to face his/her own alienation. And this is the first step given by that subject in the historically specific development of his/her freedom.

The production of this consciousness is, therefore, the concrete through which the method of the 'reproduction of the concrete by way of thought' necessarily could be developed for the first time in history.

Hegel's *Science of Logic* is the social objectification (a text) of the process in which a consciousness, historically determined by its social being, produces itself on the basis of stopping at the appearance of being an abstract self-consciousness, which in its own movement engenders the real. It is the most developed expression of an alienated consciousness which, in order to reproduce itself in its alienation, needs to take the inversion inherent in any logical representation to its final consequences.

To presuppose the requirement of a logical necessity to apprehend any real concrete in thought is, by itself, to presuppose that the real concrete lacks all proper necessity to be mentally followed. If real necessity existed, what sense would there be to resort to a mental constructive necessity instead of simply following the development of the real one with our thought? Therefore, the real forms must appear as being unable to relate, to move by themselves, at the beginning of the process of representation. Nevertheless, when they emerge from this process, they do so full of the relations that logic has established between them.

However, Hegel does not consider concrete forms to be unable to move by themselves. Instead, he discovers the form of the real movement, namely, self-affirmation through self-negation.[45] Nevertheless, at the same time, he reproduces the appearance proper of the representation by inverting the said movement, as if it emerged from the movement of a consciousness that has itself as its sole determination, of a self-consciousness:

> Accordingly, what is to be considered here as method is only the movement of the *Notion* itself, the nature of which movement has already been cognized; but *first*, there is now the added *significance* that the *Notion is everything*, and its movement is the *universal absolute activity*, the self-determining and self-realizing movement . . . The method . . . is therefore not only the highest *force*, or rather the *sole* and absolute *force* of reason, but also its supreme and sole *urge* to find and cognize *itself by means of itself in everything*.[46]

However, by discovering that self-affirmation through self-negation is the simplest and more general form of determination, Hegel takes philosophy to the end of its historical possibility to bear the advance of the objective consciousness in the organisation of social metabolism. He does so, as the very form of his method makes evident the need for the missing final step, in which real necessity is put in the place thus far occupied by ideal necessity. After Hegel, philosophy can only withdraw towards the rational cultivation of the purest formal exteriority (logical positivism) or towards the cultivation of the crudest irrationality (Nietzsche, postmodernism).

Capital is not a concept whose movement obeys the necessity imposed upon it by thought. The relation is completely the opposite. Capital is a general social relation, that is, a mode of organising social labour and, therefore, social consumption. In this mode of production, the organisation of social labour within each unit of production is an attribute that privately pertains to it. Conversely, each productive unit lacks control over the general social character of the labour it performs. Social labour is organised in a private and independent way. The unity between social production and consumption is thus established in an indirect manner. The capacity to privately organise social labour operates as an attribute materialised in the product of the same labour. At the same time, the immediate aim that rules the putting into action of social labour is not the production of social use-values, but the expanded reproduction of the same objectified capacity to put into action social labour in a private manner. The objectified social relation is the one that puts into action social labour in order to produce more of itself. Such is capital's essential determination.

---

[45] Marx 1975e [1844], p. 332.

[46] Hegel 1999 [1812–16], p. 826.

Again, consciousness is, above all, the capacity of human subjects to rule their own individual labour as organs of social labour. However, in the capitalist mode of production, this power confronts its subjects as a power that belongs to the material product of their social labour. That is, the determination proper of the subjects' consciousness confronts their consciousness itself as a power located beyond it, as an autonomised capacity to put into action social labour which their consciousness itself must obey, that is, of which consciousness must act as a concrete form of realisation. As such, the said autonomised capacity puts consciousness into movement. In reality, the movement of capital puts thought into movement, determining it as an alienated thought.

As a historical form of the development of the productive forces of social labour, capital determines a specific movement of consciousness. The specifically capitalist form of developing the productive forces of social labour consists in the progressive socialisation of private labour. That is, it consists in the development of the capacity to organise social labour through the objective knowledge of one's own determinations, as a concrete form of the realisation of the development of the organisation of social labour as the negation of such objective knowledge. The development of the productive forces of immediately social free labour as an attribute of its very negation, namely, of private labour, is the contradiction that synthesises the historical potentialities and the absolute limit of the capitalist mode of production. And the transformation of the materiality of the labour in which the development of the said contradiction takes concrete form (the production of relative surplus-value) determines the working class to be the subject whose action realises such development.

The capitalist social relation itself needs to engender this social subject, which produces its consciousness under the form in which every constructive necessity – that as such seems to make thought move by itself independently of the actual movement of its object – must disappear. At the same time, the place of this constructive necessity can only be taken by the reproduction in thought of the movement of the very necessity of the real concrete. Therefore, it is about a subject whose general social relation provides it with no starting point other than being in possession of an alienated consciousness and, consequently, a consciousness which is a prisoner of the idealistic inversions of logical representation. But it is about a subject determined by its general social relation as the bearer of the necessity to develop its consciousness up to the point of freeing it from any inverted construction. It is, therefore, about an alienated subject whose social being makes it the active subject of the revolutionary transformation of the mode of organising the process of social production, which it accomplishes by abolishing all alienation. The reproduction of the concrete by means of thought, through which every subject rules his/her individual labour as he/she completely knows him/herself as an organ of social labour, thus asserts itself as the concrete form of the general social relation.

Marx's *Capital* is the social objectification (a text) of the process in which, for the first time in history, the movement of the general social relation of the working class as an alienated subject confronts this subject with the necessity to rule its conscious action by giving an account of its own alienation, which it can do because it has the real development of the latter as the only source of its own flow. This alienated subject, which advances in its freedom by becoming aware of its alienation, thus becomes aware of the historical power that this same alienated social relation provides it as the necessary subject of its supersession. And knowing such powers means nothing other than organising such radical superseding action. In other words, *Capital* is in itself the development, performed for the first time and in a form that allows its social reproduction, of the alienated consciousness of the working class that produces itself as an alienated consciousness that is aware of its own alienation and of the historical powers it derives therefrom.

Method: From the *Grundrisse* to *Capital*

Juan Iñigo Carrera

Questions of method: concerning the point of departure

In August 1857, Marx began writing the drafts of what was eventually to become *Capital*, now published as the *Grundrisse*. In the opening lines of the manuscript, he states: 'Individuals producing in society – hence socially determined individual production – is, of course, the point of departure'.[1]

In the same notebooks, he laid out the sequence that the development of his ideas was to take: '(1) the general, abstract determinants which obtain in more or less all forms of society, but in the above-explained sense. (2) The categories which make up the inner structure of bourgeois society . . .'.[2]

Marx had earlier established the need for the same point of departure together with Engels.[3] However, barely a year after penning that first draft, and as a direct consequence of it, he started working on the *Contribution to the Critique of Political Economy*, making the commodity his new starting point.[4] From then onwards, Marx not only re-vindicated this latter beginning of the critique of political economy but, when presenting it in the opening paragraph of *Capital*, also stated its necessity: 'The wealth of those societies in which the capitalist mode of production prevails, presents itself as "an immense accumulation of commodities", its unit being a single commodity. Our investigation must, therefore, begin with the analysis of a commodity'.[5]

[2] Marx 1993, p. 108.
[3] Marx and Engels 2004, p. 42.
[4] Marx 1911, p. 19.

Towards the end of his life, Marx once again emphasised the necessity of this starting point: 'In the first place, I do not start out from "concepts", hence I do not start from the "concept of value", and do not have "to divide" these in any way. What I start out from is the simplest social form in which the labour-product is presented in contemporary society, and this is "the commodity" '.[6]

Only the actual argument unfolded in the text of the *Grundrisse* mediates in the shift from the starting point laid out in its first paragraph cited above to the one in the *Contribution*. The text of the *Grundrisse* itself must, therefore, be the place in which to seek the traces left by that transition.

Several Marxist theorists have considered that the change in the point of departure reflects the passage from the process of inquiry to that of presentation, whose different modalities Marx alluded to in *Capital*.[7] Thus, some scholars have asserted that the development leading from the *Grundrisse* to *Capital* essentially pertains to the presentation.[8] Furthermore, others have claimed that the dialectical development only belongs to the method of presentation.[9] Finally, some authors have argued that Marx deliberately tried to conceal the method of inquiry in the published versions of his critique of political economy.[10] The implication of this line of argument is that any attempt to find the key to the method of inquiry would have to focus on the *Grundrisse*, rather than on *Capital*. However, one cannot but wonder whether the change in the point of departure is not, rather, a development of the method of inquiry itself, which only reaches its plenitude in *Capital*. In this case, the key to the question lies in recognising the actual concrete content of that development.

This question of the redefinition of the point of departure places us squarely before another problem. In the *Grundrisse*, Marx begins his study of capitalist economic forms by firstly taking as his object the categories established by political economy. He thus faces the determinations of value by engaging in a critique of the theory of the 'time-chit': 'The point to be examined here is the convertibility of the time-chit. . . . [A] few observations can be made about the delusions on which the time-chit rests, which allow us an insight into the depths of the secret which links Proudhon's theory of circulation with his general theory – his theory of the determination of value'.[11]

[10] Nicolaus 1993, p. 60; Reichelt 1995, p. 41.

One can recognise a similar approach to the real subject matter in his 1844 Paris manuscripts:

> We have started out from the premises of political economy. We have accepted its language and its laws. . . . It is true that we took the concept of *alienated labour* (*alienated life*) from political economy as a result of the movement of *private property*.[12]

In contrast, Marx opens the *Contribution* with his own positive unfolding of the determinations of the commodity. It is precisely this latter development that culminates with the *raison d'être* of the categories of political economy, including the theory of the time-chit. In other words, the critique of political economy no longer proceeds by accompanying the development of the theories of political economy up to the point in which the critical discussion puts it before the need to address the real determination. On the contrary, the critique starts by confronting the real determination itself and follows it in its development to the point where the categories of political economy are revealed as necessary ideological forms of existence of that real determination. This new course of the argument only reaches maturity in *Capital*, especially in the definitive version of the first chapter in the second edition. Marx begins there by unfolding the determinations of the commodity, and concludes the dialectical development contained in that chapter by showing how both classical and vulgar political economy are two necessary forms taken by consciousness held captive by commodity-fetishism.[13] Once again, we face the question of the nature of the methodological change entailed by the modification in the form of Marx's argument. Just as the result of this change materialises for the first time in the *Contribution*, we are only able to track down the path of its development in the text of the *Grundrisse*.

Representation or reproduction of the concrete

The second way in which the point of departure is transformed puts us before a third methodological issue that is far more intriguing and complex. No reader, much less one well versed in current scientific research-methods, could have failed to notice a peculiar aspect of the aforementioned quotation from the *Notes on Adolph Wagner*: 'In the first place, I do not start out from "concepts". . .'

---

[11] Marx 1993, p. 136.
[12] Marx 1992a, p. 322, 332.
[13] Marx 1965, pp. 80–3.

How so? Is not the representation of reality that arises of necessity from the definition of concepts or theoretical categories the only method of developing scientific knowledge? Nowadays, two main forms of human knowledge can be distinguished: intuition, namely immediate non-rational knowledge, and rational conception, namely the representation that starts from concepts and establishes relations among them according to a constructive necessity, that is, a *logic* (more on this below). However, in the *Grundrisse*, Marx opposes a third form of knowledge to those two, which he defines not only as having a rational character, but also as a way of overcoming representation as such: 'The concrete is concrete because it is the concentration of many determinations, hence unity of the diverse. It appears in the process of thinking, therefore, as a process of concentration, as a result, not as a point of departure, even though it is the point of departure in reality and hence also the point of departure for observation [*Anschauung*] and conception [*Vorstellung*].[14] Along the first path the full conception was evaporated to yield an abstract determination; along the second, the abstract determinations lead towards a reproduction of the concrete by way of thought'.[15]

The name of each method itself indicates the specific differences between them. To *represent* the concrete means taking its manifestations as they are presented to us at face-value, in order to present them once again as if they were subject to relationships of necessity dictated by the constructive logic of representation itself. Those manifestations can be either those that appear immediately to our eyes, or those that can only be apprehended through the mediation of an analytic process that has managed to abstract the manifestations themselves based on the (more or less) universal features of the concrete in question. However, regardless of the degree of detail achieved by the analysis, the necessity represented always corresponds to the externality of the manifestations that it has put in relation to each other. Penetrating this externality to extract the true necessity at stake is, by definition, alien to its aim.

By contrast, *reproducing* the concrete by means of thought implies that the course taken by the progression of ideas must be the same as that followed by the development of the necessity of the concrete, namely by its determination, in its real actuality. The movement of thought cannot introduce any necessity not found in its real object. Thus, it cannot resort to any constructive necessity that establishes a certain point of departure. Consequently, this form of knowledge cannot start out from concepts, but only from the actual concrete.

---

[14] Nicolaus translates *Vorstellung* as 'conception'. Hegel uses the term *Vorstellung* to refer to thought that stops at the apparent exteriority of its object, precisely in opposition to conceptual thought, which, always via an idealist inversion, engenders the object as a concrete form of realising its concept (see Inwood 1992, pp. 257–9). Putting the question of the forms of knowledge back on its feet, although a conception is the result of the process of representing something, the actual term *representation* expresses directly the very form of the method utilised.

[15] Marx 1993, p. 101.

The existence of two methods of rational thought that are essentially at odds may appear strange. However, this could not have been the case for Marx, who was very familiar with Hegel's work and who had 'skimmed' once more through *The Science of Logic* while writing the *Grundrisse*.[16] In his texts, Hegel persistently contrasts dialectics – which he terms 'speculative thought' in his idealistic inversion – and the method of representation that bases its constructions on formal foundations, that is, on the formal externality of its object.[17] However, his idealistic inversion made him stop at the appearance that the unfolding of logical necessity itself engenders the real. His own theory was thus condemned to being a representation of reality.

Now, beyond principally formal references, the contrast between *representation* and *reproduction* has received scant attention from Marxist theorists working on the issue of method in the *Grundrisse* and its relationship with Hegel's method. In general terms, the specificity of the method developed by Marx is presented as if this were an issue bearing on the form of the constructive necessity, hence of the logic used, and thus as if it were about the difference between two kinds of representation. In some cases, *representation* and *reproduction* are employed as interchangeable terms.[18] On the other hand, even those who recognise that Marx opposes his method to representation tend to replace the term *reproduction* [*Reproduktion*] with that of *reconstruction*.[19] The etymology of this word refers to the joining of elements that are mutually external to each other. In that condition of mutual exteriority, they therefore lack any immanent necessity to establish a relation. The latter can only be established through a necessity stemming from the constructive process itself rather than from its object. As Hegel pointed out – precisely in order to show the limits of representation – maybe this is a case in which 'that which is known in general terms, precisely for being *known*, is not acknowledged'.[20]

Now, it is clear that since its foundation political economy has known no other method than that of logical representation. Yet, the paragraph quoted above where Marx presents the method of the *reproduction* of the concrete flows directly from this one:

---

[20] Hegel 1977, p. 18; translation modified.

> The economists of the seventeenth century, e.g., always begin with the living whole, with population, nation, state, several states, etc.; but they always conclude by discovering through analysis a small number of determinant, abstract, general relations such as division of labour, money, value, etc. As soon as these individual moments had been more or less firmly established and abstracted, there began the economic systems, which ascended from the simple relations, such as labour, division of labour, need, exchange value, to the level of the state, exchange between nations and the world market. The latter is obviously the scientifically correct method.[21]

How is it possible for Marx to say that the method used by political economy is the right one, while at the same time defining the outcome of its deployment as *reproduction*, in opposition even to political economy's own self-understanding of the nature of its theories as *representations* of reality?

Furthermore, in the afterword to the second edition of *Capital*, as in the *Theories of Surplus Value*, Marx indicates how the method used by classical political economy leaves room for the element of vulgar political economy to emerge. He also highlights how, on the basis of such a methodological approach, the historical development of political economy reveals it as a form of consciousness doomed to lose all scientific content in order to become the pure apology for the capitalist mode of production as the latter progresses towards its own supersession:

> For the development of political economy and of the opposition to which it gives rise keeps pace with the *real* development of the social contradictions and class conflicts inherent in capitalist production. Only when political economy has reached a certain stage of development and has assumed well-established forms . . . does the separation of the element whose notion of the phenomena consists of a mere reflection of them take place, i.e., its vulgar element becomes a special aspect of political economy. . . . Since such works only appear when political economy has reached the end of its scope as a science, they are at the same time the *graveyard* of this science.[22]

In utter contrast to this destiny of political economy inherent in its method, Marx defines the historical role of the method of the critique of political economy, 'my dialectical method', by stating: 'In its rational form it is a scandal and abomination to bourgeoisdom and its doctrinaire professors, because it includes in its comprehension and affirmative recognition of the existing state of things, at the same time also, the recognition of the negation of that state, of its inevitable breaking up; because it regards every historically developed social form as in fluid movement, and therefore takes into account its transient nature not less than its momentary existence; because it lets nothing impose upon it, and is in its essence critical and revolutionary'.[23]

---

[21] Marx 1993, pp. 100–1.
[22] Marx 1971, pp. 921–2.

On the other hand, the same point made by Marx about the two historical stages followed by classical political economy – from its seventeenth-century beginnings to its maturity with the works of Smith and Ricardo – makes it clear that its naturalisation of capitalist relations does not derive, *pace* Rosdolsky,[24] from the fact that it confines its procedure to the analytical stage without subsequently returning to the more concrete forms.

Once we disregard any possibility of incoherence on Marx's part, the only possible answer is that, while both methods (logical representation and the ideal reproduction of the concrete) go through the two-fold path of analysis and synthesis, each form of scientific knowledge undertakes each of these two steps in different concrete forms. These concrete forms need to be so different from each other that their respective outcomes are, in one case, the *representation* of the concrete in thought and, in the other, the *reproduction* of the concrete in thought. What is more, their difference must be so profound that while the historical development of the former turns it into 'the graveyard of science' and the apologetic for capitalist social relations, the other becomes the scientific form of consciousness which buries those social relations. The divergence in historical trajectories does not arise from taking a different real content as an object of inquiry, but from the very form in which the same content is appropriated in thought.

It is thus clear that Marx's methodological remarks at the start of the *Grundrisse* do not constitute an unproblematic synthesis that could straightforwardly resolve the issue of the specificity of the method of the critique of political economy. On the contrary, they raise more questions than answers. The 1857 introduction provides no more than a concise rendition of certain aspects of the dialectical method whose content must be further developed in a critical fashion. In this chapter, we shall therefore firstly elaborate on the question of the difference in form between the representation and the reproduction of the concrete in thought. On this basis, we shall subsequently discuss the other two methodological evolutions on which we commented above that lead from the *Grundrisse* to the *Contribution* and *Capital*.

---

[23] Marx 1973, p. 20.

[24] Rosdolsky 1977, p. 567.

The methods of scientific knowledge[25]

Both the representation and the reproduction of the concrete are constructions of an ideal nature, in other words, constructions of thought. As Marx points out, both start by facing a real concrete. Moreover, both aim to appropriate in thought the determinations of the concrete in question with a view to intervene in its development, that is, to act upon it. Both intend to give such an action the character of an action that is objectively aware of its own cause. In this sense, they depart from the premise of not accepting any necessary content other than that found in its object, nor forcing on its object any necessity springing from the subjectivity of the researcher. In turn, this means that they begin by facing the real concrete in order to go beyond the appearance that it presents to immediate cognition in search of its true determination. In other words, both methodological approaches begin with the *analysis* of the real concrete. In the following sections, we explore in more detail each form of the process of cognition in order to bring out the fundamental differences that set the two scientific methods apart.

Logical representation

Let us start by examining the way in which the analysis characteristic of logical representation conceives the foundations of its own objectivity. The latter is seen as ruling out all possibility that an existing concrete may carry within itself a causal necessity other than the immediate manifestation of its very form. On this basis, there is no other possible expression of the general nature of causality other than the greater or lesser regularity of its manifestations. It follows that the analysis that leads from the immediate concrete to the discovery of the most simple and general determination must consist in the identification of recurring attributes.[26] Therefore, the necessity of its simplest concepts and categories is founded on the repeated presence of an attribute in the original concrete. The qualitative development that determines the general, specific and singular is represented indistinctly from, if not confused with, the merely quantitative development of the universal, particular and individual. This also implies that those simpler concepts are obtained by assuming a *purely ideal* concrete bereft of non-recurring real attributes. They therefore cannot correspond to any *actually existing* concrete simpler than that with which the analysis began.

---

[25] I have originally presented the fundamental aspects of the following discussion on method in Iñigo Carrera 1992 and Iñigo Carrera 2008, pp. 235–368.

[26] Hempel 1965, pp. 231, pp. 253–4.

Once the degree of repetition considered sufficient for the abstraction of those general concepts from the original concrete has been achieved, the process must reverse its direction. In this second phase, the representation of the concrete arises as a unity in which the more and less general concepts obtained in the analytical phase are placed in a necessary relation to each other. Thus, on the basis of the simplest necessary element identified in the first phase, progress is subsequently made by re-incorporating the attributes formerly excluded as accidental, or, in other words, by removing 'simplifying assumptions'. However, given that the analysis began by conceiving each concrete as devoid of any causal necessity that transcends the objectivity of its immediate affirmation, the concepts arising from it cannot but preserve this condition. As a result, they must be placed in relation to each other by recourse to a *constructive necessity* that is inevitably external to them and that simultaneously preserves the mutual externality of those concepts in the represented unity. *Logic* is thus this constructive necessity which represents all objective connection as if it were an external relationship between concepts. It gives coherence to the reciprocal externality of all concepts and relationships involved in representation based on its own necessarily tautological nature. Hence the tautological nature of the synthesis itself.[27]

True, most Marxist authors referred to earlier do not necessarily subscribe to this manner of proceeding.[28] They oppose to it what they define as a dialectical approach. However, they rarely explicitly state the specific form that the analysis should take within the dialectical investigation. Thus, it is stated that the key resides in distinguishing between necessary and contingent moments,[29] between empirical and substantive abstractions,[30] or between general and determinate abstractions.[31] These contributions recognise that abstract forms must be sought within more concrete ones. However, they usually do not explain either the way in which this search should be made, or the basis on which those differences could be established. In the cases in which the form of analysis is made explicit, this is sometimes seen as entailing the repetition of common attributes (thus not differing from representational analysis).[32] Alternatively, other scholars have characterised the analytical process in a Cartesian fashion, namely, as the decomposition of the complex totality into mutually external simple elements.[33] Finally, some authors have argued that elemental concepts should be defined in terms of the aim or finality of the theoretical construction, in other words, that they should be posited by the criterion of the researcher *prior to* the scientific development itself.[34]

---

[27] Carnap 1959, p. 143, p. 145.

[28] An obvious exception is that of analytical Marxists. See Burns 2000, pp. 86–98.

[29] Reuten 1988, p. 143.

[30] Bonefeld 1992, pp. 104–5.

[31] Fraser 1997, p. 93.

[32] Dussel 1985, p. 33.

[33] Murray 1988, pp. 121–9; Dussel 1985, p. 51.

Given that the concepts arising from these modes of analysis are bereft of a necessity which would drive them to self-transcendence, the relationship between them is represented by a constructive necessity defined as a *dialectical logic*. In some cases, it is stated that a concept should be logically derived from another until a system is structured, although the concrete form in which this process is to take place is not actually explained.[35] In other cases, the derivation is founded in a parallel with the development of Hegel's *Logic*,[36] or in the doubling of abstract notions,[37] or in the unfolding of determined categories as the condition of existence of determinant ones.[38] Other approaches see dialectical logic as involving the attempt to place the parts in a relationship to the whole, which implies relapsing into a process of synthesis in which the general and specific are reduced to the mutually external nature of the universal and particular.[39] In all cases, the inevitable result is a concrete in thought whose nature as the outcome of a purely ideal intertwining of concepts is beyond question, hence its condition as a systematic conceptual representation in opposition to a reproduction.[40]

Other Marxist conceptions posit that the dialectical-logical development should be driven forward by the tendencies for determinate actions of social agents that are intrinsic to the social form referred to by each theoretical category,[41] or by the practical insufficiency of each form achieved.[42] However, these approaches do not explain how to solve the rift that these procedures generate in the actual consistency of the conceptual development. On the one hand, this implies following a sequence that responds to a constructive necessity, and on the other, a sequence that follows the movement of the real concrete itself.[43]

These ideas have provided the grounds for the claim that developments based on dialectical logic are not tautological in nature.[44] However, the very same developments undertaken with the purpose of structuring a dialectical logic capable of bringing coherence to the representation of the concrete as a unity of opposites have concluded that such logic necessarily requires each of them to be defined as simple immediate affirmations.[45] This is not a circumstantial fact. If each pole were accorded the capacity to affirm through self-negation, it would then have to be recognised as the bearer of a necessity whose realisation would set it into *self*-movement independently of its opposite. In this case, one would have to accept that the introduction of a constructive necessity representing all movement as a relationship between opposites would be redundant. What is more, inasmuch as this logical movement would collide with the real one of affirmation through self-negation, it would lead the process of cognition towards incoherence. Hence the external and tautological nature underlying, in the last instance, all conceptual relationships representing the real movement by means of a dialectical logic.[46]

[44] Arthur 1993, p. 67.

Let us now see how the application of this method appears in the very point of departure of political economy. For example, Adam Smith uses it to ground the simplest determination on which to develop his theory of the organisation of social life. 'The principle which gives occasion to the division of labour', he argues, stems from 'a certain propensity in human nature . . . to truck, barter, and exchange one thing for another' whose discovery lies in observing that 'it is common to all men, and to be found in no other race of animals'.[47]

This same form of analysis appears when Smith has to ground the general determination which dictates that the labour-content of exchange-value is not directly expressed as such, but rather as quantities of another commodity, and, more concretely, as price. The entire foundation is reduced to the assertion that the first expression is 'more frequently' observed and 'is more natural, therefore' than the comparison 'with labour', while at the same time, 'every particular commodity is more frequently exchanged for money than for any other commodity'.[48]

Let us note, in passing, how the recurrence of the most immediate appearance allows this mode of analysis to present it in an inverted form as the true general determination. This is what Hegel had in mind when he said that:

> [S]ince in this procedure the ground is derived from the phenomenon and its determinations are based on it, the phenomenon certainly flows quite

---

[45] Joja 1969, pp. 111–13, 157; Lefebvre 1984, p. 154.

[46] In his defence of dialectical logic, Ilyenkov (1982) falls into circular reasoning by arguing that the identification of the relevant aspect to be abstracted by analysis 'presupposes the comprehension' of its specific role and place in the whole (Ilyenkov 1982, p. 103). In turn, he conceives the process of synthesis as the 'combination' (p. 37) of a pair of the abstracted concepts, which are complementary as each of them presents an aspect lacking in the other (pp. 88–92). Consequently, he can only ground the capacity to identify which pair of opposed aspects is determining in each case by asserting that it 'is an axiom of dialectics' (p. 138).

[47] Smith 1852, p. 6.

[48] Smith 1852, p. 13.

> smoothly and with a favourable wind from its ground. . . . The exposition begins with grounds which are placed in mid-air as principles and primary concepts; . . . Therefore he who aims to penetrate such sciences must begin by instilling his mind with these grounds, a distasteful business for reason because it is asked to treat what is groundless as a valid foundation.[49]

It is precisely by virtue of the way in which logical representation opens the door to the inversion of immediate appearances into the content of the determination that political economy exhausts its role as science to engender its apologetic form as vulgar economics.

As for the return to the concrete by lifting simplifying assumptions, both Adam Smith and David Ricardo offer a particularly illustrative example in the aesthetically-naturalising form taken by their depiction of the transition from the 'early and rude state of society' to 'the accumulation of stock'. This transition is reduced to the substitution of the assumption that 'capital' belongs to the labourer for the more realistic one that 'all the implements necessary to kill the beaver and deer might belong to one class of men, and the labour employed in their destruction might be furnished by another class'.[50]

Dialectical reproduction: from '*Capital*' to the '*Grundrisse*'

Already before the *Grundrisse*, Marx had exposed the ultimate result of the analysis based on the construction of an abstract representation of the concrete by forcefully stripping it of its attributes: 'In consequence of thus abstracting all the so-called accidents, animate or inanimate, men or things, we are right in saying that in the final abstraction we have as substance the logical categories'.[51]

Even earlier, Marx had exposed the inversion inherent in all representation by which logic appears as the necessity that sets the concrete into motion, with the latter in turn conceived of under the appearance of being inert and therefore incapable of self-movement. Initially, he had limited himself to making a case for replacing a constructive necessity of a general nature with one that corresponded to the specificity of its concrete object: 'the proper logic of the proper object'.[52] However, later he advanced in the development of a scientific method capable of overcoming the externality of the constructive necessity *vis-à-vis* the real necessity of its object, making it clear that this externality was inherent in logic itself, no matter how concrete one might wish to make it: 'Logic is the

currency of the mind, the speculative *thought-value* of man and of nature, their essence which has become completely indifferent to all real determinateness and hence unreal, *alienated thought*, and therefore thought which abstracts from nature and from real man: *abstract* thought'.[53]

It might seem that, in the same text on the method in the *Grundrisse*, Marx is leaving room for a form of analysis guided by the search for a recurring attribute: 'As a rule, the most general abstractions arise only in the midst of the richest possible concrete development, where one thing appears as common to many, to all. Then it ceases to be thinkable in a particular form alone'.[54]

However, at stake in this passage is the condition of universal existence of the concrete that allows its abstraction to be thought up. In turn, the representation that starts out from an analysis based on repetition is the most immediate form of thought. Yet, precisely because of this it is unable to transcend the appearances of repetition itself. For example, freedom and equality can only be conceived of as abstract categories when they have become universal forms of the general social relation. However, despite this recurring presence, the latter says nothing about their content or, in other words, of their necessity: '[T]he stale argumentation of the degenerate economics of most recent times . . . *which demonstrates* that economic relations everywhere express *the same* simple determinants, and hence that they everywhere express the equality and freedom of the simple exchange of exchange values; this point entirely reduces itself to an infantile abstraction'.[55]

Now, the specific aim of this paper is to address the issue of method in the *Grundrisse*. However, let us recall the methodological observation made by Marx in the latter book itself: 'Human anatomy contains a key to the anatomy of the ape. The intimations of higher development among the subordinate animal species, however, can be understood only after the higher development is already known'.[56]

Thus, *pace* Mepham, let us thus begin by taking as the concrete object of our study of the dialectical method in the *Grundrisse* the fully-developed shape that it would acquire in *Capital*.[57]

The analysis pertaining to the dialectical method begins by confronting a determinate concrete. However, far from seeking out others alike to see what recurs in their manifestations, it attempts to uncover the necessity whose immediate self-realisation has taken the form of (hence determined) the original concrete. In other words, dialectical analysis penetrates the real concrete in search of the necessity that makes it what it is. It does so by separating the necessity in question in what it has as a pure potentiality, from its already realised result. The analysis thus separates the content of necessity (and hence, abstract existence) from its realised form (hence, concrete existence).[58] Once this first step has been made, the process must advance step-by-step towards the discovery of an ever simpler potential necessity. This is done by taking the content of the recently-discovered necessity as a concrete form in which its own necessity-content has in turn self-realised. In other words, the analysis moves forward by taking the abstract form uncovered in its determination as a concrete form itself.

---

[53] Marx 1992a, p. 383.
[54] Marx 1993, p. 104.
[55] Marx 1993, p. 249.
[56] Marx 1993, p. 105.
[57] Mepham also resorts to this same analogy to discuss the evolution of Marx's method from the *Grundrisse* to *Capital*, but to argue against its use as an appropriate way of approaching the question. In an Althusserian fashion, he thus postulates a 'radical discontinuity' between those two texts. See Mepham 1989, pp. 232–3.

In *Capital*, Marx makes evident how the analysis begins by facing the specific determination of the commodity as a social relation under the concrete form in which this determination presents itself, that is to say, under the form of exchange-value. He points out how, at first glance, it seems impossible that this concrete form is able to carry within itself a different content from its outward appearance.[59] However, this immediate appearance of exchange-value as an abstract quantitative relation dissolves as soon as it is analysed. In asking about the necessity for the existence of the quantitative relationship of equality between different use-values, it becomes clear that the latter immediately entails the existence of a common content. Let us note that what is at stake, here, is not the search for a recurring attribute, but the discovery of the source that allows each one of these two qualitatively different use-values indifferently to take the place of the other. Thus, such content cannot arise from the exchange-relation but, instead, must find expression within it.[60] The analysis continues by facing that common substance crystallised in the commodity in order to separate its realised form from its necessity as pure potentiality yet to be realised, that is to say, as the very action capable of engendering this common substance. At this point, the analysis faces the potentiality of human productive action, in other words, of labour, as the source of the commodity's exchangeability. Still, it discovers this potentiality only when taking a further step that abstracts labour from its concrete forms of realisation. This means it discovers that the necessity of value so far has the following as its simplest content: '[H]uman labour in the abstract. . . . [T]he same unsubstantial reality in each, a mere congelation of homogeneous human labour, of labour-power expended without regard to the mode of its expenditure'.[61]

---

[58] '. . . all science would be superfluous if the outward appearance and the essence of things directly coincided' (Marx 1966a, p. 817).

[59] Marx 1965, p. 36.

[60] Marx 1965, p. 37.

Now, the analysis cannot stop there. It has discovered abstract labour as the realised action that endows the commodity with value. However, inasmuch as abstract labour is itself a potentiality that has been realised, it appears to be devoid of all qualities except, precisely, its qualitative indifference. Thus, the analysis must search for the content of the necessity of abstract labour that produces commodities, which it finds in the material nature of abstract labour: 'Productive activity, if we leave out of sight its special form, viz., the useful character of the labour, is nothing but the expenditure of human labour-power. . . . [A] productive expenditure of human brains, nerves, and muscles . . . '.[62]

The analysis must now answer the following question: how can this material expenditure of human body, a condition of human life in general, be the determinant for the social specificity of the commodity? It thus continues by separating this materiality as an individual expenditure of labour-power from its necessity as an active organ of the process of social metabolism. Accordingly, the analysis discovers that this material expenditure has as its specific qualitative content the way in which the individual carrying it out rules his/her participation in the organisation of social labour. It is a productive expenditure of a human corporeality in general, which is made for others, whose concrete realisation is fully controlled by the will of the individual performing it. The commodity-producer controls by means of his or her own individual will how and what to produce for other members of society. Thus he or she consciously controls, free from personal dependence, the exercise of his or her individual capacity to perform social labour. At the same time, however, his or her consciousness is excluded from the organisation of the labour carried out by any other individual commodity-producer. There is no alien individual will, nor any collective will, organising the expenditure of the individual labour-power applied to the production of commodities. The labour that produces commodities is thus social labour privately undertaken by mutually independent producers: 'Only such products can become commodities with regard to each other, as result from different kinds of labour, each kind being carried on independently and for the account of private individuals'.[63]

---

[61] Marx 1965, p. 38.

[62] Marx 1965, p. 44.

[63] Marx 1965, p. 42. This translation obscures Marx's direct reference to 'mutually independent private labours' [*voneinander unabhängiger Privatarbeiten*] as the determinant of commodities. Nevertheless, the translations by E. and C. Paul and the one by Fowkes directly omit the word 'private'. Such an omission at this crucial point has prevented us from using them for our quotations. It is noteworthy how Marxist political economy has displaced the private form with which social labour is performed in capitalism as the specific determinant of the commodity-form. From this perspective, two main

The analysis that gives way to the reproduction of the concrete by means of thought does not end because the researcher arbitrarily decides to cease identifying recurring features in order to produce an even more abstract concept. Instead, it concludes, because when searching for the necessity of the recently-discovered content, it becomes plain that it can only be found by accompanying the self-realisation of that content in its necessary concrete form. Let us return to the case of the value-content of the commodity. Analysis has allowed us to discover that the commodity has value, that is to say, the attribute of exchangeability, because privately and independently performed socially necessary abstract labour has been materialised in it. This places us squarely in front of another question: why is it that this private and independent realisation of the material expenditure of human labour-power in general endows its product with the social attribute of value? The analysis, however, is unable to answer this question.[64]

In fact, if we examine the manner in which Marx presents how this point has been reached, the limit of the analysis appears as emerging from a change in its modality. Up to this point, it involved the search of the necessity of the content. Conversely, in its latest step, Marx presents it as if it were unable to penetrate through the exteriority of a recurring attribute, namely, that of being the product of private and independent labour. In other words, the analysis appears as having to assume the modality characteristic of the method of representation.

The question about the necessity of value now faces us in such a way that it can only be answered by accompanying the realisation of the specific potentiality that the analysis has discovered as an immanent actuality in the commodity. The commodity's exchangeability, posited by the materialisation of abstract socially necessary labour carried out in a private and independent manner, confronts us in the manner of a content that must account for its own necessity by realising it. Hence, the development must follow the movement of value in its necessary concrete form of expression as exchange-value.[65]

Marx thus successively unfolds the forms of the exchange-relation, asking each one in turn which content it progressively reveals. Let us note that this development does not imply a simpler form engendering a more concrete one. Instead, the unfolding of the former's necessity evidences the necessity of the

---

strands can be identified. The first one, principally based on the work of Sraffa, maintains that value is determined by the immediate material unity between social production and consumption, thus replacing private labour with one that is directly social as the foundation of the commodity-form. The second, which stems mainly from Rubin, holds that the specificity of commodity-producing labour is its 'abstract' character, which is defined in opposition to the materiality of abstract labour pointed out by Marx as a simple productive expenditure of the human body. On this issue, see Iñigo Carrera 2007, pp. 107–80.

[64] Marx 1965, p. 47.

[65] Marx 1965, pp. 47–8.

existence of the latter. The starting point from which to follow the development of the necessity of value to manifest in the concrete form of exchange-value is the simplest expression of the latter, namely, the exchange-relation between two different commodities: 'The whole mystery of the form of value lies hidden in this elementary form. Its analysis, therefore, is our real difficulty'.[66]

Already in this simplest form, it is clear that the value of a commodity, i.e. the socially-necessary abstract labour materialised in it in a private and independent form, does not only manifest itself in a purely relative manner. In addition, it does so necessarily through the use-value of another commodity that acts as its equivalent.[67] Above all, this first step in the process of unfolding of the value-content of the commodity in its necessary form as an exchange-value makes evident the same determinations already uncovered by the analysis:

> We see, then, all that our analysis of the value of commodities has already told us, is told us by the linen itself, so soon as it comes into communication with another commodity, the coat. Only it betrays its thoughts in that language with which alone it is familiar, the language of commodities. In order to tell us that its own value is created by labour in its abstract character of human labour, it says that the coat, in so far as it is worth as much as the linen, and therefore is value, consists of the same labour as the linen.[68]

Thus it might appear as if all that is at stake, now, is to present what the analysis has already discovered. Yet, we immediately discover that, in appropriating the 'language of commodities', that is, in reproducing in thought the commodity's immanent movement, certain determinations that the analysis was unable to discover now come to the fore. In first instance, the commodity affirms itself as the real subject whose development must be followed in thought: 'It therefore follows that the simple form of value of the commodity is at the same time the simple form of value of the product of labour, and also that the development of the commodity-form coincides with the development of the value-form'.[69]

The analysis could not account for the necessity of the commodity as its starting point. Matters are different as soon as thought begins to reproduce the movement of a commodity in its social relationship with another. In this second phase, the commodity shows itself as the necessary point of departure for the discovery of the concrete determinations of the specific form in which the materiality of the process of social metabolism in the capitalist mode of production is organised. The exposition here reflects the actual course of the research, which moves along a path alien to that of any analysis.

---

[66] Marx 1965, p. 48. With this statement, Marx brings out the specific difference between the representation and reproduction of the concrete. In the former, the key to the discovery of the law of determination lies in formal generalisation. By contrast, in the latter the key resides in the simplest expression of the content. See also Hegel 1999, p. 280.

[67] Marx 1965, p. 19.

[68] Marx 1965, p. 52.

[69] Marx 1990a, p. 67. We were forced to resort to this edition of *Capital* for this particular quotation because the edition we are normally using introduces here an alleged reference to the historical development of commodities that is completely absent from the German original.

In this ideal reproduction of the concrete, the research moves forward and uncovers the necessity according to which the general materiality of the labour represented in the value of the commodity appears in the very form of the exchange-relation.[70] At the same time, it reveals that the apparent absence of all unity in the materiality of the labour represented by value is the indirect form in which the general unity of the material process of social labour is realised.[71] Subsequently, it makes evident that this unity needs to acquire an expression that can synthesise it in the very movement of its own organisation, in other words, in the very movement of commodities.[72] In effect, in the exchange-relation, the corporeal materiality of any concrete form of the product of social labour mutates into that of the general equivalent as a synthetic expression of the indirect unity of social labour. This reveals that the unity of social labour is specifically established in capitalism on the basis of the general materiality of human labour, namely of the simple productive expenditure of the human body:

> The substance linen becomes the visible incarnation, the social chrysalis state of every kind of human labour.... In this manner the labour realised in the values of commodities is presented not only under its negative aspect, under which abstraction is made from every concrete form and useful property of actual work, but its own positive nature is made to reveal itself expressly. The general value form is the reduction of all kinds of actual labour to their common character of being human labour generally, of being the expenditure of human labour-power.[73]

We can now see that the reproduction of the necessity of the commodity in its realisation not only progresses by discovering determinations that the analysis was impotent to bring out. At the same time, it exposes the actual appearances to which it would have stuck had the research been interrupted at that stage. In the process of analysis, the unity of social labour expressed in the exchangeability of the commodity may appear, at first, as something determined by the absence of all material content in abstract labour. Only in a second step does the analysis inevitably face this materiality. By contrast, in the development of the value-form taken by the determination of the indirect unity of social labour, it becomes clear that such unity is predicated on the real material quality of abstract labour as a productive expenditure of human corporeality. This evidence comes up already in the simplest expression of value. In effect, the concrete labour that produced the equivalent can express the abstract labour that produced the commodity occupying the relative pole, only because its materiality as a simple expenditure of human labour-power is identical to that of the latter. As Marx points out, inasmuch as the analysis is the necessary first step in the scientific cognition of an actual concrete, it appears as easier to deal with, and even as sufficient, *vis-à-vis* the difficulty inherent in the second phase comprising the reproduction of the concrete in thought. Yet, it is only this second phase that has the power to account for the possible apparent abstractions that could have emerged in the course of the first, analytic phase: 'It is, in reality, much easier to discover by analysis the earthly core of the misty creations of religion, than, conversely, it is, to develop from the actual relations of life the corresponding celestialised forms of those relations. The latter method is the only materialistic, and therefore the only scientific one'.[74]

---

[70] Marx 1965, p. 63.
[71] Ibid.
[72] Marx 1965, p. 66.
[73] Marx 1965, p. 67.

The development of the value-form taken by the product of social labour performed privately and independently has shown us that, in the capitalist mode of production, the organisation of social production and consumption is not realised directly by consciously ruling the concrete material form taken by each individual labour. On the contrary, social labour achieves its unity indirectly, premised on the material identity of labour as human productive activity in general, that is, as labour whose materiality as the expenditure of human labour-power has not yet assumed a specific concrete form.[75] Thus, the unfolding of this form of organisation of the social labour-process cannot come to a halt without accounting for the necessary form in which it is borne in the consciousness of its subjects. Having arrived at this point, that which in the analytical stage could only be uncovered in a rather external fashion on the basis of mere repetition, is now exposed as emerging from the reproduction in thought of its own movement:

> [A]rticles of utility become commodities, only because they are products of the labour of private individuals or groups of individuals who carry on their work independently of each other. The sum total of the labour of all these private individuals forms the aggregate labour of society. Since the producers do not come into social contact with each other until they exchange their

---

[74] Marx 1965, pp. 372–3, n. 4.
[75] Marx 1965, p. 67.

> products, the specific social character of each producer's labour does not show itself except in the act of exchange. In other words, the labour of the individual asserts itself as a part of the labour of society, only by means of the relations which the act of exchange establishes directly between the products, and indirectly, through them, between the producers.[76]

In sum, the development of the form of value does not simply consist in the exposition of the determinations of value that were already discovered through analysis. On the contrary, only such a development is able to reveal that, when organising their social labour, the mutually-independent producers cannot rely on any social relation other than their general condition as individual bearers of the capacity to expend their bodies productively, in other words, to carry out labour in general. It is incumbent on each private producer to expend this generic capacity in a determined concrete form. In other words, each of them privately exerts his or her abstract labour in the form of a determined concrete labour. If this expenditure of labour-power has materialised under a socially-useful concrete form, the corresponding abstract labour will be represented as the social attribute of its product to establish an exchange-relation with another bearer of an identical objectification of abstract labour. The materiality of socially-necessary abstract labour is represented as the value of its product, which thus acquires the specific social determination of a commodity. The material unity of privately and independently undertaken social production is established in this indirect form. The value-form taken by commodities is the general social relation indirectly established by the mutually-free producers. This is the reason why the product of their own labour confronts them as the bearer of an alien social power that dominates them.

The scope of the dialectical method in the *Grundrisse*

Let us return to the *Grundrisse.* Already in these manuscripts, Marx reveals the historical specificity of the commodity as the general social relation in a society where social labour is organised privately and independently, which determines its producers as mutually-free persons:

> The dissolution of all products and activities into exchange-values presupposes the dissolution of all fixed personal (historic) relations of dependence in production, as well as the all-sided dependence of the producers on one another. Each individual's production is dependent on the production of all others; and the transformation of his product into the necessaries of his own life is

---

[76] Marx 1965, pp. 72–3. Again, Marx's direct attribution of the private character to labour, *Privatarbeiten*, becomes an attribute of the individuals in the translation.

> [similarly] dependent on the consumption of all others. . . . The reciprocal and all-sided dependence of individuals who are indifferent to one another forms their social connection. This social bond is expressed in *exchange-value*, by means of which alone each individual's own activity or his product becomes an activity and a product for him; he must produce a general product – *exchange-value*, . . . The individual carries his social power, as well as his bond with society, in his pocket. . . . Each individual possesses social power in the form of a thing. Rob the thing of this social power and you must give it to persons to exercise over persons.[77]

It might seem, then, that the difference in the development of the dialectical method mediating between the *Grundrisse* and *Capital* is limited to the greater wealth of detail with which the latter presents the same essential question already uncovered in the former (namely, the simplest form of the general social relation in a society of mutually-free individuals). However, as soon as we examine the path taken by Marx in the *Grundrisse*, we can see that the discovery of the determinations of value still follows an essentially analytical course. In fact, from a methodological viewpoint, the specific richness of this part of the *Grundrisse* among Marx's works lies in the fact that it gives transparency to the limits weighing on progress during the analytical phase. The argument in *Capital* overcomes these limitations in the flow of synthetic reproduction. As we shall see below, the primacy of the analytical course is reflected in the limits on the cognition of the substance of value and, hence, in the development of this substance into its necessary concrete forms.

In progressing analytically, Marx discovers in the *Grundrisse* that at stake in the determination of use-values as commodities is the organisation of the materiality of social labour. He also discovers that the unity of this materiality manifests itself indirectly through the circulation of commodities. Yet, he only comes to face the materiality of abstract labour under the external appearance of its opposite, as the total absence of all materiality:

> In becoming an exchange value, a product (or activity) is not only transformed into a definite quantitative relation, a relative number . . . but it must also at the same time be transformed qualitatively, be transposed into another element, so that both commodities become magnitudes of the same kind, of the same unit, i.e., commensurable. The commodity first has to be transposed into labour time, into something qualitatively different from itself (qualitatively different (1) because it is not labour time as labour time, but materialised labour time; labour time not in the form of motion, but at rest; not in the form of the process, but of the result; (2) because it is not the objectification of labour time

---

[77] Marx 1993, pp. 156–8.

> in general, which exists only as a conception (it is only a conception of labour separated from its quality, subject merely to quantitative variations), but rather the specific result of a specific, of a naturally specified, kind of labour which differs qualitatively from other kinds), in order then to be compared as a specific amount of labour time, as a certain magnitude of labour, with other amounts of labour time, other magnitudes of labour.[78]

The general social relation thus appears bereft of the simplest material content bestowed by its historical specificity. This means that Marx has not yet discovered that its movement originates in the unity of society's material capacity to undertake labour in general, in order to impose itself indirectly through the concrete material forms in which this capacity has been privately and independently exerted. Thus, its movement is presented as if it emerged from the abstractly-ideal nature assigned to its simplest specific content. With such content reduced to the condition of a mere representation, namely to an abstractly ideal construction, the development of its concrete forms by means of thought appears correspondingly inverted. Instead of responding to the fact that thought follows the real movement, it appears as if the movement of thought itself were conceptually engendering those concrete forms: 'The product becomes a commodity; the commodity becomes exchange-value; the exchange-value of the commodity is its immanent money-property; this, its money-property, separates itself from it in the form of money . . . '.[79]

Marx himself subjects his development to criticism, exposing its upside-down nature: 'It will be necessary later, before this question is dropped, to correct the idealist manner of the presentation, which makes it seem as if it were merely a matter of conceptual determinations and of the dialectic of these concepts. Above all in the case of the phrase: product (or activity) becomes commodity; commodity, exchange-value; exchange-value, money.'[80]

Let us leave aside any improvements in the exposition of what has already been uncovered in the *Grundrisse* to focus on the key to the qualitative leap in the dialectical development that mediates between its point of departure and that of the *Contribution*, and which would be fully completed later in *Capital*. This key lies in the discovery of the material quality of abstract labour as a generic productive expenditure of human labour-power, of the human body, of muscles, brain, and so on, which, inasmuch as it is performed privately and independently, becomes represented as the social attribute of its product. Such a discovery was made possible only by Marx's development of the form of value.

---

[78] Marx 1993, p. 143. The difficult path taken by the reproduction of the concrete by means of thought has a noticeable expression when, in the *Contribution*, Marx discovered for the first time the materiality of abstract labour as a simple productive expenditure of the human body while, at the same time, he was not yet able to fully separate this materiality from that corresponding to the material difference between simple and complex labour (Marx 1911, p. 24).

[79] Marx 1993, p. 147.

[80] Marx 1993, p. 151.

In turn, this development of the progress from the simplest determination of the commodity to its concrete forms impinges on the mode in which Marx undertakes the analysis. The latter no longer progresses from the immediate concrete to arrive at 'abstract or simple categories', as Marx still put it at the beginning of the *Grundrisse*. Instead, the analysis moves with the aim of discovering the simplest specific form of the immediate concrete. Hence: '[N]either "value" nor "exchange-value" are my subjects, but the commodity . . . [T]he simplest economic concretum'.[81]

Thus, the analysis does not merely move from the concrete to the abstract. More precisely, it penetrates the concrete itself until discovering the form constituting the simplest manifestation of its specific necessity. On the other hand, neither does the analysis progress by searching for the generic necessity in the apparent universal repetition of its manifestations. Hence, it can only reach the simplest concrete in its condition as a singular existence: '[T]he reader who wishes to follow me at all, must make up his mind to pass from the special [*einzelnen*] to the general [*allgemeinen*]'.[82]

Let us now summarise the issue by returning to the way in which Nicolaus reduces the development of the dialectical method from the *Grundrisse* to *Capital* to a difference between the mode of research, in the former, and the mode of presentation, in the latter. This reading overlooks the fact that the research is in full swing, and actually in its most powerful stage (hence able to overcome all appearance), in the development of the form of value unfolded in *Capital*. Nicolaus also argues, along with Reichelt, that the research-method is clearly visible in the *Grundrisse* but deliberately concealed in *Capital*. They thus overlook the fact that Marx resorts to a mode of exposition in *Capital* that at each step reveals the unity of the two moments inherent in dialectical research. Broadly put, he starts each presentational 'node' by facing what appears to be an immediate concrete in order to proceed to analyse its necessity. Once the latter is uncovered, he follows it through in its self-realisation until the initial concrete is reproduced but now as a *known* concrete. This does not mean that no change has occurred in the dialectical presentation between the *Grundrisse* and *Capital*. Specifically, Marx removed from the exposition the explicit reflections on the direction that the development of the content in its necessary form should take. However, those reflections are, strictly speaking, external to the ideal reproduction of the content's self-development. In light of his interpretation, Nicolaus recommends the following reading strategy in order to 'understand' Marx's method of research: firstly, the contemporary reader should approach the *Grundrisse*, then (in line with Lenin's aphorism) Hegel's *Logic*, and finally *Capital*.[83] The approach put forward in this chapter leads to very different implications. Thanks to the fact that Marx had to produce the *original knowledge* that progressed from the *Logic* to the *Grundrisse* and from the latter to *Capital*, we can empower our process of *recognition* by firstly appropriating the 'anatomy' (the method) of the most developed subject, namely, *Capital*. This more developed form of the critique of political economy contains the key to the understanding of the method of the *Grundrisse*, and the more primitive one of the *Logic*.

---

[81] Marx 2002, pp. 230, 242.

[82] Marx 1911, p. 9. In a more precise translation, *einzelnen* corresponds to the 'individual' and *allgemeinen* to the 'universal'. See Inwood 1992, p. 302.

Now, however inverted the sequence in search of the dialectical method may be presented, there will always be an abyss between the approaches just mentioned and Althusser's grotesque '*imperative* recommendation' (emphasis in the original) that *Capital*'s entire first section be skipped in order to avoid the 'highly damaging' 'Hegelian influence' which would prevent an understanding of 'what must be understood'.[84]

Once again concerning the point of departure . . . of working-class consciousness as revolutionary subject

We have discussed the substantive difference of form and content between the *reproduction* and the *representation* of the concrete by means of thought as methods of rational cognition. We have also seen how the *Grundrisse* are a step in the original development of the former, which only reaches the plenitude of its development in *Capital*.

However, still pending is the question of the change in the point of departure from the *Grundrisse* to the *Contribution*. We stated at the outset that the change should be traced in the very text of the former. We also claimed that in those earlier manuscripts the discovery of the determinations of the commodity as the simplest form of the general social relation in the capitalist mode of production was developed through an essentially analytical process. However, we should now add that, as Marx moves forward in the unfolding of the concrete forms taken by this general social relation, the unity of the text of the *Grundrisse* becomes increasingly determined by the stage of dialectical reproduction. This fact acquires its clearest expression at a crucial juncture much later in the text. Specifically, after unfolding the determinations of the capitalist mode of production in its concrete unity, the dialectical reproduction reaches the point at which it fully uncovers capital's necessity to supersede itself in the conscious organisation of social life. The analysis is, at this point, incapable of uncovering the necessity at stake, as all that matters in the existing concrete is its immanent potentiality to affirm through its own negation as the general social relation. In the face of this, the analysis is unable to go beyond the presentation of that potentiality as deprived of its own concrete content, conceiving it under the form of a 'recipe . . . for the cook-shops of the future'.[85] In reproducing in thought the determinations of the capitalist mode of production in their unity as constituting the existing concrete, Marx makes it evident that the historical necessity of this mode of production stems from the specific form in which it radically transforms the materiality of the worker's productive activity through the socialisation of private labour:

---

[83] Nicolaus 1993, p. 60.

[84] Althusser 1971, p. 93.

> The exchange of living labour for objectified labour – i.e. the positing of social labour in the form of the contradiction of capital and wage labour – is the ultimate development of the *value-relation* and of production resting on value . . . No longer does the worker insert a modified natural thing [*Naturgegenstand*] as middle link between the object [*Objekt*] and himself; rather, he inserts the process of nature, transformed into an industrial process, as a means between himself and inorganic nature, mastering it. He steps to the side of the production process instead of being its chief actor. In this transformation, it is neither the direct human labour he himself performs, nor the time during which he works, but rather the appropriation of his own general productive power, his understanding of nature and his mastery over it by virtue of his presence as a social body – it is, in a word, the development of the social individual which appears as the great foundation-stone of production and of wealth. . . . Capital itself is the moving contradiction . . . On the one side, then, it calls to life all the powers of science and of nature, as of social combination and of social intercourse, in order to make the creation of wealth independent (relatively) of the labour time employed on it. On the other side, it wants to use labour time as the measuring rod for the giant social forces thereby created, and to confine them within the limits required to maintain the already created value as value. Forces of production and social relations – two different sides of the development of the social individual – appear to capital as mere means, and are merely means for it to produce on its limited foundation. In fact, however, they are the material conditions to blow this foundation sky-high.[86]

---

[85] Marx 1965, p. 17.

[86] Marx 1993, pp. 704–6.

Almost immediately after thus discovering the concrete historical determination of the capitalist mode of production, Marx confronts again the commodity and its value-determinations in the *Grundrisse*. Yet, this is no longer something abstractly analytic. Following the simple note 'this section to be brought forward',[87] Marx begins to unfold the determinations of the commodity as the simplest concrete form of the general social relation in this mode of production. However, having barely begun this development, those earlier manuscripts break off. The body of their text has given way to what would be the 1859 *Contribution*. Nevertheless, it is the 1857–8 version of Marx's critique of political economy that has brought to light that the development of the reproduction of the concrete by means of thought (rather than the analysis) is what determines the necessity of the point of departure.

Now, how has the starting point concretely changed? At the outset of the *Grundrisse*, Marx posited that the point of departure was 'individuals producing in society' while in the *Contribution* and *Capital*, this becomes 'the commodity'. Let us take the 'individuals producing in society'. The first step that these individuals need to make to undertake their social production consists in organising it: that is, each of them must be assigned with a useful concrete labour to be performed for others. The mode in which they unfold this organisation is but the exercise of their general social relation at the point at which each cycle of society's life-process is set into motion. Thus, the point of departure in the study of the 'individuals producing in society' is that of the simplest specific form presented by their general social relationship in each historical period. What is this form in the capitalist mode of production? It is not a direct social relation between persons. Conversely, it is an indirect relation that they establish through the exchange of the products of their privately and independently-undertaken social labour as materialisations of equivalent quantities of abstract labour. In brief, that social relation is the commodity. The *Contribution* and *Capital* both begin from exactly the same point that Marx had been propounding as the necessary one until then. However, his progress in the reproduction of the concrete by means of thought allows him to recognise that this thing, the commodity, is the simplest concrete form bearing the capacity to organise social labour – and hence social consumption – in a society where individuals are free of personal dependence. The full conscious control over one's own individual labour corresponding to its private and independent realisation entails, at the same time, the complete lack of conscious control over its social character. Hence the subordination of the human individual to the social powers objectified in the product of his or her own labour.

---

[87] Marx 1993, p. 881.

Let us look once again at the question of method. Logical representation is not the *natural* form of scientific method. As all forms of consciousness, and hence of the human capacity to organise action, scientific method is itself a historically-determined social form. Against this form of consciousness stands the reproduction of the concrete by means of thought, also as the bearer of a historically-determined social relation. Marx developed the historical necessity of this method, 'in its essence critical and revolutionary', as the necessary form of consciousness in the supersession of the capitalist mode of production. Yet it subsequently fell into oblivion, nearly to the point of being forgotten altogether, or rather erased, even by Marxist scholars themselves. The aim of this text is to put the question back at the heart of the discussion of the form of working-class consciousness with the power to organise capital-transcending practice.

From the Materiality of Labor to the Political Strength of the Working Class

Juan Iñigo-Carrera
Centro para la Investigación como Crítica Práctica – CICP
juanbinigo@gmail.com

At the beginning of the *Grundrisse* Marx discovers commodities as the objectified form of our general social relation. He immediately points out that the historical role of the capitalist mode of production is to engender, "for the first time", through "personal independence founded on objective dependence", "a system of general social metabolism, of universal relations, of universal needs and universal capacities", as a condition for a following stage of "free individuality based on the universal development of individuals and on their subordination of their communal, social productivity as their social wealth".

By the beginning of the 1970s it seemed that the accumulation of capital was advancing in this direction, through the development of public education, public health, the centralization of capital as state property, the processes of national and social liberation, etc. All of these developments took form through the strength of the political and union organizations of the working class. It even seemed that superseding capitalism was just a matter of developing a revolutionary consciousness able to take power. Ten years later, all of these processes were pointing backwards: privatizations, deep differentiations in the selling of labor power, multiplied unemployment, the advance of finance over production, etc. All of these changes took shape through the retreat of the unions and the political parties of the working class, who visibly lost their power, or even worst, they just became neoliberals. So much so, that claiming that the point is to change the world without taking power could be seen as the non plus ultra of a revolutionary consciousness.

Such a reversion in the basis of the accumulation of capital is frequently explained as a matter of the capitalist class' political will to discipline the working class, or even as a matter of its revenge upon the working class. But we must recall that it is not consciousness which determines social being, but concrete social being which determines, i.e. takes concrete shape in, consciousness. Therefore, from a materialist point of view, we must search for the roots of these changes in political power starting from the very materiality of the process of social production and its consequential modes of organization.

Presentation at the 7th Annual Conference in Political Economy: International Trends and National Differences, International Initiative for Promoting Political Economy, ISEG / 7-9 2016, Lisbon, Portugal.

Up to the 70s, the production of relative surplus value through the system of machinery hold at its core two processes of manual labor: the calibration of machinery and the assembly line. To this technical basis corresponded the production of relatively undifferentiated workers. Consequently, individual capitals profited from the reproduction of labor power in large scale through the direct action of the state.

But the production of relative surplus value through the system of machinery has the technical necessity to remove all manual labor from the flow of production. And by the early 80s computing matured to the point of allowing the substitution of manual skills through the automation of machinery and robotized assembly line. Consequently, capital's needs for labor power radically change: now, on the one hand, it needs workers bearing a constantly developed productive subjectivity related with intellectual labor and, on the other hand, workers with practically no skills to operate as appendix of the machinery and in manual labor. The new international division of labor is the main form in which the process of capital accumulation in its global unity developed this differentiation. In brief, the classical countries that produced the generality of the commodities they consumed left place to some countries specialized in complex labor, and other countries specialized in simple unskilled labor. From the old international division of labor only rest the countries specialized in the production of raw materials. Beyond these three broad types of countries, remain those that mainly became reservoirs of laboring surplus population. In the first type of countries, immigration became the source of cheap labor power for the processes of production that require it. Now, the access to education, health, housing, etc. ceased to be based on citizenship, to become an attribute of individual wages. Meanwhile the centralization of capital flowed beyond the range of national states.

Consequently, the development of the capitalist mode of production is currently taking a concrete form opposite to its general historical determination as the condition for the production of universal individuals bearing universal capacities and universal needs. This is a critical matter for the political organization of the working class. The central question is how to develop the mutual recognition as historical subjects between the workers that perform the more complex labor and those who perform unskilled labor, and, moreover, between both types of active workers and the increasing mass of consolidated relative laboring surplus population. This very same question crosses the national boundaries. Yet, these questions are far from being at the core of the political organizations of the working class today. On the contrary, we are witnessing a trend towards an increased antagonism between the members of the working class determined by capital in those three different ways, mediated at the same time through their international competition. The surge of nationalism, xenophobia, racism, warmongering, religion, are expressions in this sense.

In turn, the process of general overproduction currently suffered by the global accumulation of capital (once and again extended through the expansion of insolvent credit and the issuing of money to the point of creating the appearance that finance has become the true source of capital accumulation) deepens the antagonism.

Moreover, the working class faces a further technical transformation that will deepen the differentiation in the conditions for its reproduction. The production of relative surplus value points now to a greater elimination of manual workers and of workers as appendixes of the machinery at the shop-floor, however cheap their labor power could be.

All this evidences confront us with a question that roots the revolutionary organization of the working class. A widespread point of view aims to base this organization on the conception of freedom as a natural condition inherent to human beings, which suffers from mutilation under capitalism. But let us return to our starting point: let us face the existence for the first time in history of a system of "personal independence founded on objective dependence" whose historical necessity is to engender the concrete material conditions for "free individuality based on the universal development of individuals". Thus faced, it becomes evident that human freedom is not a natural condition but a historical form of social relation specifically inherent to this mode of production. It becomes evident that, as historical concrete human subjects, that is to say, as members of the working class, our freedom from personal dependency is the form taken by our submission to our objectified general social relation, to capital. As Marx puts it in *Capital*: "From a social point of view … the working class, even when not directly engaged in the labor process, is just as much an appendage of capital as the ordinary instruments of labor. Even its individual consumption is … a mere factor in the process of production". But, at the same time, it becomes evident that capital is an objectified social relation that bears in itself the necessity to produce its own supersession into a society of free individuality based on the universal development of individuals. This contradiction is what determines the working class as a revolutionary subject. The political freedom of the working class to supersede the capitalist mode of production is the necessary concrete historical form taken by the development of its alienation in capital. In other words, from this contradiction arise the historical powers of the working class. But, at the same time, it is this same contradiction which takes concrete form in the antagonistic relations within the working class itself. In order to advance determining itself as a consciousness that points towards the "universal development of individuals", the political organization of the working class as a revolutionary subject needs to start by recognizing itself in its contradictory determination of being a free action that carries in itself the movement of alienation. The recognition of this concrete determination of the working class' subjectivity, is a necessary first step in the political organization of the working class able to engender its universal solidarity.

In brief: the political organization of the working class as a revolutionary subject is not a matter of the affirmation of abstract naturalized freedom. It is a matter of a freedom that affirms itself through the negation of its own alienated content and, therefore, a matter of the negation of the negation of freedom as it is historically determined as a specific social relation of the capitalist mode of production.

Being a Marxist or objectively recognizing one's own political subjectivity through the dialectical method discovered by Marx[1]

Juan Iñigo Carrera

CICP

1) On Marxism's interpretive character, or on the objectively unsolvable dichotomy between 'true' and 'false' Marxism.

'Where is the party in opposition that has not been decried as communistic by its opponents in power? Where is the opposition that has not hurled back the branding reproach of communism, against the more advanced opposition parties, as well as against its reactionary adversaries?'.[2]

There is no reason to think that, on writing the passage above, it would have crossed its authors' minds that, in the course of history, the term 'Marxist' would replace that of 'Communist' in this mutually incriminatory usage between governing and opposition parties. Moreover, such an indictment gets an immediate response from the incriminated party; 'Marxist!', says one; 'No, Keynesian!' replies the other. 'Marxist!' reciprocates the accused party as soon as it emerges that a major leader of its opponent has a Communist skeleton hidden in the cupboard. 'If you are not a Socialist at twenty, you have no heart, but if you remain one at thirty, you have no head!' substantiates the other, paraphrasing Clemenceau. Nonetheless, however amusing this tragicomic exchange of recriminations may be, in which a sort of 'Who, me?' attitude prevails, it is a seemingly opposite discussion that is of real interest from the point of view of the political action of the working class. In this discussion each one proclaims him/herself Marxist at the same time that, usually, accuses as "false Marxists" those who also proclaim themselves Marxists but disagree on the interpretation of the point at stake. The question becomes inevitable: What do those who consider themselves Marxists understand by being Marxist?

It is usual practice in this milieu to confidently place the phrase 'According to Marx's theory…' before any personal judgement, and to virulently expell any dissenter from 'the realm of Marxism'. Even Pio IX would have envied such expressions of dogmatic infallibility. However, unlike his case, there has never been among Marxists any conciliar agreement that would anointed one Pope. The world of Marxists is not made in image and likeness of the world of commodities, in which the latter have sellected one as the expression of their value-quality. It is, so to speak, a world of plain and simple commodities. Therefore, the dogmatic authority of one Marxist can be called into question by all others. At least outside party and academic hierarchies.

In the absence of a universaly accepted authority who could dictate what constitutes 'true' Marxism, no objective resolution can be found to the debate on who can legitimately be defined as Marxist, which leads to the permanent renewal of the argument. Recently, Professor Rolando Astarita has proposed what he considers an unsurpassable criterion to settle the issue of classification.[3] According to him, it is a criterion based on 'the dialectical idea of a leap from quantity into quality'. Thus, he singles out as mere 'quantitative variations' 'a range of nuances and disagreements with aspects of the theory, however maintaining the core beliefs that form a theoretical and political body with definite characteristics'. Beyond these quantitative variations, 'there are challenges which involve a qualititative break'. The autor presents, as an example, that of the theory of exploitation, which, 'being (…) one of the defining features of Marxism, the proposition that the capitalist mode of production is not exploitative would not fit, by any means, within the Marxist current of thought.'

---

[1] A previous version was presented at the VII Jornadas de Economía Crítica in 2014

[2] Marx, Karl and Engels, Friedrich [1848], 'Manifesto of the Communist Party', *Marx/Engels Selected Works*, Vol. 1, Progress Publishers, Moscow, 1969, p. 98.

In line with this criterion, it seems plain to exclude from the Marxist realm someone who states that '[a]ll legitimate income, from work or not, should be protected',[4] which in other words means to consider income obtained from exploiting others' work as legitimate. Yet, this statement is a fundamental principle of 'Marxism-Leninism, Mao Zedong Thought and Deng Xiaoping Theory' for those who rule their practice by 'the important thought of Three Represents'.[5] And precisely given that the 'leap from quantity into quality' has been invoked, a question arises: Would it make sense to exclude from Marxism those who probably comprise the largest number of people that define themselves as Marxists worldwide?

Let us consider another case. Following the cited argument, the conception that 'capitalism suffers from unnecessary alienation and exploitation', whose necessity of being transcended 'flows from a historical world view, based on the evolution of forms of property',[6] apparently does not infringe the boundaries of a 'quantitative variation'. Yet if the limit to the 'qualitative break' is premised on the endorsement of Marx's theory of value, then Roemer's 'analytical Marxism' should clearly remain off-limits, insofar as it rejects it for the analysis of exchange relations. Instead, he states that for such analysis 'the tools *par excellence* are rational choice models: general equilibrium theory, game theory, and the arsenal of modelling thechnics developed by neo-classical economics'.[7] However, no Marxist within the range of quantitative adequacy has yet succeded in precluding 'analytical Marxism' from being considered a variety of Marxism.

Likewise, a stricter stance could be adopted towards the 'every man his own Marxist' view,[8] considering that a 'simultaneous dual-system interpretation' in the derivation of production prices from values rejects Marx's theory of exploitation, as opposed to a 'temporal single-system interpretation'.[9] And how to esablish if the *Neue Marx-Lektüre*'s critique of the tendency of the rate of profit to fall is just a 'quantitative variation' or exceeds the limits of a 'qualitative break' from Marxism.[10] Or if the new category of a 'Marxism without Marx' is at all plausible within it.[11] Or if only those who propose to 'return to Marx' in order to fight 'religious Marxism'[12] are worthy of holding the name -which would imply that to be a real Marxist, one should first have gone somewhere else from where to return. Or if, after all, even the modern emulators of Proudhon could feel welcome by the 'we are all Marxists now'.[13] In sum, how to establish on which side of the dividing line drawn for the 'leap from quantity into quality' an 'erratic Marxist',[14] a 'Marxist for the long run and Keynesian for the here and now',[15] or the statement itself that 'to take 'liberties' with the signature of Marx is in this sense merely to enter into the freedom of Marxism',[16] should be placed.

In turn, Marx himself has been declared unworthy of being reclaimed as a Marxist, as he is said to have professed 'the ideological, non-scientific character of the concept of'alienated labour' -and thus of the concept of 'alienation' that supports it',[17] which leaves a 'flagrant and extremely harmful […]' influence: 'the theory of *fetishism*'.[18] He has also been accused by the Marxist Rubin of infringing upon the interpretation of his own theory, for having 'a few sentences' in which he brings out the materiality of abstract labor common to all forms of social organization, and which is socially represented as the value of commodities only when it is performed in a private and independent manner, something that 'cannot in any way be made consistent with the entirety of Marx's theory of value'.[19] Nevertheless there are also those who furiously blame Marx himself for the generosity thanks to which anyone can be considered a Marxist: 'We are all Marxists in a Marxian world'.[20]

The criterion presumably based on the 'dialectical idea of a "leap from quantity into quality"' thus proves helpless for establishing the contours of Marxism, other than by lapsing into an arbitrary subjective rule based on the maxim: 'I, true Marxist; you, false Marxist'. And this inability to avoid aribitrary criteria should come as no surpirse. In effect, the difficulty invovled in any sort of classification resides in explaining the nature of the qualitative difference that manifests itself in a quantitative difference, instead of proceeding blindly in reverse, that is, by starting from the observation of an alleged quantitative difference in order to derive from it the existence of a qualitative difference whose content remains unexplained. This inverted approach, which proceedes by leaving the quality undefined, cannot surpass the barrier of *smallness* in the difference.[21] In this case, this means the barrier of the sectarian debate on who is and who is not included.

Given that the starting point of any classification is the recognition of the qualitative attribute that determines its object, the problem faced is the qualitative definition of what is being Marxist. And the distinctive qualitative attribute that all Marxists share is that they all self-identify as individuals who seek to interpret Marx's writings, and more generally his action, in the positive manner that each of them conceives as adequate. Yet it is not an interpretation which is sought out of scholastic interest. Instead, it is aimed at being applied to the real world in order to interpret its workings in a way that allows the transformation of the existing social order into one which is superior from the point of view of the realisation of the human species being.[22] To sum up, *the qualitative attribute that defines Marxists is the self-recognition as political subjects intending to interpret the world in order to change it, by interpreting Marx in the positive way they concibe as appriopriate*. And this qualitative attribute remains unchanged, regardless of the claim to be doing a *Marxian* interpretation as opposed to any *Marxist* one, whereby 'Marxian' is seen as 'Marx's own'.[23]

The question about the qualitative nature of Marxism leads us to the question of what is the qualitative nature of '*to interpret*'. All interpretation is an action in which the subject defines which of the attributes that his/her determinate subjectivity makes him/her discover in the object, are relevant in the determination of the latter's very objectivity and, consequently, of its potientialities. On this basis, the subject thereby confronts the object as if it embodied as its actual necessity that which had been ideally introduced in it by his/her own subjectivity. In other words, the object becomes represented under the appearance of possessing that subjectively-constructed necessity. Whether the interpretation is of a music score, religious texts or -what is our concern- the scientific writings of Marx, such is the subjectively determined essence of interpretation.

Given the interpretive character of Marxism, i.e., given that Marxists define themselves as interpreters of Marx, the fact that they interpet Marx in various ways determines them as different species within the same genus. The plausibility of 'each one their own Marxist' is inherent in the very interpretive essence of Marxism. Hence, it also follows the impossibility of finding an objective criterion capable of drawing the line between 'true' and 'false' Marxists. *The attempt to establish such objective criterion is a contradiction in terms in the face of the interpretive essence of Marxism.* This finding obviously cannot by itself put an end to the mutual accusations of 'false Marxist'. On the contrary, its power resides in explaining why such recriminations have formed, and will continue to form, part of the Marxist subjectivity.

2) Knowledge is the organizational instance of action, or to know is to organize one's own action

Well-known are Engels's citations of Marx's remarks about himself: '…Marx once said to Lafargue: "*Ce qu'il y a de certain c'est que moi, je ne suis pas Marxiste*"'.[24] In addition, 'As Marx said of the French Marxists in the late seventies: *"Tout ce que je*

---

[22] Gattungswesen, strictly, but unusual in English, generic being.

[23] '*Marxist* theory of value necessarily blocked the understanding of the *Marxian* theory of value'. The interpretative contrast between Marxist and Marxian is widely spread, to the point of thus citing Hans-Georg Backhaus's statement from his *Dialektik der Wertform*, Freiburg, Ca iraVerlag, 1997, p. 69, in the Spanish translation of the text from Elbe, Ingo, *Marx im Westen*, Berlin, Akademie Verlag, 2010, http://enelhorizontedelacrisis.files.wordpress.com/2013/01/ingo-elbe_entre-marx-el-marxismo-y-los-marxismos.pdf . Yet the original uses the term *Marxschen*, which strictly means, 'by Marx'.

[24] Engels, Frederick, 'Engels to E. Bernstein, 2/3 November 1882', *Marx-Engels Collected Works*, Volume 46, Great Britain, Lawrence & Wishart, 1992, p. 356.

sais, c'est que je ne suis pas Marxist"'.[25] And directly in German, 'Marx said: "All I know is that I'm not a Marxist"'.[26]

Were the point to interpret Marx, it could be concluded that his own self-exclusion from Marxism responds only to a formal impossibility: Marxism can interpret Marx, but it would be meaningless to say Marx interprets himself. Alternatively, it could be understood as an expression of Marx's irony.[27] Or a 'pained lament' in rejection of Lafargue and his followers' doctrinary conceptions.[28] Or else, as a means of 'getting rid of' an 'aberrant mythology' about the '"creators" of a set of ideological conceptions artificially grouped under the name of "Marxism"', which carries the stigma of 'obscurantism from its origin'.[29]

The speculation on how to interpret Marx's reasons to explicitly reject being a Marxist can go on endessly. But what does the interpretative character of Marxism really mean from the point of view of our own condition as political subjects willing to take action to change the current social organization? At once, another passage from Marx that focuses on the the nature of interpretation springs to mind: 'The philosophers have only *interpreted* the world in various ways. The point is to *change* it'.[30]

There is a general agreement among Marxists as to the interpretation of this statement: philosophers are not being criticized for interpreting the world, but for thereafter not acting upon it . In other words, according to this view the point is to interpret the world in order to act on its change on the basis of that interpretation. Nevertheless, let us examine again the nature of an interpretation. Whatever the particular object under consideration, to interpret something is a mode of knowing the potientiality that such object embodies in order for the subject to appropriate it. Interpretation is thus is a form of knowledge. Consequently, in order to resolve the question of the necessity of interpretation as such, we should first inquire into the necessity of knowledge in general.

In any metabolic process, the subject needs to expend its body in order to appropriate objects from its environment, thereby reproducing itself as a subject. The production of knowledge is the moment of this metabolic process in which the subject consumes its body in order to appropriate its own potientiality faced with that offered by the object from its environment. That is, knowledge is the moment of the subject's self-reproduction process by which it virtually appropriates its condition as such subject in order to regulate the full expenditure of its body that is needed to effectivelly act upon, and thereby actually appropriate, the object. Hence, knowledge is the process by which the subject organises its own action of effectively appropriating the object in order to satisfy its own purpose. In this condition as a moment of the subject's bodily expenditure in order to organise its action, knowledge is an inner instance of this action itself, the action in its own unfolding. Therefore, the point is not that the philosophers stopped short of acting once they have intepreted the world. The point lies in the fact that the very form of their knowledge of the world, the fact that they interpret it, has been the necessary form of ruling their action in a manner which makes it impotent to change the world. The question we are facing here does not refer to the content of the interpretation but to the very form of the process of knowledge that results in an iterpretation. In other words, it refers to to the method of this knowledge.

Conscious knowledge, i.e. a kind of knowledge which knows itself as such -or more simply, *consciousness*- is the form of knowledge generically inherent to human beings. Consciousness is the way each human being carries in his/her person the capacity to rule his/her own individual action as an organ of the process of social metabolism.

Scientific consciousness, or scientifc knowledge, is a specifically determined form in which the human subject rules his/her action upon the object. Under this specific modality, the subject aims to virtually appropriate his/her own potientiality faced with that of the object without allowing, in this process, his/her own subjectivity to posit -whether ideally or actually- determinations in the object which are alien to it. Accordingly, it is a form of knowledge through which the subject aims to ideally aprehend the determinations of his/her own subjectivity, as if the latter were an external object itself. Its method, i.e. its form, thus has a twofold objective character. Hence its power to transform reality.

A question arises here as to why, if scientific knowledge is in itself but an inner moment of the self-organisation of human action in the manner most powerful for changing the world, is it conceived in contemporary society as sundered from action: on one hand, there is theory; on the other, practice. At most, the positing of that constitutive separation between theory and practice is then followed by the claim that both should be placed in a correspondingly external relationship whose concrete form can never be clearly defined. In fact, this divorce between scientific knowledge and action underlies the Marxist interpretation which submits that the problem with philosophers is that they know but do not act thereafter.

3) The scientific method of logical representation as a historically specific social relationship, or free scientific consciousness as a form of alienated consciousness in capital.[31]

In the capitalist mode of production, consciousness is determined in a historically specific way. The general social relation, hence one's own social being, confronts individuals as an objectified existence external to their person. This objectified social relation, which is the product of privately-performed social labour, carries the power to set into motion social labour itself with no immediate goal other than its self-multiplication. Such is capital's generic determination. Thus, human subjects are free from relations of personal dependence in the organization of their lives because they are subordinated to the social powers objectified in capital. To put it briefly, free consciousness is the form taken by consciousness alienated in capital.[32]

Capital's need for scientific knowledge embodies a contradiction. In order to produce relative surplus value through the system of machinery, capital needs to subordinate production to science. However, inasmuch as scientific knowledge is simply a specific form of the production of surplus value, science has to reproduce the alienation of consciousness in capital.While it must be an objective consciousness, it must also confront itself in a non-objective way, falling prey to the appearance of being an abstractly free consciousness. Therefore, it is a science that needs to present the foundations of its objectivity as originating from outside itself, more specifically, as founded on a philosophical representation that is conceived as emerging from a pure abstractly free subjectivity.

---

[31] Henceforward, this text is based on the chapter named 'Dialectic method. Critique of scientific theory', by Iñigo Carrera, Juan, *El capital: razón histórica, sujeto revolucionario y conciencia* [*Capital: Historical Reason, Revolutionary Subject and Consciousness*], Buenos Aires, Imago Mundi, 2008.

[32] See also Iñigo Carrera, Juan, Conocer el capital hoy. Usar críticamente "El capital", [Knowing capital today. Using 'Capital' critically], Buenos Aires, Imago Mundi, 2007, pp. 55-62.

Logical representation is this contradiction resolved, i.e. developed. It represents real connections by taking the forms in which the determinant necessity appears as already realized, as if they did not simulataneously embody a necessity of their own to be realized. On this basis, real existences are defined as incapable of self-movement. Thus, nothing in the real world is conceived as being able to bear within itself the need -i.e. to be the subject- of its own trascendence. It seems that all movement must be bestowed upon them externally. Thus posited as incapable of self-movement, all real forms are represented in thought as if they were abstract immediate affirmations. In this way, free consciousness can only be free consciousness. Likewise, alienated consciousness can be nothing but itself. But there is no way in which free consciousness could be a concrete form of alieanted consciousness. At most, according to so-called dialectical representation, both can be put together contradicting each other externally, albeit each one of them as its correspondingly abstract immediate affirmation.

Once real existences are devoid of their necessity, i.e. turned into concepts, the representation of their motion must impose upon them a constructive necessity that relates them externally in thought, so as to build a conceptual system. However, as a means to scientific knowledge, this constructive necessity must represent the outward manifestation of the objective relationships among its objects. The systematization of the said constructive necessity is the logic of representation. The appearance as immediate abstract affirmations effectively corresponds to the expression of the real quantitative determination considered in itself. On this basis, the logical construction starts conceiving of concrete forms as devoid of a necessity to be realized, thereafter representing that necessity through the relations of measure observed among them. Although the very quality of the necessity at stake remains unknown, it is still possible to act upon the relations of measure among such forms, thereby modifying quantities until they correspond to a different qualitative form. Here lies the power of logical representation to transform the existing material conditions as a historical specific form of developing the productive forces of society ruled by the production of relative surplus value. It can measure everything objectively, without inquiring on the objective necessity of anything. In particular, without inquiring on the objective necessity of the knowing subject's own subjectivity.

Nonetheless, the very form of this logical representation does not just hinder the possibility of discovering that the progress in freedom implied in the capacity for action that this mode of knowledge confers, is the necessary form in which alienation self-develops. Its power in this respect takes a concrete form which is of particular interest here. Logical representation starts by conceiving of real concrete forms as abstract immediate affirmations. Therefore, the real necessity that determines them can only be grasped by representation through the greater or smaller degree of recurrence in which such real concrete forms appeared at the beginning. Hence, logical representation itself reaches a logically inevitable conclusion: by virtue of its own constructive character, which is necessarily external to the real necessity which it attempts to appropriate by means of thought, logical representation makes it impossible to attain any certainty of an objective knowledge before acting. Consequently, the conclusion is drawn that logical representations, hence scientific theories, are indeed different ways of interpreting reality. They are but ideological constructions. And this eventually culminates in the the view according to which the claim that all scientific knowledge is ideologicaly determined by its very nature, is seen as the most genuine expression of a critical consciousness, historically able to overcome its current form.

Such conclusion, stemming from the very form of logical representation whatever its content may be, is not an abstract epistemological question but concretely concerns working class political action. It entails the naturalization of the capitalist mode of production and, thus, a way of depriving the working class of its condition as revolutionary subject. Any interpretation of a real determination is, in itself, the negation of a knowledge that has trascended all appearance. The interpretation of the determination of one's social being is the negation of its full objective knowledge. Yet the full objective knowledge of the human being's determination as an individual organ of the social life process, born by the consciousness of each member of society, is the necessary form taken by the general social relation in a society founded on the general conscious organization of that process. Thus, the claim that objective knowledge is bound to remain an interpretation renders the general conscious organization of social life impossible. In other words, the claim that logical representation is the natural, therefore insurmountable form of scientific knowledge necessarily implies that the supersession of the capitalist mode of production by socialism/communism is impossible. So it is. By its very form -i.e., its method- logical representation is a form of objective consciousness proclaiming 'the end of History'.

Besides agreeing that the point is to interpret the world by positively interpreting Marx in order to change it, Marxists unanimously coincide that all social relations are of a historical nature. Now, we have already stated that consciousness is the form in which each human subject carries in him/herself the capacity to organize his/her own individual action as an organ of the process of social metabolism. Therefore, consciousness is the form in which each person carries his/her general social relation. In short, consciousness is a form of the general social relation. But it is not so abstractly, simply by virtue of its content. Its very form -i.e., its method- is an expression of the general social relation. Therefore, its method is a historical social product itself. According to Marxists, however, all general social relations might be historical, but not quite so the method of scientific knowledge, which is seen as naturally taking the form of logical representation and, in that condition, as one or another way of interpreting the world.

So much so that even someone who asserts that '[concerning Marxism] orthodoxy refers exclusively to *method*',[33] and that 'to grade the methods objectively in terms of their value to knowledge is itself a social and historical problem',[34] cannot find any specific about historical materialism, as regards the very form of representation, other than an abstract reference to a 'mediated totality'.[35]

---

[33] Lukács, Georg, *History and Class Consciousness*, Cambridge MA., The MIT Press, 1971, p. 1. Notably the English translation does not include the direct reference to Marxism present in the original edition, included here between straight brackets.

[34] Lukács, Georg, op. cit., p. 164.

[35] Lukács, Georg, op. cit., p. 164. In this manner, Lukács considers that '(t)he goal of these arguments is an *interpretation*, an exposition of Marx's theory *as Marx understood it*' (ibid., p. xliii). On the one hand, he clings to the appearance that 'theory' -i.e., the organizational moment of an action based on logical representation- may have an existence and finality abstracted from that action itself. On the other, that there can be a 'practice' devoid of the concretely determined integrity of its own organization. Subsequently, 'theory' and 'practice' are placed in a relationship of 'correspondence' (or lack of it) out of their mutual exteriority. Only in this way can an action in which the subject affirms his/her concretely

Nevertheless, logical representation is not the *natural* form of scientific method. It is a historically determined form of social relationship in which ideology, thus the negation of objective knowledge, becomes affirmed under the appearance of its opposite, i.e. scientific method.

4) The reproduction of the concrete by means of thought, or dialectical knowledge as a historically specific form of the objective consciousness of the working class as revolutionary subject.

Thus far we have recognized the specific historical determination of logical representation as the necessary form of objective consciousness in the capitalist mode of production. It is the necessary form of the production of relative surplus value which, as such, deprives its subject -more concretely, the working class as a political subject- of the possibility of becoming objetively aware of its powers as historical subject. A question immediately arises: which is, then, the form of objective knowledge inherent to the working class's own historical subjectivity, with the capacity to organize the supersession of the capitalist mode of production?

This kind of knowledge does not come to a halt in the face of the appearance that the concrete existence upon which we intend to act is devoid of any objective potentiality to be actualized. If it lacked this potentiality, any action aimed at transforming the concrete existence under consideration would be utterly impotent. Consequently, our process of cognition must confront this concrete existence by means of an analysis that recognizes it precisely in its condition as an actual existence which, at the same time, embodies a potentiality to be realized. But in order to act upon this potentiality, our knowledge needs to account for its necessity. And the latter resides in the very form as an actual existence of the concrete object we are facing. In turn, this actual existence is the product of the realization of a potentiality which determined it as such actual existence. In other words, our analytical process must pierce deeper into the concrete existence that constituted the starting point in search of the necessity which is already realized in it. The point now is therefore to discover the form in which the initial concrete still existed as a pure potentiality to be actualized. Upon which, we must then account for the necessity of the newly discovered concrete existence.

Schematically put, we faced at the beginning concrete existence A, whose potentiality α could be realized by means of our action. In order to account for the necessity of this potentiality, and thus of our own action, we must account for the necessity of A as an already realized actual existence. We analyse A, and find that it is the concrete form in which concrete existence B had realized its own potentiality β. We must now explain the necessity of this newly discovered potentiality, which we do by moving to the analysis of B as an already realized existence. We thereby arrive at concrete existence C, whose potentiality χ is realized under the concrete form of B. As should be clear from this schematic presentation, the analysis does not consist, as it does according to logical representation, in the abstraction of a recurring attribute. Instead, this dialectical analysis moves through the discovery of the necessity-content that determines each concrete existence which, in turn, can only be done by facing the necessary concrete form of realization of the said content. As a consequence, this form of analysis renews on each turn the inquiry into the necessity of its object, without being able to stop until discovering it under its simplest and most general form of actual existence. The simplicity and

---

determined social being be represented as if it were organised by a 'false consciousness', and not by his/her necessary concrete form of consciousness (ibid., pp. 224-225).

generality of the latter stems from embodying no potential necessity other than that of self-transcendence or self-actualization, that is, of affirming through self-negation. This analysis thus culminates when facing matter, that is, objective existence, under its simplest and most general form.

So far the course of our process of cognition has proceeded by inquiring into the objective content's necessity, starting with the analysis of the latter's realized form of existence. Conversely, at the juncture in which the analytical process culminated, the only necessity to account for at our disposal is that of the content's equally necessary forms of realization. No sooner than this content realizes its potentiality under its necessary concrete form, the resulting concrete existence confronts us as an actual existence whose necessity we already know, but which, however, embodies a potentiality whose realisation we still need to follow by means of thought. In this way, we move forward from the simplest and most general expression of determination, reproducing by means of thought the realization of that determination under its necessary concrete forms. This *synthetic* process stands in stark contrast with that of logical representation, which revolves around the removal of simplifying assumptions. In order to clarify this point, let us briefly return to our schematic presentation.

At this juncture, we already know the necessity of C as an actual existence which embodies the potentiality χ. Thus, in order to make progress in the knowledge of our action's necessity we must follow the actualization of potentiality χ in its concrete from B, etc. Eventually, this path will lead us to confront concrete existence A again, but now as an existence whose determination we objectively know, given that we have followed the unfolding of its necessity by means of thought. Likewise, we thereby also know A's necessity in its form of existence as potentiality α, whose realization is still pending. In turn, we can therefore recognize which form of our action can act as a concrete mode of realization of potentiality α, in the transformative shape that we, as determinate subjects, consciously and willingly intend. In other words, the subject of an action organized by means of this kind of knowledge, finds that in order to govern his/her own potentiality vis-à-vis that of his/her object, he/she needs to ideally follow both the object's necessity as well as his/her own through their unfolding. Furthermore, this process cannot come to a halt until reaching the point in which each necessity is respectively revealed in its determination as a potentiality of the object whose necessary concrete form of realization is but the transformative potentiality of the subject. It is a dialectical process of cognition which takes shape by reproducing in thought the motion unfolded in reality by the development of the subject of action's own necessity with respect to that of his/her object.

The dialectical process of individual knowledge that faces its object as an already constitutive portion of social knowledge, cannot take for granted the latter's existence and represent it as the foundation of its own objectivity. Otherwise, it would cease to be a reproduction of the concrete in thought and develop the exteriority of a representation, i.e. it would become an interpretation. Its own form leads it to penetrate by itself in the real concrete it faces in order to, subsequently, ideally reproduce the latter's potientiality, as a mode in which the subject organises his/her action.

Thus, recourse to already existing dialectical knowledge only provides the subject with the possibility of approaching the concrete upon which him/her will take action, equipped with a guideline on the necessity which must be sought in the object under consideration. What was an intricate search with no guide but its own wandering about in the purely original process of cognition, turns into the possibility of directly inquiring if the already-known necessity is at stake in the proces of *re-cognition*. It is, however, just a guide. Once the process of recognition discovers in its singular concrete a different necessity from the one to which previously-existing knowledge was pointing to, or discovers one which trascends the latter, it thereafter itself becomes a purely original process of cognition. Therefore, each individual reproduction of dialectical knowledge inevitably subjects existing social knowledge to criticism, thus making it account for its continuing validity.

In fact, Marx makes our proces of recognition confront the specificity of this form of dialectical knowledge at the very onset of the development of scientific knowledge: 'I do not start out from "concepts" […] What I start out from is the simplest social form in which the labour-product is presented in contemporary society, and this is "the commodity"'.[36] Accordingly, as the starting point is a concrete and not its concept, the necesity that guides its unfolding cannot be external to such concrete. And it is Marx too who, in the following remark, makes our process of recognition account for this determination within our object, i.e. within the method of dialectical knowledge: 'Logic […] is *alienated thinking*, and therefore thinking which abstracts from nature and from real man: *abstract* thinking'.[37]

Without a concept as starting point and an abstract ideal necessity to follow, Marx places our process of recognition before the need of explaining why, due to this concrete determination, the method of scientific knowledge in question is necessarily *the opposite of the unfolding of a conceptual system*, however dialectic this may be: 'It will be necessary […] to correct the idealist manner of the presentation, which makes it seem as if it were merely a matter of conceptual determinations and of the dialectic of these concepts. Above all in the case of the phrase: product (or activity) becomes commodity; commodity, exchange-value; exchange-value, money.'[38]

Likewise, Marx confronts our process of recognition with the need of wondering why *it is not a matter of opposing a scientific unfolding of the concept to dogmatic or doctrinal conceptions*: 'Just as from the dialectic movement of the simple categories is born the group, so from the dialectic movement of the groups is born the series, and from the dialectic movement of the series is born the entire system. Apply this method to the categories of political economy and you have the logic and metaphysics of political economy [...] which makes them look as if they had newly blossomed forth in an intellect of pure reason'.[39] And, finally, he makes our process of recognition account for the dialectical method in its unity as the *'reproduction of the concrete by way of thought*',[40] *in contrast to logical representation and its conceptual systems.*

On advancing in this manner, we recognize *Capital* as the historically-unprecedented unfolding of the reproduction in thought of the necessity that determines the historical *raison d'être* of the capitalist mode of production and, as a consquence, the action of the working class as bearer of its revolutionary supersession through the development of a community of freely associated individuals. In other words, a community of individuals with the power to organise their action for objectively knowing their own determinations beyond any apparent exteriority. Marx has produced this unfolding by giving this original knowledge an objective social existence suitable for appropriation by others, i.e. by giving it the form of a published text.

After *Capital*, all reproduction in thought that moves through the determinations unfolded in it, becomes thus determined as a process of recognition from a social point of view. But it is not a matter of *interpreting* it. It is truly about confronting the real forms of capital ourselves, in order to attain our potientiality as historical subjects on reproducing such forms by means of thought. However, we can undertake the task with the enhanced power we acquire with the availability of the ideal reproduction of those real forms as already developed in *Capital*. In this sense, we have a two-fold advantage compared to Marx. First, we have the product of Marx's social labour to empower our progress towards the free organization of the process of human life. Second, we face the immediate object of our action, capital, under much more developed historical forms than those that Marx confronted in his time. Concrete forms that existed as barely emerging potentialities then, lie now before us in their full actuallity. All of which leaves its mark on our responsibility as historical subjects, whose action towards superseding the capitalist mode of production involves, as a necessary inner moment, the collective production of a consciousness capable of organising our own action with the objective power of dialectical knowledge.

If in the course of reproducing by means of thought of a concrete upon which we are taking action we confront different forms from those faced by other subjects in their own inquiry, our reproduction will cease to be a process of recognition from a social point of view to become an original process of cognition. Let us take, in this sense, the specific case of a divergence from the forms discovered by Marx himself. At this stage of our discussion, it should be clear that at stake here is not the organization of our action as organs of the process of social life by means of one or another way of *interpreting* Marx. Thus, insofar as the question actually is that of acting on the basis of an objective knowledge of our own determinations with the potientiality to transcend the appearances which characterise all interpretation, we shall not undertake an ideal *representation* of the concrete. In line with the interpretive character of such representation, the difference between one's own claim and Marx's writings, even if contradicting the latter openly, are settled by maintaining that the former is in fact 'what Marx really meant'. Subsequently, the next step is to propose a certain organization of social action founded on such interpretation. However, in all this it is never acknowledged that the proposed course of action is founded on its advocate's own ideal construction. Instead, it is presented as if it had entered the realm of theoretical representations under the aegis of the *true* Marx, i.e. as *Marxist theory* or simply *Marxism*.[41]

By contrast, in its self-recognition as the organizational instance of its subject's action, the reproduction of the concrete by means of thought cannot lay claim to the ability to speak in someone else's name , even if the concrete forms it has gone through in its development are identical to those already presented by this other individual. Needless to say, the same goes for non-identical forms. Hence, instead of speculating on the hermeneutics or philological readings of *Capital*, we might as well summarize the point by stating that 'what Marx found on his scientific development was Marx's problem; what we encounter on facing our real concrete, whether the same as Marx's or not, that is our problem'.[42]

Finally, and by way of concluding remark: Why, when we undertake this path and objectively recognize that the capitalist mode of production means exploitation and alienation of the worker as an attribute of capital, should we degrade that objective knowledge by referring to it under name types designating interpretations of reality? Is it not the case that, when we state with certainty that the Earth revolves around the Sun, or that blood circulates through arteries and vains, we do it on of the basis of objective knowledge and not because we are Copernican or Harveyist?

---

[41] Particularly notorious examples of this practice are *Ricardian Marxism's* reduction of value to its content, or the reduction of value to its form, as done by *Rubinist Marxism.* Both reductions lead to the representation of human freedom as a natural attribute thus avoiding its recognition as a historical social relation born out of the production of commodities as a necessary form of the consciousness alienated in them. And both reductions are the grounds for the inversion of the *critique of political economy* into *Marxist political economy* precisely insofar as the naturalization of an abstractly free individual is intrinsic to political economy (See Iñigo Carrera, Juan, *Conocer el capital hoy…*, op. cit., pp. 107-187).

From the negation of the materiality of abstract labor to the abstraction of the revolutionary subject's free will. The case of Michael Heinrich[*]

Juan Iñigo Carrera

Translated by Leonardo Kosloff

- *Heinrich (The New Reading of Marx)*

According to Heinrich:

> Every act of labor whose product (which can also be a service) is exchanged produces value.[1]

This statement, which may initially appear as a simplification, is the first step in Heinrich's shift towards the inversion of the substance and the form of value. According to him, it's not that labor that produces commodities possesses a socially specific attribute that determines them as values, that is, as bearers of the anti-natural ability to relate to each other in exchange. Instead, for Heinrich, it is the fact that the products of labor are exchanged that determines the latter as a producer of value. The inverted determination of value-producing labor by the fact that its products are exchanged, is then followed by the reduction of value-producing labor to an abstract labor, which is abstracted from its historically specific determination by the private form that social labor takes in the capitalist mode of production. And as is customary, Heinrich makes this abstraction of the abstract labor that produces value by invoking the name of Marx:

> Marx therefore speaks of value-producing labor as 'abstract labor.'[2]

Heinrich thus erases the fact that when labor is organized in a directly social manner, the general productive expenditure of the human body, or in other words, abstract human labor, does not produce value. This is precisely why he takes the first step in the inversion: if, at the starting point, labor owes its status as a producer of value to the fact that its products are exchanged, followed by the idea that abstract labor produces value, this erases the possibility of there being abstract labor that does not produce value. Furthermore, the apparent simplicity of Heinrich's phrase contains another step in the erasure of the materiality of abstract labor and its specific social determination as a producer of value by the private character of labor:

---

[*] Taken from *Conocer el capital hoy. Usar críticamente "El Capital"*, Vol. 1: 'La mercancía, o la conciencia libre como forma de la conciencia enajenada' (*Knowing Capital Today, Using "Capital" Critically*, Vol. 1: 'The commodity, that is, free consciousness as the form of alienated consciousness')

[1] Heinrich, Michael, *An Introduction to the Three Volumes of Karl Marx's Capital*, New York, Monthly Review Press, 2012, p. 48.

[2] Heinrich, Michael, op. cit., p. 48.

> Marx therefore describes abstract labor as the "value-forming substance" or as the "substance of value." The "substance of value" as a figure of speech has frequently been understood in a quasi-physical, "substantialist" manner: the worker has expended a specific quantity of abstract labor and this quantity exists within the individual commodity and turns the isolated article into an object of value.[3]

Not only has the analysis unfolded to discover the specificity of value-producing labor been reduced to a mere "Marx speaks of", but the discovery of socially necessary abstract labor materialized privately and independently in its product as the "substance of value" is degraded to the status of a mere rhetorical "figure of speech." In this way, Heinrich turns the substance of value into a purely ideal existence, a pure concept:

> Abstract labor is not visible, only a particular concrete labor is visible, just as the concept of 'tree' isn't visible...[4]

Heinrich denies the visibility of a materiality that is immediately visible: the materiality of the fact that when a human being works, they are productively expending their body, regardless of the specific form in which they do so, and materializing that expenditure in their product, whatever it may be. Moreover, when it comes to simple commodity producers, each of them has full control over this expenditure of their body, performing it privately and independently. Thus, his conception of abstract labor, which started by inverting the determination of its historical specificity as a producer of value, closes its inverted circle, presenting the materiality of abstract labor as devoid of its historical specificity due to the private form of social labor, as an abstract mental construct, impotent to account for the historically specific determination of value:

> The reduction of various types of labor to labor in a physiological sense, however, is a purely mental abstraction, to which any kind of labor can be subjected, regardless of whether it produces a commodity. Furthermore, this formulation suggests that abstract labor has a completely non-social, natural foundation, and has therefore accordingly provoked "naturalistic" interpretations of abstract labor. [...] Abstract labor, on the other hand, cannot be "expended" at all.[5]

---

[3] Heinrich, Michael, op. cit., p. 49.

[4] Heinrich, Michael, op. cit., p. 49.

[5] Heinrich, Michael, op. cit., p. 50.

In summary, where Marx literally expounds his discovery regarding the materiality of abstract labor as the productive physiological expenditure of any human body under any concrete form, common to all forms of society,[6] but that only when performed privately and independently, its materialization in the product represents the latter's attribute to socially relate its producers,[7] Heinrich believes he sees "naturalistic interpretations" of a "concept," resulting from a "purely mental abstraction." The entire secret of the apparent analysis through which Heinrich arrives at this erasure of the substance of value was already present in the initial inversion of that analysis, where labor appeared to owe its status as a producer of value to the fact that its product was exchanged.

Once he has emptied value of its substance, Heinrich aims to present this same substance as emerging from the form of value, that is, from exchange value.

> Abstract labor is a *relation of social validation* (*Geltungsverhaltnis*) that is constituted in exchange. In exchange, the concrete acts of expended labor *count* as a particular quantum of value-constituting abstract labor, or are *valid* as a specific quantum of abstract labor, and therefore as an element of the total labor of society.[8]

In light of this conception of abstract labor, the immediate question arises: What is the norm that governs this "relation of social validation", that is, what is the necessity which is realized by taking form in it? In other words, why should the product of a certain concrete labor normally be validated as equivalent to x amount of "abstract labor" and not some other amount? Or, what determines that the product of x hours of concrete labor is normally validated as equivalent to the product of y hours of another concrete labor, insofar as they are "abstract labor"? And, in a more general sense, on what qualitative basis is said "social validation" determined quantitatively? Because, in the real world, exchange still takes the form of a quantitative relationship, the existence and commensurability of which presupposes the existence of a common quality in both poles of the relationship.[9] Let's examine it:

---

[6] In Marx's original terms:

> The mystical character of the commodity does not therefore arise from its use-value. Just as little does it proceed from the nature of the determinants of value. For in the first place, however varied the useful kinds of labour, or productive activities, it is a physiological fact that they are functions of the human organism, and that each such function, whatever may be its nature or its form, is essentially the expenditure of human brain, nerves, muscles and sense organs. (Marx, Karl, *Capital*, *Volme 1*, London: Penguin Books, 1982, p. 164)

[7] Again, in Marx's terms:

> Something which is only valid for this particular form of production, the production of commodities, namely the fact that the specific social character of private labours carried on independently of each other consists in their equality as human labour, and, in the product, assumes the form of the existence of value, ... (Marx, Karl, op. cit., p. 167)

[8] Heinrich, Michael, op. cit., pp. 50-51.

> Value-objectivity (*Wertgegenstandlichkeit*) is not possessed by commodities as objectifications of concrete labor, but rather as objectifications of abstract labor. However, if as we just outlined, abstract labor is a relation of social validation existing only in exchange (where privately expended labor counts as value-constituting, abstract labor) then value also first exists in exchange. What's more, value is not at all a property that an individual thing possesses in and of itself. The substance of value, that constitutes the foundation of this objectivity, is not inherent to individual commodities, but is bestowed *mutually* in the act of exchange.[10]

Heinrich's response skips from the sheer material heterogeneity of concrete labor to the private form in which social labor is organized. This form lacks inherent materiality, as is evident. It leads to an "abstract labor" that, thanks to the leap taken along the way, has shed its materiality to become an abstractly conceptual existence. This existence is entirely devoid of a substance that can be manifested in exchange, since it now turns out that exchange itself generates it.

Private labor is a way of organizing social labor, that is, assigning the materiality of the total labor capacity of society to the various specific and useful forms of labor to be physically carried out by each productive member of society. Without a doubt, this historically specific form of making such an allocation operates by determining the material forms through which social labor is executed. It does so by giving each producer full control over their individual labor and depriving them of any control over its social character. However, this fact does not change in the slightest that the materiality of labor is irreducible to the social form of its organization. Therefore, invoking "private labor" does not resolve the question that, in the equality relationship between quantities of qualitatively distinct use-values, there must be an underlying common quality of the labor privately materialized in them, and that this quality is alien to the heterogeneity of concrete labor.

It is then that Heinrich attempts to evade the issue by turning it upside down: it's not that the exchange reveals that both poles of the relationship possess the same property in equal quantity, but that the realization of the exchange relationship establishes a quantitative proportion abstracted from all qualitative content, resulting in the existence of a common quality. In other words, according to Heinrich, it's not that the exchange relationship reveals that commodities have an attribute that has allowed them to enter it, but that commodities enter exchange devoid of attributes and emerge from it with the attribute of being "values," whereas the labor that produced them emerges with the attribute of being "abstract."

---

[9] It pertains a property inherent to the thing and the necessity that this property carries within itself, by its very determination, to manifest itself in a relative form:

> However, the properties of a thing do not arise from its relations to other things, they are, on the contrary, merely activated by such relations. (Marx, Karl, op. cit., p. 149)

[10] Heinrich, Michael, op. cit., pp. 52-53.

On this basis, Heinrich takes one step further in denying abstract socially necessary labor which is privately and independently embodied in its product as the substance that constitutes the qualitative foundation that is objectified in the relationship of equality that takes form in exchange. He inverts the former as if it were emerging from the very existence of that exchange, so that the determination of value is posited on its necessary form of exchange value:

> Only labor-time expended under the average existing conditions of production as well as for the satisfaction of monetary social demand constitutes value.[11]

Even the mere reference to "labor time expended under average production conditions" corresponding to a certain type of commodity reveals the erasure of the material quality of labor that Heinrich has had to resort to in order to reduce it to the abstraction of its pure social quality as "private labor." The reference to different production techniques converging to form an average quantity of labor spent implies the coexistence of different forms of concrete labor applied to produce the same type of use value. Therefore, the determination of the average amount in question requires the existence of a common quality, not just among different branches but within each of them. The expenditure of human labor power in general, that is, the materiality of socially necessary abstract labor performed privately, sneaks into Heinrich's determination of the exchangeability of commodities, no matter how much he tries to expel it to the realm of concepts.

However, now, even the determination of the "socially necessary" character itself suffers the consequences of denying the determination of the substance of value by the materiality of privately and independently performed abstract labor. It is no longer a matter of how the private allocation of the capacity to perform social labor gives each producer full control over their individual concrete labor at the expense of having no control over the determination of their product as socially useful or useless. As a result, the product of socially necessary labor performed privately can only acquire that condition at the very moment when labor is materializing in it, that is, at the very moment of its production. But the fact of possessing such an attribute, that is, being a commodity, can only manifest itself when that product proves to be a bearer of it by entering into an exchange relationship with another commodity in quantities of whose body it expresses its value, meaning the latter functions as its equivalent. Therefore, the socially necessary character of a certain amount of privately materialized abstract labor will always manifest itself as such in circulation, being confronted as a counterpart with a social need capable of being represented through that equivalent. Correspondingly, the socially useless character of privately materialized abstract labor will manifest its condition as such when attempting to enter into an exchange relationship and being unable to do so because it lacks the necessary attribute. It is the fact that social labor is performed privately which determines that the unity between production and social consumption can only be established in this indirect manner, after production has been completed.

---

[11] Heinrich, Michael, op. cit., p. 50.

Consequently, this indirect unity takes the form of the relationship between the supply and demand for these commodities in circulation. Once again, it is the substance of value that determines the necessity of its form.[12] Nevertheless, as Heinrich denies the substance of value in order to reduce it to a "social validation" that occurs in circulation, the socially necessary character of value-producing abstract labor is inverted under the form of "*as well as* for the satisfaction of monetary social demand," which determines the extent of that validation. And once again, the form appears inverted as determining the necessity of the substance. From this inverted perspective, it would be necessary to first understand what money is and what demand is to explain what value is.

From the same inversion, Heinrich subsequently argues that in determining the value of a commodity, the relationship between its supply and demand plays a role. This implies that under any circumstances, commodities are always sold at their value. It also implies, therefore, the impossibility of the existence of a substance of value that determines the exchangeability of a commodity, except for the magnitude of its "social validation" by the very equality established in exchange:

> To what extent the privately expended labor was actually necessary to satisfy demand depends on the one hand upon the amount of this demand and on the other hand upon the volume of production of other producers—both of which first become apparent in exchange.[13]

The analysis of this determination requires going beyond the question of the substance of value and its necessary form as exchange value, to advance in the unfolding of its concrete movement in circulation. This implies that we must proceed by reproducing on our own the development that Marx presents in the third chapter of 'Capital' regarding the function of money as a means of circulation. Having done this, our exposition is confined here to the specific determination in question.

Heinrich considers that to back up his assertion, it is sufficient to present a quote from Marx. Let's take this same quote as the starting point for our analysis. Therefore, we transcribe it with greater extension than the portion quoted by Heinrich:

> We suppose him to have spent on his product only the average socially necessary quantity of labour-time. The price of the commodity, therefore, is merely the money-name of the quantity of social labour objectified in it. […] Let us suppose, finally, that every piece

---

[12] 'The exchange or sale of commodities at their value is the rational, natural law of the equilibrium between them ; this is the basis on which divergences have to be explained, and not the converse, i.e. the law of equilibrium should not be derived from contemplating the divergences. … The real inner laws of capitalist production clearly cannot be explained in terms of the interaction of demand and supply […] since these laws are realized in their pure form only when demand and supply cease to operate, i.e. when they coincide.' (Marx, Karl, *Capital*, *Volume 3*, London: Penguin Books, pp. 289 and 291)

[13] Heinrich, Michael, op. cit., pp. 51-52.

> of linen on the market contains nothing but socially necessary labuor time. In spite of this, all these pieces taken as a whole may contain superfluously expended labour-time. If the market cannot stomach the whole quantity at the normal price […], this proves that too great a portion of the total social labour-time has been expended in the form of weaving. The effect is the same as if each individual weaver had expended more labour-time on his particular product than was socially necessary. As the German proverb has it: caught together, hung together. All the linen on the market counts as one single article of commerce, and each piece of linen is only an aliquot part of it. And in fact the value of each single yard is also ·nothing but the materialization of the same socially determined quantity of homogeneous human labour. … The division of labour converts the product of labour into a commodity, and thereby makes necessary its conversion into money. At the same time, it makes it a matter of chance whether this transubstantiation succeeds or not. Here, however, we have to look at the phenomenon in its pure shape, and must therefore assume it has proceeded normally. In any case, if the process is to take place at all, i.e. if the commodity is not impossible to sell, a change of form must always occur, although there may be an abnormal loss or accretion of substance - that is, of the magnitude of value.[14]

The normality that governs the indirect unity between the social production and consumption of a commodity corresponds to the point at which its producers, collectively, have privately applied a total amount of abstract labor that puts them in a position to dispose of the product of the same amount of abstract labor materialized privately by other producers under the concrete forms from which the commodities that satisfy the needs of the former result. Consequently, the key regarding the question of whether or not the imbalance between supply and demand intervenes in the determination of the value of commodities lies in discovering if, when the former exceeds the latter, the substance of value which is abnormally suppressed in circulation has vanished without a trace. In the inverse case, the key lies in discovering the source of the substance of value which is abnormally added in circulation.

Let's assume that the abstract socially necessary labor required to produce one unit of commodity A is 10 hours, a value substance expressed as $10, and that the solvent demand - that is, the social need capable of being represented by value - corresponding to this value is 100 units. However, let's assume that the producers of A have produced 110 units, meaning that instead of applying the 1000 hours of socially necessary abstract labor, they have applied 1100 hours. Let's assume that for the solvent demand to expand and reach this quantity, each unit must be sold for $9. Finally, let's assume that all buyers of commodity A have sold their own commodities for their value, so they have received $1 for the product of each hour of socially necessary abstract labor they have performed.

When they meet their buyers in circulation, the sellers of A deliver the product of 1100 hours of socially necessary labor, but only receive $990. They have contributed the product of those 1100 hours of socially necessary abstract labor to social consumption but can only withdraw for themselves the product of 990 hours of the same labor. Indeed, from their point of view, 110 hours of socially necessary abstract labor, or value substance, have vanished.

---

[14] Marx, Karl, *Capital, Volume 1*, op. cit., pp. 201-203.

But let's look at the same situation from the buyers' point of view. They have contributed the product of 990 hours of socially necessary abstract labor to social consumption, but have taken from the market the product of 1100 hours of the same labor. In the indirect unity between production and social consumption, the entire product of the 2090 hours of privately performed socially necessary abstract labor has passed into the sphere of social consumption. However, precisely because of the private manner in which this labor has materialized in its product under the respective concrete forms, some producers have applied 1100 hours of their labor to produce for social consumption and received the product of 990 hours of socially necessary labor, while others have contributed to social consumption the product of 990 hours of socially necessary labor and received that of 1100 hours. Far from simply vanishing in circulation, the portion of the value substance in question has been appropriated by those who bought the commodities in which it was materialized by paying below their value.

Let's consider the inverse case. Suppose the producers of commodity A have only produced 90 units and, therefore, applied 900 hours of socially necessary abstract labor. Suppose that for the normal solvent demand to contract to this quantity, each unit must be sold for $11. Let's continue assuming that all buyers of A have sold their own commodities for their value. Now, the sellers of A deliver the product of 900 hours of socially necessary labor, but receive $990. They have contributed to social consumption the product of 900 hours of socially necessary abstract labor but withdraw for their own consumption the product of 990 hours of equal labor. From their point of view, the exchange has added 90 hours of socially necessary abstract labor, or in other words, value substance to their product, without them having to lift a finger beyond what is normal for them. But let's place ourselves on the other side of the counter. The buyers of A have contributed the product of 990 hours of socially necessary abstract labor to social consumption, but have only taken from the market the product of 900 hours of equal labor. In the indirect unity between production and social consumption, all the product of the 1890 hours of socially necessary abstract labor carried out privately has been absorbed by social consumption. But while some producers have brought the product of 900 hours of that labor to this consumption and disposed of the product of 990 hours for themselves, others have found themselves in the opposite situation. Far from simply adding new value substance to commodity A in circulation, the portion in question has been originally produced by the socially necessary abstract labor of those who then lost it in favor of the producers of A, by buying it and paying above its value.

> But although price, being the exponent of the magnitude of a commodity's value, is the exponent of its exchange ratio with money, it does not follow that the exponent of this exchange-ratio is necessarily the exponent of the magnitude of the commodity's value.[15]

---

[15] Marx, Karl, *Capital, Volume 1*, op. cit., p. 196.

No matter how much the prices at which commodities are exchanged may differ from their values, in circulation, no more or less value substance changes hands than what enters it. As the substance of value, abstract labor is not a "validation relationship" that arises in exchange, nor does the relationship between supply and demand enter into its determination:

> It becomes plain that it is not the exchange of commodities which regulates the magnitude of their values, but rather the reverse, the magnitude of the value of commodities which regulates the proportion in which they exchange.[16]

The absurdity of pretending that the relationship between supply and demand intervenes in the determination of value is evident, even by simply considering that if it did, commodities would always appear to be sold and bought at their value. In which case, there would never be any deviation from normalcy because it would be a normalcy lacking determination, except for being simply fluctuating at the rhythm of said relationship. Even the average of these "values" would appear to have no necessity other than chance, since if value were that abstract "validation relationship" lacking all substance preexisting the exchange itself, supply and demand would always emerge equal from that same exchange. Thus, producers of commodities would have no way of recognizing whether their action as private individual organs of the process of social metabolism should be modified in one direction or another around a norm.

Curiously, the "new reading of Marx" converges towards the most vulgar neoclassical economics in attributing to the interplay between supply and demand the capacity to determine value. And, like it, it can only be sustained upon its own contradictions. As we have already seen, Heinrich has explicitly told us that:

> However, if as we just outlined, abstract labor is a relation of social validation existing only in exchange (where privately expended labor counts as value-constituting, abstract labor) then value also first exists in exchange.[17]

But now he reprimands us for falling into the 'nonsense' of believing him, because it turns out that the very value and, by logical consequence, the 'abstract labor that constitutes value,' already exist in production, an activity that obviously precedes the circulation where the exchange occurs:

> However, even the question as to whether value and the magnitude of value are determined in the sphere of production or in the sphere of circulation (the sphere of buying and selling) is the result of a fatal reduction. Value isn't just "there" after being "produced" someplace. … But value isn't a thing like the bread roll, but rather a social relationship that *appears as a tangible characteristic* of a thing. The social relationship

---

[16] Marx, Karl, *Capital, Volume 1*, op. cit., p. 156.

[17] Heinrich, Michael, op. cit., pp. 52-53.

> that is expressed in value and the magnitude of value is constituted in production *and* circulation, so that the “either/or” question is senseless.[18]

Far from being a materialized social relationship, which as such takes the form of a spectral materiality, what Heinrich presents to us is a kind of production process capable of going back to the future, since it is governed by a value that does not yet exist. Thus, value can go from being "a social relation that appears as a tangible characteristic of a thing" to being the expression of a social relation, that is, something which is not the social relation itself in its entirety, while this social relation conveniently remains with its specificity wholly undefined, and even unnamed. Such ambiguity allows it to be everywhere, even in those places where this same conception asserts that it cannot be.

We have already seen Rubin's reaction to Marx's exposition in Capital regarding abstract labor as the generic physiological expenditure of human body applied productively, which only when materialized privately and independently in its product under a socially useful concrete form and under normal conditions, is represented as the historically specific purely social attribute of said product, as the value of commodities. Where Marx discovers this simplest and most fundamental determination of the general social relation in the capitalist mode of production, Rubin sees an incoherent writer who literally wrote sentences incompatible with his own theory of value. And even someone who intellectually regressed from his own previous work, the Contribution to the Critique of Political Economy, "where Marx developed his theory more completely." Heinrich not only shares Rubin's first perspective, but also shows himself determined to fuel the second. Thus, Heinrich sees a Marx whose knowledge of value and its form has reached "emphatic clarity" when writing a draft in preparation for the second edition of Capital, only to fall back and end up falling into the abominable assertion, typical of "naturalistic interpretations," of the physiological character of abstract labor in the published text. As he puts it:

> The substance of value, that constitutes the foundation of this objectivity, is not inherent to individual commodities, but is bestowed *mutually* in the act of exchange. The most emphatic statement on this by Marx can be found in his revised manuscript for the first edition. There he states that when a coat is exchanged for linen, then both are “reduced to an objectification of human labor per se.” However, it should not be forgotten that “*none of both is in and of itself value-objectivity* [Wertgegenstandlichkeit], they are this only insofar as that this objectivity is commonly held by them. Outside of their relationship with each other—the relationship in which they are equalized—neither coat nor linen possess value-objectivity or objectivity as congelations of human labor per se.” (MEGA, 2.6:30).[19]

---

[18] Heinrich, Michael, op. cit., p. 54.

[19] Heinrich, Michael, op. cit., p. 53.

To begin with, the existence of a substance and its expression or objectification are not synonymous. Everyone knows that thought is the substance that is socially objectified in words when one speaks, even though there may be those who seem to speak without thinking. That is, thought exists per se, but due to its qualitative determination, it cannot manifest itself on its own, it needs to be expressed as the substance that takes form in words.

But Heinrich goes beyond the identification between substance and objectification. What he does is distort the flow of Marx's text. He attributes to Marx the assertion that it is through exchange, that the coat and the linen are "reduced to an objectification of human labor per se". But Marx explicitly reaches that point in his draft through the exposition of the process of *analysis* of the immediate manifestation of the exchange relation. And it is through this process of analysis that he discovers abstract labor as the substance of value. His discovery of the latter, therefore, runs in the opposite direction to the process of unfolding its necessary form as exchange value, that is, opposite to the way Heinrich seeks to present it:

> Commodities acquire *value expression* (value form) only in *relation* to one - other. […] Where does this come from? How does this peculiarity, common to all forms of value of the commodity, arise from the concept of value? We originally found the *concept of value* of commodities as follows: We took an exchange relation like *1 coat = 20 yards of linen*. We said: the coat and linen express something in *common* here [...] This same something is not their use-values or material usefulness […] In their equation it is abstracted. It is, therefore, their character as *products of labor*. […] As products of labor, they are the same insofar as they are products of the same labor, i.e. the coat, like the linen, is regarded *as a mere objectification of human labor per se*. This is their *value*. Thus, the coat and linen as values, each one for itself, were reduced to the *objectification of human labor per se*.[20]

From the "none of both..." onwards, what follows in the quote presented by Heinrich, Marx clearly refers to the objectification or necessary expression of value in the form of exchange value, not to the determination of its substance as the objectification of abstract human labor. It is worth noting that because socially necessary abstract labor, which constitutes the substance of value of a commodity, is performed privately and independently, no commodity can present its own body as the objectification of its own value. The value of a commodity can only manifest itself by being objectified in quantities of the use-value of another kind of commodity, thus taking its specific form of exchange value.

But Heinrich adds a second quote from the same draft that he considers decisive:

---

[20] Marx, Karl, «Ergänzungen und Veränderungen zum ersten Band des "Kapitals"», in *Karl Marx Friedrich Engels Gesamtausgabe (MEGA)*, Volume 6, Division 2, Berlin, Dietz Verlag, 1987, pp. 29-30, (JIC translation).

> As a consequence, “a product of labor, considered in isolation, is not value, nor is it a commodity. It only becomes value in its unity with another product of labor.” (MEGA, 2.6:31).[21]

However, the apparent forcefulness of the quote has no more support than the selective excerpting of Marx's text (Heinrich’s excerpting is underlined):

> *The value form of the commodity as given in the value relation of different commodities.* 1) The production of the materializations of labor as values reduces them to expressions of the *same unity*, (to expressions that which they have in common, expressions of that what is the same in them) to *human labor per se* as their *common substance*. This includes: *relation* to human labor as a unity, relation of the commodities to each other, as expressions of the *same* unit. *Or the relation of the products of labor to each other as expressions of this same unity is their value-being*. And it is only through this relationship that mere *products of labor* become useful objects – *commodities*. Therefore, a product of labor, considered in isolation, is not value, nor is it a commodity. It only becomes *value* in its *unity* with another product of labor, or in the proportion within which the different products of labor, as crystals of the same unit, human labor, are equated with each other. It follows, therefore, because the *value* of commodities is nothing but their *relation to labor* as their common substance, or their *relation to each other* as an expression of this common substance, that this value of a commodity can also only appear in the *value relation* in which it relates to other commodities, or only in the *value relation of different commodities*. Hence value expression can only be found, or commodities can only obtain value form, in their *relation to other commodities*. This shows us how the value form arises from the nature of value itself. If I say that this product of labor is value because human labor is expended in it, then this is merely the subsumption of the product of labor under the concept of value. It's an abstract expression that encompasses more than it says. For this product of labor is only reduced to this concept of value, in order to reduce it as a *thing of the same substance* as all other products of labor. The relation to other products of labor is therefore implied. […] The expression, although it says nothing of this relationship, includes it.[22]

At first glance, it may seem that Marx is simply unfolding the formal necessity of the unity between the substance of value and its objectification in exchange. The substance arises in production, where the products of labor acquire the common quality that enables their relationship as materializations of human labor per se. As a common quality of the products of labor, this substance cannot be objectified as a relation between the body of each product and the labor that produced it per se. It can only be objectified through the relationship between the bodies of commodities containing equal quantities of it, that is, as exchange value. But what Marx is truly unfolding is the real necessity of the unity between the substance of value and its form as exchange value. It is only that here, Marx does not directly make explicit the specificity of commodity-producing social labor. That is, he does not directly refer to it as socially useful labor organized privately and independently. But he implicitly introduces this specificity of commodity-producing labor by transitioning from the abstract attribute, which up to this point is only formally common to commodities, to the concrete exercise of this attribute in its determination as the real capacity of commodities to enter into the relation of exchange. This capacity is lacking in products of labor organized in a socially direct manner, despite also being materializations of human labor per se. Therefore, the term "value" is not abstractly reduced to the expression of "materialized abstract labor." It expresses the specific determination of privately materialized abstract labor that needs to manifest its socially useful condition through the entry of these materializations into relations of equality with their equivalents. Hence, the term "value" includes the necessity of the exchange relation, the necessity to express itself in the exchange relation.

---

[21] Heinrich, Michael, op. cit., p. 53.

[22] Marx, Karl, «Ergänzungen und Veränderungen zum ersten Band des "Kapitals"», op. cit., pp. 29-30, (JIC translation).

It is not in vain that Marx emphasizes that his exposition "shows how the form of value arises from the very nature of value." This is the complete opposite of the inverted appearance that Heinrich attempts to present, with the intention of making it seem as if Marx is saying that the substance of value arises from its form. The "most emphatic statement made by Marx", to which Heinrich appeals in support of his inverted construction, actually demolishes the latter into pieces as soon as the adulteration and selective editing upon which it seeks to rely are exposed.

As is characteristic of a conception in which the form determines the substance of the content, or what is essentially the same, where there is no content other than the form, Heinrich begins by denying the development of human generic essence — defined by himself as 'what separates [real humans] from animals, namely that they developed their potential and ability through labor'—[23] and alienation, as manifest objects of *Capital* .[24] Consequently, he cannot acknowledge that the historically specific form taken by the development of this human generic being in the capitalist mode of production is synthesized in the fact that its subjects confront their own social being as if they lacked it, as individuals mutually free from personal dependence who carry out their social labor privately. Therefore, they confront the development of their generic being as if it were the realization of a power alien to them, as the realization of a power that naturally belongs to the product of their own social labor. Consequently, Heinrich cannot recognize the historically specific determination of the consciousness and will of subjects as free subjects, by virtue of being alienated in the commodity; that is, it is a consciousness and will alienated due to its content, which necessarily takes shape in its opposite, in personal freedom. And he cannot recognize that the fetishism of the commodity is the simplest and most general form of this alienated consciousness. Thus, he also cannot recognize that the necessity to overcome this fetishism can only arise from the fact that the alienated development of the material productive forces of social labor needs to take shape in a consciousness that advances in its freedom by knowing itself to be objectively alienated.

---

[23] Heinrich, Michael, op. cit., p. 21.

[24] Heinrich, Michael, op. cit., p. 22.

It is thus that Heinrich ultimately reveals where his inversion of the determinations of value lead. From his inverted standpoint, value is not the simplest content of the general social relation that governs the development of a historically specific material form of the productive forces of human labor. Nor is the determination of individuals as personifications of value the concrete form in which they govern their conscious and voluntary action as individual organs of the process of social metabolism.[25] According to Heinrich, it is the reverse; the existence of value is explained by human behavior. Consequently, the necessity to overcome value is inverted into the abstract possibility of considering how to change that behavior.

> the rule of value over humans is not a natural law of society, but the result of a very specific behavior by humans, and this behavior can—at least in principle—be changed. A society without commodities and money is conceivable.[26]

And, in turn, fetishism dissolves into an abstract "structural background" that operates externally by affecting the consciousness and will of individuals, and which they can "penetrate" by opposing it with the exercise of a no less abstractly free consciousness and will:

> However, this fetishism is also not a completely closed universal context of deception from which there is no escape. Rather, it constitutes a structural background that is always present, but affects different individuals with varying strength and can be penetrated on the basis of experience and reflection.[27]

As always, behind the conception that value has no content other than its form lies the conception of human consciousness and will as inherently abstractly free by nature.

---

[25] As a whole, this is the opposite of:

*The capitalist mode of production thus exhausts its historical reason for being, namely, the development of the material productive forces of society through the transformation of the productive powers of individual free labor into powers of directly social labor consciously organized by the collective worker that carries it out, in the form of the alienation of the powers of this labor as social powers of its material product. (*Iñigo Carrera, Juan*, El capital: razón histórica, sujeto revolucionario y conciencia,* p. 39*).*

The point is to change it

'The philosophers have done nothing but to *interpret* the world in various ways; the point is to *change* it.' (Marx, Karl, XI Thesis on Feuerbach)

Marxists unanimously assume that the problem with philosophers is not that they interpret the world, but that they do not take action once they have achieved this interpretation. Moreover, Marxism has always postulated that the point is to scientifically interpret the world to face, on the basis of that interpretation, its conscious transformation. Still, is it the point? Should *interpretation* be taken as the natural form of scientific knowledge? What change are we talking about?

Free consciousness as the form of alienated consciousness[1]

The capitalist mode of organizing social production, and therefore of organizing the process of social metabolism, starts from the dissolution of the relations of personal dependency. It is about a society of free individuals, within which social labor is performed in a private way. This means that the free consciousness in charge of organizing each unit of social labor lacks the capacity to control its own social powers. These powers face that consciousness inverted as the social powers imposed on it by its product -capital- which embodies the capacity to automatically give way to the general organization of social labor bearing its self-multiplication as immediate aim. Therefore, free consciousness is determined as the necessary personification of that alien social power, that belongs to its product and to which it is submitted. That is to say, within the capitalist mode of production, free consciousness is the form of the consciousness alienated in capital.

Through the production of relative surplus value, the process of capital accumulation, i.e. the progressive socialization of private labor, is the mode of organizing social life within which social labor is constantly driven to develop the capacity to consciously control its own organization while, at the same time, it pursues as its immediate aim the multiplication of the capacity to automatically organize social life beyond the consciousness of its producers.

The absolute limit to the capitalist development of the productive forces of society lies in this negation of the complete domination of the very powers of social labor. Therefore, the ultimate capitalist barrier to the development of productive forces lies in the mutilation imposed on free consciousness by its determination as the form of existence of alienated consciousness. The overcoming of this barrier necessarily entails the annihilation of private labor as the way of organizing social labor, thus giving birth to the general conscious organization of the latter. In other words, to change the world means to transform human freedom from consisting in not being subject to the personal domination by another at the expense of submitting to domination by the social powers that belong to the product of one's own labor, to consist in not submitting to the personal domination of another, because one holds complete objective sway over one's individual labor as an organ of social labor.

The consciousness of the working class as the negation of the negation of free consciousness

The need inherent within the capitalist mode of production to develop itself towards its own overcoming into the general conscious organization of social production immediately presents us with the process of the development of consciousness. A consciousness able to organize the totality of the process of social production must have attained the power inherent in the fullness of objective knowledge, that is, it needs to be a completely free consciousness. Nevertheless, it can not reach this condition as an offspring of the previous overcoming of the capitalist mode of production. On the contrary, this overcoming is the offspring of the complete development of free consciousness. Therefore, complete free consciousness must necessarily be the most genuine product of the capitalist mode of production itself. More concretely yet, it must needs be the product of the social subject that the capitalist mode of production objectively determines as the bearer of its own overcoming, resulting from the same process in which the subject undertakes this overcoming. In a nutshell, the consciousness in question can only be developed as the product of the political action of the working class in the process of overcoming the capitalist mode of production. This action takes, as its necessary concrete form, the advance in the socialization of private labor by means of the centralization of capital as an alienated social property, which is to say, as property of the state. The consciousness of the working class able to overcome the capitalist mode of production can only be developed as a concrete necessary moment of the aforementioned process of capital centralization.

Yet, the consciousness of the working class is determined as an attribute of capital and, therefore, as a form of alienated consciousness. Above all, the free consciousness of the working class is the necessary concrete form of its alienated consciousness. Hence, it is the negation of free consciousness under the appearance of being a free consciousness. Therefore, the consciousness that bears the overcoming of the capitalist mode of production cannot be developed as the abstract affirmation of the free consciousness of the working class. It can only be developed as the free consciousness of the working class that determines itself as an alienated consciousness advancing in the denial of its own alienation. That is, as a consciousness whose freedom resides in determining itself as the negation of the negation of free consciousness.

The science of capital as a pure form of the production of relative surplus value, i.e., the theoretical representation

Capital's needs concerning scientific cognition face a contradiction. To increase relative surplus value by means of the system of machinery, capital is compelled to submit all production and consumption to science. Nevertheless, insofar as scientific cognition is simply a concrete form of the production of surplus value, science must reproduce the alienation of human consciousness in capital. At the same time it has to be an objective consciousness, it needs to be a consciousness that looks upon itself in a non-objective way by accepting the appearance of being an abstractly free consciousness. For this reason, it is about a science that needs to appear as if the foundations of its objectivity were rooted outside itself This foundation must appear to arise from a pure abstractly free subjectivity, as if it were based on philosophy[2], and more specifically, on a philosophy based on the appearance of free individuality inherent in the circulation of commodities.[3]

Scientific theory, namely logical representation, is this contradiction resolved. Scientific theory represents real concatenations by taking the forms where the necessity has been already realized needs have already been fulfilled -which is to say, the concrete forms- as if they were not, at the same time, forms that carry within themselves a necessity to be realized -which is to say, abstract forms. It thus defines real forms as unable to move by themselves. From this point of view, they can only be linked by an external relationship. It is here that logic comes into play.

Placed as incapable of moving by themselves, real forms are represented as forms that affirm themselves through the appearance of being abstract immediate affirmations. Consequently, consciousness could be affirmed as a free one or it could be affirmed as an alienated one. However, it is logically impossible for alienated consciousness to affirm itself through its own negation under the concrete form of free consciousness.

In fact, the appearance of being an immediate abstract affirmation corresponds to the actual quantitative determination considered in itself. Scientific theory subscribes to the logic that is genuinely necessary for mathematical cognition and represents it as the objective necessity that relates qualitatively the abstract immediate affirmations to which all real forms have been previously reduced. Mathematical logic is thus represented as formal logic. Based on this premise, scientific theory represents the real abstract determinations by the relationships of measure between their concrete forms. This representation allows the subject to govern actions upon real forms consciously: although the real necessity at stake is not truly known, it is nevertheless possible to act upon the magnitude of the real forms, thus transforming their quantity until this corresponds to that of a qualitatively different form. Its quality itself has thus been transformed.[4]

In turn, materialist dialectical logic takes the same abstract immediate affirmation as the simplest form of real existence.[5] Its only difference is that it represents each of these affirmations as being necessarily united with another one of the same kind which appears as opposed to the former. Thus, the consciousness of the workers is represented as the unity of their free consciousness, on the one hand, and of their alienated consciousness on the other, within the constant struggle between them. Nevertheless, these poles are clearly mutually exclusive. The fact that their free consciousness is the concrete form of their alienated consciousness remains logically inadmissible.

Scientific method as ideology

Scientific theory revolutionizes once and again human control on natural forces, based on transforming quantitative differences into qualitative differences with objective knowledge. Its development seems to have no limit other than the conscious control over all the processes that concern human life. Therefore, scientific theory would appear to be the necessary form taken by the conscious organization of the human process of social metabolism. Yet, scientific theory itself has already discovered that this is like trying to walk through quicksand.

As its initial premise is to represent real concrete forms as abstract immediate affirmations, the real necessity that determines them can only go into logical representation by being reduced to the greater or lesser degree that the repetition of the existence of the real concrete form in question could present.[6] Therefore, however the hypothetically postulated determination has been verified by comparing the foreseen results with the real ones in all the cases of similar appearance taken into consideration, this fact does not allow one to be logically certain about the unavoidable extension of the regularity to the singular case now faced, whose realization still remains pending. Therefore, theories cannot be verified previously to the action based on them. Scientific theory seeks for the solution to this impasse by turning the problem upside down: although theories cannot be verified, at least their potential falsity can be proved. Nevertheless, even the certainty about the falsity of a theory dos not solve the problem of having acquired effective knowledge on the actual determination.

Hence, scientific theory itself arrives at a logically unavoidable conclusion: given the external nature of logical representation with respect to the real needs that we aim to appropriate in thought, it is impossible to be certain about an objective knowledge before acting.[7]

The theoretical stream that directly flows from modern Positivism accepts these limitations to the scope of scientific theory -that arise from the externality of the logical necessity with respect to the real necessity that is represented- beyond any doubt. It starts with Popper's self-complacent whining about 'rationally criticizing' what cannot be 'rationally justified nor proved' to have any real content,[8] goes on with Feyerabend's degraded 'everything goes,'[9] and ends up with Rorty's open contentment with his 'objective truth' not for its correspondence with reality but because 'the widest possible intersubjective agreement' has been achieved.[10] Thus, objective scientific truth becomes any assertion that the community of scientists solidarily declares to be such. Why this privilege? Because, it is said, inasmuch as scientists pursue no interest other than knowledge itself, they are the most pure expression of free human subjectivity. Of course, free consciousness is not an abstract natural attribute but the historic specific social relation in which the consciousness alienated as an attribute of capital takes shape.

What alternatives offers us the Marxist theoretical stream, that is to say, the one whose critical position is grounded in taking Marx's texts as the model for logical representation? To begin with, we find the critical scientific theory that counts on overcoming the impotence of theory to reach the certainty concerning its truth thanks to the presumed superior self-consistency of its dialectical logic: while formal logic can only represent the results of determination in general, dialectical logic represents this determination in itself. How does

Marxist theory know this? Because it considers the form in which determination manifests itself once and again as the unity of two opposite elements[11]. Or because it thus acquires a greater range in its 'explanatory power,' in its ability to demonstrate the necessity of the observed phenomena[12]. Nevertheless, in the first place, the self-consistency of logic is unable to add more content of reality to the theoretical hypothesis, other than that of being the formal product of a constructive course developed with a greater or lesser self-consistency. In the second place, not even a step has been given here towards the nature of the general real necessity, beyond its appearance of an abstract repetition. Or, even worst, the certainty concerning the content of reality of a theory is declared possible not by demonstrating the theoretical necessity in reality, but the necessity of reality through logic.

As a second option, Marxist scientific theory accepts that verifying its results is only possible as the foresight of main tendencies[13]. Still, it happens that these tendencies have no way of realizing themselves other than through concrete human action. And the action that realizes a tendency can appear as its very negation, inasmuch as the inverse relation may be possible. Let us recall that, 'all science would be superfluous if the form of appearance and the essence of things immediately coincided.'[14] Thus, the nebulous field that goes from the tendencies that are presumably known to the necessity of the concrete action that realizes them, is consecrated as the kingdom of opportunism, by the critical scientific theory itself.

Marxist critical theory seeks for the solution inside the theoretical procedure itself. It tries to solve the question of the certainty concerning the reality of theories through the immanent critique of theoretical developments.[15] Still, to be such, this immanent critique must follow the logical necessity even more rigorously than the criticized development. Therefore, deep as it may go into a theory, this immanent critique has no way of overcoming the externality of the logical necessity with respect to the real necessity.

Marxist theory does not know if its own impotency must horrify or fascinate it. In both cases it goes on by considering itself free from the hopeless problem of verification. In the first case, because it has decided that its truth criteria reside in its moral foundations, in the elevated aims that guide it.[16] That is to say, it presents itself necessarily constructed on the basis of a philosophy. We come thus face to face with the ideological negation of scientific cognition, i.e., philosophy, placed as the necessary departing point of the scientific cognition of reality. In the second case, this scientific theory directly declares any question concerning the truth or falsity of a theory to be meaningless. It starts by resolving that scientific cognition only deals with the mental forms through which it represents reality, but not with the real forms themselves. Hence, it declares eliminated by nature the necessity to confront the reality of the theoretical construction. From here on, it believes enough with declaring itself the working class' revolutionary doctrine, to sustain its cognitive superiority.[17] Thus, it can only end up by concluding that all which matters concerning a scientific theory is its usefulness towards promoting action.[18] What does not have to matter in the least to accept this complete emptying of scientific cognition, is that the action thus based can be anything but an action aware of its cause. We are dealing with an action that sees itself having no other aims than those it abstractly ascribes to itself.

As a last resort, Marxist theory vindicates practice itself as the instance that renders the verification of hypotheses possible.[19] Unfortunately, the realization of this verification presupposes the previous realization of the action. This position implies by itself that there was no way of knowing if the theory was true or false in the very moment that the action was performed; that is, when cognition really matters. Likewise, this fact uncovers the vacuity of the attempt to overcome the impossibility of verification by alleging that scientific theories are not 'predictive' but 'explicative.'[20] Thus pushed beyond any hope, Marxist theory tries to conceal this fact attributing the potential of verification, not to each concrete singular practice but, to an abstract social practice. Theory is verified, we are told, in the historical development of the transformation of reality accomplished by society on its basis.[21] Of course, any other ideological representation, e.g. religion, can make the same claim in its favor.

Of the critical intention merely remains the assertion that, just as the restraints to theory apply to natural science, the limitation of social theory to cognize reality insofar as it exists as a potency will asymptotically reach its resolution under socialism.[22] Or, otherwise, it merely remains the assertion that the very necessity of scientific cognition concerning social forms will be extinguished in socialism, on representing the overcoming of alienated consciousness as the possibility of wholly cognizing these forms in an immediate way;[23] as if socialism were not the supersession of the form of social organization which, in turn, has precisely emerged from the insufficiency of immediate cognition to carry out that organization. Thus, in both cases, the alleged critique even surpasses the modern successors of positivism when the time comes to elude the questions that today emerge in concrete practice from the non-verifiability of theories, by presenting these questions as matters of pure scholasticism.

In a nutshell, the point is that scientific theories cannot go beyond interpreting reality in different ways.[24] They are but ideologies. However powerful an action based upon a theory may be in its mission to transform reality, it is in itself the denial of the action which thoroughly cognizes its own necessity beyond any appearance, insofar as it is based upon an interpretation. No wonder theoreticians themselves end up condemning scientific knowledge, as a consequence of its logical method itself, to the field of 'exhausted utopias', of 'emancipating grand narratives;'[25] or, worse, to the field of the attempts of 'totalitarian domination,' aimed at oppressing human freedom.[26] This happens to the extent that the belief that the ideological determination of all scientific cognition must be taken for granted currently passes for the most unquestionable historically conscious criticism of its present general form.[27]

The contradiction is obvious. Any interpretation of a real determination is in itself the denial of the knowledge of that determination that has transcended every appearance; the interpretation of one's own need is the denial of its complete objective cognition. But the general conscious organization of social life entails that the objective knowledge held by each of the members of society about his/her determinations as such, transcending every appearance, becomes the general social relation. Therefore, as much as scientific cognition is condemned to interpretation, so the general conscious organization of social life is condemned to impossibility. In other words, as much as scientific theory is the final form of scientific cognition, so socialism/communism is condemned to impossibility. Even the most blatantly apologetic cretinism of capitalism has nothing further to request: from the mouths of the true representatives of scientific method comes the utterance that this very same method declares that 'the end of history' has been reached, that 'the future is already here.'

In addition, as scientific knowledge has been reduced to an ideological conception whose specificity lies in its repressive and authoritarian power, antiscientific irrationality and fragmented sight begin to earn praise as the liberating resistance that 'desire' opposes to oppressing knowledge[28]. Theoretical representation opposes the very denial of totally free action -i.e., the free interpretation of reality[29]- to the transforming power of totally free action –i.e., of the action that is aware of its own determinations beyond any appearance- as the consummation of human freedom. In scientific theory, ideology manifests itself in the form of its opposite, namely, scientific method.

The reproduction of the concrete in thought, i.e. dialectical cognition

The critique of scientific theory has no way of taking shape in the formulation of a new logical paradigm. In other words, the critique of the current universally dominant science does not take shape in the construction of a new theory, but in the production of a new form of objective cognition that supersedes scientific theory itself. Thus, it is not about conceiving a new representation of reality, condemned by its sole condition as a form of representation to follow a constructive necessity alien to the real one, to follow a logic.

What is to be done then? There is only one step possible: we must face the issue itself of 'what is it to be done' in a radical way; that is to say, we must start by submitting to criticism the determinations of our own transforming action from its very roots, from the determination of our social being, putting everything into question.

The production of the scientific consciousness of the working class concerning its own historic potential is not a mere scientific matter. It is a necessary specific moment of the political action of the working class within in class struggle. As long as the scientific consciousness of the working class remains the prisoner of the same method that operates as the scientific consciousness of the simple production of relative surplus value -namely, of logical representation- it lacks the capacity to uncover that, in the capitalist mode of production, freedom is the concrete form of alienation. Certainly, the working class makes its revolutionary advances based on this consciousness in the process of centralizing capital as a direct social property. Moreover, insofar as this advance necessarily entails the advance in its liberation from the rule of the bourgeoisie, it appears to be the practical confirmation that the theories it uses to rule its action are the product of a purely free consciousness. Nevertheless, the same production of relative surplus value forces forward the continued development of conscious control on social labor. This drives the conscious action of the working class towards overcoming any limitation that could be imposed on that control by stopping short at an appearance. Sooner or later in this process, the working class finds out that it is impossible to continue advancing without uncovering its own free consciousness as the necessary concrete form of its alienation as an attribute of capital. It can only take this step by appropriating its own determination which it achieves by reproducing their necessity in thought. That is, when its action concerning the conscious organization of social labor needs to leave behind it the exteriority of logical representation to govern itself through the reproduction of the concrete in thought.

[29] Rorty, Richard, *Philosophy and the Mirror of Nature*, Basil Blackwell, Oxford, 1980, p. 208.

At the point when we intend to appropriate in thought the necessity of our action, we are faced with the object of this action as it actually is for us in that moment: something external. We therefore are faced with our object in its immediate exteriority. We overcome the appearance of this immediate exteriority as we advance through the abstract forms of our object. The analysis pertinent to scientific theory separates the abstract forms according to their degree of repetition, therefore stopping at their exteriority. On the contrary, the analysis that is going to support the reproduction of the real necessity in thought separates the concrete form that we face from the necessity that it carries within itself as the other-one whose realization determines it. That is to say, it takes shape by discovering the abstract form (and as such, a necessity to be realized) within its concrete form (and as such, a necessity already realized). Given this form, the analysis cannot cease until it reaches the real form that does not carry in itself an other-one from which its necessity arises, but which is, by itself and not by an other-self, the need to negate itself as abstract existence in order to affirm itself as concrete existence. That is to say, until we face matter simply as such.

The return towards the concrete forms following the analysis that has come to a halt in the externality of the abstract forms unavoidably takes shape in the addition of the non-repeating -and consequently previously excluded- forms to the representation. This process lacks any necessity to follow other than the purely constructive one dictated by its logic. Hence, the inevitable externality of its result with regard to the real necessity that the action aims to realize. On the contrary, the reproduction of reality in thought advances by following the development of the necessity that the simplest abstract form carries within itself. As soon as this abstract form realizes its necessity, i.e., it affirms itself as an abstract form, it negates itself as such an abstract form in order to affirm itself as a realized necessity, i.e., as a concrete form. But this concrete form immediately negates itself as such, by affirming itself as a form that carries in itself a necessity to be realized, i.e., as a new abstract form. Thus, we follow in thought our real object as it unfolds its development. This reproduction of the development of real necessity by means of thought is unable to get to its end before reaching a form whose necessity as a potent power takes our transforming action -determined as an action that has needed to follow this path all along in order to become a conscious action- as its necessary form of realizing itself. That is, the reproduction in question is unable to get to its end until our action can discover its own concrete form as a conscious action, i.e., can discover itself, as the necessary concrete form of the realization of the real potential at stake. Due to the form of its method the ideal reproduction of reality is determined as dialectical cognition.

Science, i.e., the production of the objective consciousness, is thus carried out in a concrete form that immediately corresponds to its content: it has no room for necessities other than those purely inherent to its object. Therefore, when it is developed by the alienated subject, it unavoidably faces the latter with the evidence of his/her own alienation, whichever the appearance of abstract free subjectivity he/she has started from. Hence, the development of scientific cognition as the way of governing the transformation of present society into that of freely associated individuals is the critique of scientific theory.

The science of capital as the pure form of annihilating itself, namely, the science of the working class

The apparent separation between cognition and practice stems from the nature of the historical stage of humanity's development in which the regulation of the process of social metabolism by means of thought - the specifically human regulation of the process of social metabolism - is alienated, turning itself into a concrete form of the autonomous regulation of this process by the production of value. Only in this historical stage can scientific cognition appear denying its true immediate condition as the necessary form taken by the regulation of conscious action. Moreover, scientific cognition can even appear as the very denying of action, as its abstract opposite, in other words, as theoretical cognition. In the very form of its method, that is, as *dialectical cognition*, the reproduction of one's own necessity by means of one's thought immediately shows itself excluding all appearance of externality in relation to the action that it sustains. It shows itself, therefore, as what it is: the regulation of such action, that is to say, a specific portion of this action and, consequently, this action itself. Scientific research thus overcomes all appearance of being the abstract opposite of practice, to affirm itself as *practical criticism*.

Since it begins, unavoidably, by discovering its own historical condition as an alienated consciousness, dialectical consciousness can only be a product of capital inasmuch as the latter needs to annihilate itself through the conscious general organization of the social metabolism. Therefore, dialectical cognition as practical criticism can only arise as the immediate expression of the general interests of the working class; namely, as the expression of the latter's power to abolish itself as a class by constituting the society of freely associated individuals. Only inasmuch as it expresses this necessity is dialectical cognition able to advance upon the immediate concrete forms of the political organization of privately-performed social labor and of the transformation of natural forces into human instruments. Nevertheless, when it does so, it brings to these fields the revolutionary powers it obtains from its very historical reason of existence.

Given its primary determination, the production of dialectical consciousness initially has to take the form of a political action of the working class immediately aimed at this self-same production. Hence -from the viewpoint of capital ideologists, obliged to conceive of any form of scientific production as a process of logical representation- the production of dialectical consciousness seems to begin as a process of abstract theoretical production. Nevertheless, dialectical consciousness can only count on a single object in order to advance, even to take the first step in its development, namely, the action of the working class in its struggle against the capitalist class in order to express the immediate necessities of social capital. Therefore, the concrete object from which the development of dialectical consciousness must needs start in order to produce itself, makes this same immediate end inseparable from the true end of dialectical consciousness in present-day society: the general conscious organization of the action of the working class in the class struggle through which the capitalist mode of production annihilates itself in its own development. Far from being an abstract theoretical production, the production of dialectical consciousness, i.e., the conscious organization of one's action by reproducing its necessity in thought, is always, given the unity of its form and content, a product of the concrete political practices of the working class.

As a concrete form of the general social relation, the conscious organization of social life performed by dialectical cognition is necessarily a task for the collective laborer who is politically delimited by the advance in the transformation of his/her environment into a means for him/herself based on this same organization. This collective laborer only affirms him/herself in his/her unity as such with respect to the process of knowledge as long as all of those members in the collective process reproduce the whole of the necessity of each one's share in the collective action that, as such a member, he/she is going to perform. Consequently, there is no way for the collective laborer to include within itself the separation between the organization and the fulfillment -in a restricted sense- of each action; in other words, there is no way for the collective laborer to include within itself the separation between the knowledge of the necessity of the action and the execution of the action itself. In brief, the action governed by the form of dialectical cognition is the actual abolition of the separation between intellectual labor and manual labor.

Today, the action governed by dialectical cognition is a necessary concrete form of capital. In turn, capital is the very denial of the consciously organized process of social metabolism. Nevertheless, because of its mere objective form, dialectical cognition embodies, as its own necessity, that same necessity inherent in the process of consciously organized social metabolism: the necessity of being the product of freely associated individuals. Though, in the capitalist mode of production, individuals lack any way to become actually free other than by having an alienated consciousness that negates its own alienation; i.e., as the negation of the negation of their freedom. Even as the form of dialectical cognition necessarily determines the social subject able to develop it as an alienated subject which, due to its awareness of its own alienation is therefore free, this cognition makes evident that it is only a power of capital insofar as it bears its own annihilation through the development of the material conditions for the general conscious organization of society as a historical necessity. Only because it is thus determined by its specific form of reproduction in thought of reality as a class product, as the science of the working class, does scientific cognition free itself from any ideological determination.

Marx's advance towards conscious revolutionary action

Marx's *Capital* is in itself the development -performed for the first time and objectified in a way that enables its social reproduction- of the alienated consciousness of the working class that produces itself as an alienated consciousness aware of its own alienation and of the historical powers it derives from it. In *Capital*, this consciousness develops to the point where it reaches its general determinations concerning the revolutionary action of the working class in which the historical powers in question realize themselves, thus producing the material conditions for the conscious -therefore, free- organization of social life.

From Marx on, any process of cognition of this kind concerning social forms over which we need to act in a revolutionary manner is, in what is thus determined as its general part, a recognition process from the social point of view. Still, we can very well say that it is not about *reading Capital*; nor even about *studying* it. The point is to face capital's real forms by ourselves to ideally reproduce them, with the potency we acquire by having at our disposition their ideal reproduction developed in *Capital*. Actually, the development by oneself of this task is the only critical way to recognize the original specificity of Marx's procedure concerning scientific method. Any other way implies an attempt to unfold the real necessity that is present here in a mode external to it; therefore, it implies to represent this necessity.

While he develops the ideal reproduction of capital's necessity, Marx stresses the specificity of the method he has discovered, in his well known remarks on scientific procedure. For instance:

> It is, in fact, much easier to find by analysis the earthly core of religious mistiness than, conversely, from the real relations of life at each moment, to develop their celestial forms. The latter is the only materialistic and, therefore, scientific method.[30]

Of course, Marx's most famous comment on the matter is the so frequently quoted one where he directly describes the research method and defines its result as the reproduction of reality in thought:

> The concrete is concrete because it is the synthesis of multiple determinations, therefore, the unity of diversity. It appears in thought then, as a process of synthesis, as a result, not as a point of departure, although it is the true point of departure, and, therefore, as well, the point of departure of intuition and of representation. In the first path [the analysis], the sheer representation was condensed to abstract determination; in the second one, abstract determinations lead to the reproduction of the concrete by the path of thought.[31]

Nevertheless, Marx does not get to develop the specific difference between this scientific cognition that ideally reproduces the real necessity and theoretical cognition, that only represents it. In other words, he does not get to face this ideal reproduction as the critique - the supersession - of scientific theory itself. This happens to the extent that he refers to his own scientific works and discoveries as being of a theoretical nature. Certainly, in Marx's time scientific theory had not yet got to unfold its ideological determination as an apologetics of capitalism, no longer for its potency but, for its lack of potency to transform nature in full cognition of cause; that is to say, scientific theory did not yet need to boast about its own limits to consecrate the impossibility of the conscious regulation of social life. Marx was then able to advance for the first time in the ideal reproduction of the real forms of capitalist society until discovering its historical character, without confronting the necessity of making explicit the specific difference between that reproduction and theoretical representation, inasmuch as this difference embodies in the form itself of one and the other cognition process. Still, the sole materialization of this advance violently pushes scientific theory towards the exhaustion of its capacity for self-criticism in the complacency with respect to its own impotence. Today, the organization of the conscious revolutionary action of the working class immediately presents the form of the critique of scientific theory.

What does Marxism have to say about the specificity of the method discovered by Marx? We can hardly find a more expressive synthesis than Lenin's non less widely quoted assertion 'If Marx did not leave behind him a "Logic" (with a capital letter), he did leave the *logic* of *Capital*.'[32]

Let us briefly unfold the point once more. Reality, matter, has the self-affirming by means of self-negation - the necessity of self-determining, contradiction - as its general form. Hence, each natural concrete form (and therefore, each natural form specifically developed as a social one) is the realized necessity of its abstract forms in their becoming, from the simplest one (matter as such), to one that negates itself as such concrete form (realized necessity) affirming itself as a potency (a necessity to be realized). Cognition is the way in which a subject regulates the realization of its own potency as the necessary concrete form of realizing a potency inherent in its environment, by appropriating these two potencies in their virtuality as purely such potencies. The subject of the cognition by means of ideas always starts by facing its object as something external to itself as such subject. Under its simplest form, this cognition reaches the necessity of the subject's own action just insofar as this one virtually manifests itself to the subject's mind as an immediate link between the mutual necessity of the subject and the object. Consequently, such form of cognition does not go beyond the very exteriority of the subject and of its object. It is determined, thus, as *immediate* ideal cognition. This cognition develops into cognition by means of thought when the subject goes beyond the immediate concrete forms to discover their necessity as realizations of their abstract forms. Nevertheless, on performing this advance, the subject comes up, first of all, against the exteriority of the abstract forms themselves; that is to say, the subject starts by ideally facing the abstract forms in what these forms have of realized necessity, under their appearance as purely concrete forms. From which, the appropriation of a real necessity in thought takes its most primitive specific form by ideally placing by itself in a causal relation the real forms (abstract and concrete ones) starting from the way they present themselves to it; that is, by mentally conceiving links among the real forms on the basis of their exteriority; and, therefore, independently from their necessity. Cognition becomes a mental construction that follows a causality alien to the real one: the ideal *representation* of reality. Logic is the scientific general form of this mental necessity. The appropriation in thought of the real forms in their virtuality transcends the exteriority of these forms by ideally accompanying them in the unfolding of their real necessity. In this way, scientific cognition mentally reproduces their real concatenations, thus taking the form of an ideal *reproduction* of reality. This cognition has no way of proceeding other than by making each real concrete form account for the necessity that it carries in itself as an already realized one, and each abstract real form, for the development of the necessity to be realized which it is.

Reality simply is the self-affirming by means of self-negation. Dialectical cognition, *dialectics*, is the method for virtually appropriating this contradiction that reality is, by following its development with our thought. Seen the other way round, dialectics does not belong in reality but in human cognition of reality; or, rather, it belongs in reality, in matter, in what this one takes its specific form of human cognition. This same condition applies to logic. Still, while the former can only take shape following the development of the necessity of a concrete real form, the latter necessarily has to take an autonomous incarnation as a condition for representing any concrete real form. Hence, any attempt to call the ideal reproduction of reality a logic, even runs into a formal impossibility: the absence of an independent body of ideal relations able to receive such a name. To pretend that logic remains effective in the ideal reproduction of reality, it is necessary to abstract it from its formal and historical determinations, turning it into a pure abstraction.

The certainty about the need of a logic to appropriate reality in thought inevitably implies that the real forms are taken as if they were incapable of being the realization of their own necessity, as if life were to be insufflated to them by the cognition process itself. Representations, whether on an idealist or a materialist basis, cannot avoid carrying in themselves this appearance. Let us look at it a little closer. To assert the need of a logical necessity to apprehend in thought any real form means, by itself, to assert that this real form has no necessity of its own to be mentally followed: being there a real necessity, why should we appeal to a mental one instead of just following it through its development, with our thought? Hence, real forms appear as being unable to relate, to move, by themselves at the beginning of the representation process. But they emerge from this process overflowing with relations. Hegel just sticks to this appearance up to its end. He gives logic as its content, that is, as the content of the abstractly ideal necessity, the general form of the development in thought of the real necessity, placed not as the ideal reproduction of matter but as the development of the real necessity itself. Dialectics is thus inverted, appearing as the development of the Idea placed as the real subject that engenders matter. On doing so, Hegel pushed representation beyond its limits. The real necessity was laid there with its strength unchained, ready to be called into action. Naturally, standing dialectics on its feet after such inversion has nothing to do with entering 'matter' where Hegel writes 'idea' and vice versa.

Marx gives a first step in putting dialectics right side up by opposing to the claim of generality of Hegel's logic concept, 'the peculiar logic of the peculiar object'[33]. 'The peculiar logic of the peculiar object' already excludes by itself the possibility for logic to take a general body as the ideal necessity that cognition must follow and, therefore, its possibility to exist by itself. And what can the 'the peculiar logic of the peculiar object' be, but the reflection in thought of the development of the real object's own specific necessity? Nevertheless, Marx still has not completely developed here the distinction between the ideally produced necessity, the logic, that is, the discursive reason, that takes the place of the real causality in the representation and this real causality itself. It happens that Marx has not gone yet beyond the boundaries of philosophy; so much so, that he still identifies the abolition of the proletariat with the realization of philosophy[34]. But, immediately after in the same year, 1844, Marx faces for the first time the economic determinations of capital as the alienated general social relation of present-day humanity. On doing it, he discovers for the first time in history the real necessity of philosophy as a concrete form of alienated consciousness and how Hegel has developed it to its end. Consequently, Marx does no longer criticizes logic for being a general ideal necessity that displaces a peculiar ideal necessity. He criticizes logic for being an ideal necessity itself that displaces the real necessity that has to be followed in thought to rule one's conscious transforming action. That is, he criticizes logic for its very essence as a discursive reason that represents the real reason in thought, as the necessary form in which alienated thought takes shape:

> In turn, the philosophical spirit is nothing but the alienated spirit of the world that thinks inside its self-alienation, that is, that captures itself in an abstract way. *Logic* [the pure *speculative thought*] is the *money* of spirit, the speculative, the *thought-out value*, of man and of nature; its essence that has become completely indifferent to any real determination and which is, therefore, unreal; it is the alienated thought that hence abstracts from nature and the real man; the *abstract* thought.[35]

A little later, in 1847, Marx develops the specific critique of dialectical logic, showing step by step how this 'absolute method' starts from categories (that is, from the ideal representation of the real forms) and unavoidably ends up by representing itself as the one who engenders the real forms (Hegel) or by succumbing to its own contradictions (Proudhon)[36].

[35] Marx, Karl 'Pariser Manuskripte 1844' *Texte zu Methode und Praxis,* II, Munich: Rowohlts Klassiker, 1966.

Hegel's inversion is embodied in the form itself of the process of cognition; it is embodied in the conception of this process as a logical one. In fact, to proclaim logic as an inescapable condition for scientific cognition is nothing but to consecrate the idealist inversion, that prioritizes a mental necessity over matter's necessity. To say it once more, the question is not to give rise to a new logic, but to free science from it. Precisely what Marx has done. The claim for a logic in *Capital* is a contradiction in terms. This is something that Marx himself remarks in his comments on Wagner[37]. And, by the way, for the same reason there is not a single invocation in Marx to a dialectical logic, nor to a logic in general, there is not to dialectical materialism, to historical materialism or to other such *categories* either, that can only be used to *conceive* the real materiality and the real history as the corresponding abstractions.

Nevertheless, according to Marxism everything comes down to inverting dialectics again just by turning into a common place the representation of its development accomplished by Marx as its opposite, as if it were the development of a *dialectical logic*.

Engels points out how Marx made clear he was not a Marxist.[38] Considering what they call themselves, we must assume that Marxists can only see in Marx's assertion an expression of insincere modesty, or of his sense of humor, as Althusser wants to.[39] It happens that, opposite to Marx, *they really are* Marxists. As its very name shows, *Marxism* is the conception of the *reproduction* in thought of the specificity of present-day society - originally developed by Marx - as a *representation* of this specificity; and, hence, the representation of dialectical cognition as a *conception of the world*, as *a system of thought*. In brief, it is the degradation of the integral cognition of one's own necessity to *an interpretation* of reality and, therefore, to an *ideology*. The stage is reached where the point is turned into interpreting the world by interpreting Marx in different ways. It is not surprising then, that even though Marxism is always willing to point out the historical nature of capitalism and its concrete forms, the idea that scientific theory is one of these never crosses its mind. It is unable to recognize that, as it is a form of consciousness, scientific method is a social relation and, as such, a historically specific form. As we have already seen, it happens that in scientific theory, ideology takes the form of its opposite, of scientific method.

Thus, like any other scientific theory about present-day social forms, Marxism shows its own necessity insofar as a concrete form of alienated consciousness by representing itself as the abstract negation of alienated consciousness, as an abstractly free consciousness. But here it is where dialectic materialist logic shows the *raison d'être* for its specificity, for representing the simplest real determination, the self-affirming through self-negation, as the unity of two immediate affirmations mutually opposed and, therefore, for representing the existence of the concrete forms as abstractly opposed to their own determination. Marxism does not represent itself just as an abstract free consciousness, but, by invoking dialectical logic, it represents itself as the abstract free consciousness placed by itself as the opposite pole of the consciousness alienated in capital. Marxism does not see itself as being the opposite of alienated consciousness for recognizing itself as a form of existence of capital; on the contrary, it sees itself as the absolute realized negation of capital, as a social form whose necessity is external to capital. From this point of view, capital's historically immanent necessity of annihilating itself in its own development, that determines the working class as the necessary personification of this annihilation, comes down to an action external to that development itself. And, consequently, the performer of this action comes down to an abstract opposite of capitalism that, at best, has its necessity related to this one's as its absolute realized negativity, to the working class that reacts in self-defense against capitalistic misery and oppression.

[36] Marx, Karl *The Poverty of Philosophy* New York: International Publishers, 1963.

[37] Marx, Karl 'Notes on Adolph Wagner' *Karl Marx: Texts on Method* Oxford: Basil Blackwell, 1975.

[38] Letters to E. Bernstein dated 2-3/11/1882 and to C. Schmidt dated 5/8/1890.

[39] Althusser, Louis, *La filosofía como arma de la revolución*, Cuadernos de Pasado y Presente 4, Córdoba, 1972.

As a result, the revolutionary realization of socialism/communism does no longer appear as what it is, as the realization of the historical necessity of the general regulation of the present-day process of social metabolism (and therefore, as the ruling itself of this process in action), as the realization of the historically own necessity of today's general social relation. On the contrary, the working class' revolutionary action sees its necessity degraded to the realization of 'right', 'justice', or 'equality' as opposed to capitalist 'unnatural' injustice and exploitation;[40] to the realization of the 'dialectics of ethicity';[41] to the 'increase of an internal self-determination or self-morality';[42] to the fact that the mere antagonistic relationship that exists between the exploiters and the exploited in class struggle engenders an abstract accumulation of experience;[43] to the 'autonomy' achieved by class struggle with respect to its determination as the necessary concrete form of the socialization of private labor;[44] to the 'autonomy achieved by the working class' consciousness with respect to capital, be this -in relative terms- by means of the production of a revolutionary 'doctrine',[45] or by means of its 'self-valorization';[46] to the 'democratization' of capitalism through the apparent standoff between an abstractly free consciousness and an abstractly alienated consciousness by means of 'market socialism';[47] to the production of a working class consciousness able to develop itself by itself beyond the exhaustion of the development of productive forces;[48] to the need to avoid 'barbarism' vis-à-vis the mechanical impossibility of capital reproduction;[49] to the resistance of the laboring surplus population in its desperate struggle to survive. In brief, the working class' revolutionary action sees its necessity degraded to a collection of abstractions that cannot but ideologically reflect the alienation of human potencies as capital's potencies, but that are represented as being so naturally eternal that the society freed from all alienation could only be realized through them.

Opposite to this naturalization of an abstractly free consciousness, the point is the conscious organization of the revolutionary action of the working class through which capital realizes its necessity of annihilating itself into the general conscious organization of human life. Therefore, the point is to produce an alienated consciousness that is aware of its own alienation or, in other words, to produce an alienated consciousness, indeed, but one that is only such insofar as it is the negation of the negation of free consciousness. The advance in the production of this consciousness is the concrete political task of the working class that expresses its general historical interests. Moreover, this production is, in itself, the process of the determination of the forms that correspond to the organization of the political party of the working class that directly bears the power of the capitalist mode of production to overcome itself.

As Marx shows, the point is not to interpret the world. The point is that the transformation of the world in question is the development of the conscious organization of the process of social metabolism, and, therefore, the supersession of interpretation itself. Above all, the scientific critique of scientific theory is the development of the organicity of the working class' revolutionary action.

Transformations in capital accumulation: From the national production of an universal labourer to the international fragmentation of the productive subjectivity of the working-class

Transformations in capital accumulation:
From the national production of an universal labourer to the international fragmentation of the productive subjectivity of the working-class

Juan Iñigo Carrera

1. The starting point

The revolutionary action of the working-class needs to organise itself through the awareness of its concrete determinations. Since we are focusing on a process characterised by international integration and fragmentation, it could seem that the most concrete approach is that circumscribed to the economic policies that prevailed in the different national processes of capital accumulation involved.[1] Still, this approach ends up by bringing down all historically-specific necessity to the immediate action of those that personify capital. Thus, apologetics of capitalism presents national capitalists and state-bureaucrats as the social subjects whose abstract will rules the historical movement.

Opposite to this sterility it could seem that the starting point lies in capitalism's global unity, once this unity is represented as the movement of accumulation regimes, their rise, 'failure' and fall. Still, then, the subject of historical change seems to have vanished, as if this were 'a process without a subject'.[2] Once again, abstraction has displaced the concrete.

It could seem, then, that the answer lies on circumscribing the global unity of accumulation to its concrete manifestation: class struggle. Still, considered in itself, class struggle comes down to a series of confrontations in which, now the working-class prevails and advances, now it is defeated and retreats, at the rhythm imposed by the development of working-class consciousness. Thus, consciousness appears as that which determines by itself the working-class as an historical subject.[3] Even the most concrete form is turned into an abstraction when it is separated from its determinations.

Human natural history consists in the history of the transformation of the material conditions of social life through labour. The development of the human being as a historical subject is but the development of its capacity to act in a conscious and voluntary way over the rest of nature, to transform it into a means for itself. In other words, it is the development of human productive subjectivity. This development is the only concrete materialistic, and therefore the only scientific[4] starting point to produce the consciousness about any historical movement. Therefore, this will be our starting point here, to unfold the concrete determinations of the current transformations of capital accumulation and its present crisis.

Machinery and productive subjectivity

The accumulation of capital based on the production of relative surplus-value through the machinery system transforms the materiality of the labour-process. It gradually ceases to consist in the application of labour-power upon the objects in order to transform them. Rather, it turns into the application of labour-power to scientifically control natural forces and to objectify this control in machinery, in order to automatically apply those forces upon the objects to transform them. Accumulation thus determines in three ways the productive subjectivity of the labourers in large-scale industry.[5] In the first place, it degrades the productive subjectivity of the labourers that still apply their labour-power to the direct transformation of the objects. It simplifies their work, turning them into the appendages of machinery or into detail labourers in modern manufacture. Secondly, it transforms an increasing part of the working-class into a surplus-population, thus directly depriving it of its productive subjectivity. Thirdly, it develops the productive subjectivity of the labourers in charge of advancing and exercising the scientific control over natural forces, enabling them to perform an increasingly complex labour.[6]

Accumulation under its classic national form

The accumulation of capital is a global process in essence, but a national one in form. Let us start with the countries where accumulation presents the concrete national form that most immediately reflects the unity of its essential determinations (hereafter, 'classic countries'): Western European countries and the USA. During the 19th century and through the first three-quarters of the 20th century, capital accumulation presented a noticeable tendency concerning the reproduction - therefore exploitation - of labour-power. The labour-power whose productive subjectivity underwent degradation and the one whose productive subjectivity expanded tended to be reproduced jointly and under relatively undifferentiated conditions. This unity had a general technical basis.

The labourers of degraded productive subjectivity lack the opportunity to develop any skills in their labours. Still, the more complex the collective production processes that include their simplified individual labours become, the more they demand the application of universal productive aptitudes whose development escapes from the mere practice of those individual labours. Likewise, these labourers must be able to adapt themselves to any machinery imposed by technical change. Therefore, capital needs to produce them as universal labourers before they enter production, however degraded their participation in it. And this previous formation needs to be extended inversely to the possibility of developing a particular productive skill in practice and directly to the frequency with which capital forces the workers to move from one task to another. In addition, the intensity of labour imposed by the pace of machines and by the scientific improvement in the manufacturing division of labour requires a shorter working-day.

---

[5] As it modifies the materiality of the labourers' productive subjectivity, capital modifies the scope and content of their consciousness. It is not that the labourers' consciousness is functional to capital. Functionality would mean that the labourers' consciousness arises beyond the capital-relation itself, and then, this externally formed consciousness adapts itself to capital's needs. Contrary to this apparent externality, the labourers become really subsumed in capital through the production of relative surplus-value (Marx 1965, p. 510). Even as working-class, they are the attributes of capital (Marx 1965, p. 573), that produces and reproduces them as human beings, ie. as bearers of consciousness (Marx 1965, p. 578). Their consciousness is inverted - under the appearance inherent in circulation that they are free individuals - into the powers of capital, ie. of their own objectified general social relation that has become the alienated concrete subject of social life. The revolutionary action of the working-class is the necessary concrete form in which the above-mentioned constant revolution in the materiality of the labour-processes - that concurrently entails their direct socialisation - develops its necessity to be organised as a direct social power that transcends the boundaries of its capitalist private form. Therefore, this revolutionary action is the necessary concrete form through which the capitalist mode of production realises its historical necessity to overcome itself through its own development by engendering the general conscious organisation of social life.

[6] In *Capital*, Marx developed the first two subjectivities, but he referred to the third one only indirectly (eg. Marx 1965, pp. 386-87 and 508-09). Thus, a gap could seem to appear between the degradation and loss of productive subjectivity and the constitution of the working-class' capacity to consciously organise social life. Yet, in *Grundrisse* Marx presented the latter subjectivity as the one whose materiality directly bears the necessity of capital to annihilate itself through it own development. (Marx 1973, pp. 704-07). In Marx's time, the subjectivity in question was only just starting to develop. Nowadays, accounting for its development is the key to any revolutionary program of the working-class (Iñigo 2000b).

In turn, the production of labour-power that bears an expanded subjectivity is based on the production of a scientifically structured productive consciousness.[7] Therefore, it is based on the expansion of the universality of the labourers' productive attributes. These labourers require a longer universal and particular scientific formation of their labour-power before being able to enter production. However, this labour-power only achieves its complete maturity after several years of being actually applied. In the early 19th century, English capital optimised its valorisation by exploiting workers whose natural lives it exhausted in thirty years. Nowadays, the labourers bearing the most developed productive subjectivity, the scientists, only become mature enough to produce surplus-value when they reach this age. Hence, capital needs to extend their useful-life, to dilute their training costs and to fully exploit their aptitude to perform complex labour. The conditions needed to achieve this extension extend the labourers' natural lives beyond the exhaustion of their productive attributes. Besides, it becomes a cost for capital when the labourers lose their productive aptitude because of illness or circumstantial unemployment. The value of labour-power thus includes pensions, medical assistance and unemployment compensations.

The expansion of productive subjectivity does not lie on the multiplication of either handicraft skill nor physical strength. It concerns, above all, the development of the labourers' productive consciousness. It is about constantly pushing this consciousness beyond the limits reached by the control over the natural forces already objectified in machinery. The point is to develop the capacity of the labourers to make productive decisions by themselves in the name of capital. The consumption of use values that corresponds to the reproduction of this labour-power is consequently determined in quantity and quality. In turn, the intensity of labour involves the fixation of the labourers' attention in the process of productively deciding. This demands a shorter working-day.

Both the materiality of their labour and of their individual consumption reinforce in the consciousness of these labourers the appearance of being free individuals, who dispose of what is their own for an equivalent, in pursuing their self-interest. Hence, that unitary materiality reinforces the appearance through which the exploitation of the labourers as forced workers for social capital, paid by it with the product of their own former unpaid labour, and whose individual consumption is not for themselves but for capital, takes concrete shape in circulation. So much so, that the more these labourers develop their productive subjectivity, the harder they find to recognise themselves as what they are, namely, members of the working-class.

In brief, albeit rooted in the divergence of their productive subjectivity, the reproduction of both types of labourers converges towards a certain degree of relatively common universality.

During the above-mentioned period, the lower birth rate (that corresponds to the transformations in productive subjectivity), plus both the pace of capital accumulation and of the increase of its technical composition, the shortening of the working-day, massive emigration and periodic slaughters in war, ended up giving the local labouring surplus-population a peculiar appearance. It did not seem to transcend being a floating one, on a massive scale. And, in this case, social capital needed to maintain its productive subjectivity to place it back in action in due time. Thus, the illusion emerged concerning capitalistic accumulation having freed itself from its general law: that which makes the accumulation of social wealth in the pole of capital an accumulation of misery and degradation in the pole of the working-class.

---

[7] The divergent paths followed by the labourer's productive subjectivity directly reflect the historically-specific determination of the division between manual and intellectual labour when the social powers of labour are developed as the alienated powers of capital in large-scale industry. From the standpoint of productive subjectivity, this division is focused as it directly concerns the labourers' activity as the subjects of the labour process alienly ruled as a valorisation process.

Under these conditions, social capital found it cheaper to undertake the relatively undifferentiated and massive reproduction of the working-class that included the two opposed productive subjectivities. The general political representative of social capital, ie. the national state, was in charge of this task. The reproduction of labour-power thus acquired a specific expression: that of public education, health, pensions, unemployment insurance, housing, transportation, etc. Hence, the labourers reproduced themselves under conditions that individually reached them as an expansion of their equal rights as citizens of the nation. In this way, that which the working-class pays for with its own surplus-labour to reproduce itself as a forced labour-power for capital, and that it necessary achieves by struggling against the bourgeoisie, appeared ideologically inverted as the gracious concessions that the 'welfare state' granted it.

Nevertheless, the inversion of the political forms on the basis of the relatively undifferentiated reproduction of the working-class through the direct action of the political representative of a national social capital reached a further expression yet. It did so as this reproduction converged with the necessity of reproducing the national process of capital accumulation through the centralisation of individual capitals as immediate units of national social capital and, therefore, as state capital. The most developed form of this inversion arose when the centralisation in question needed to reach the totality of the capitals that underwent valorisation within the country in order to start to realise its powers. This centralisation could only take the concrete political form of a social revolution that abolished the domestic private fragmentation of capital. In other words, it presupposed a social revolution through which the working-class and the peasantry expropriated the bourgeoisie and the landlords, and imposed the collective property on capital and land within the national boundaries. Yet, capital has not ceased to be such because it has been thus centralised. It goes on confronting those that are now its owners as an alien power that dominates them. The national state became then, not only its general political representative as social capital, but also the direct agent of its accumulation in production and circulation through its immediate movement as individual capital. Because of its political concrete form, this process realises itself under the appearance of being its very opposite, ie. realised socialism or communism. That is the case of the USSR.

The Appendix shows the evolution of the conditions of exploitation in the UK and the USA during the period considered, concerning real wages, length of the working-day, education and productivity.[8]

---

[8] As it could be seen in the Appendix (albeit distorted by the inclusion of productive and unproductive labour for capital in the computation), the productivity of labour has been steadily multiplied throughout the development of great-scale industry. Insofar as this multiplication has taken place in the branches that directly or indirectly produce the means of subsistence for the workers, the values of these means of subsistence have been falling in consequence. Nevertheless, an important part of this cheapening has been sterilised as an immediate source of relative surplus-value. The individual capitals that introduced the technical innovations have appropriated in a normal way the extraordinary surplus-value that emerges from the possibility of selling below the social value but above the individual value, by individually putting into action a productivity higher than the social one. In turn, as the new technical conditions have been generalised and the social value has turned to be determined by them, the means of subsistence for the workers have become cheaper. Still, this cheapening has been significantly compensated by the necessity of a higher consumption of use values to reproduce labour-power with the productive attributes required from it by capital, given its new general technical conditions. At the same time, the increased intensity of labour that corresponds to these new technical conditions has been imposing the necessity to shorten the working-day in a significant way. Therefore, the increase in the surplus-value rate that the constant revolution in the productivity of labour potentially carries in itself has been restricted to the net balance between the cheapening of the means of subsistence, on the one hand, and the increased consumption of means of subsistence and the shortening of the working-day, on the other.

Handicraft skill in the machinery system and workers' political power

Along with the conditions seen thus far, the labourers whose productive subjectivity declines attained political strength from an historically-specific base to impose on capital their reproduction in conditions close to those of the labourers whose subjectivity expands. The labourers' handicraft skill still stood at the very core of the production based on the machinery system, ie. in the production of machinery itself. Capital had not yet freed its valorisation from it. The calibration of the machinery for serial mechanical production remained subordinated to the labourers' handicraft skill. The same happened regarding the assembling process, however much that skill came down to the simplest operations through the manufacturing division of labour. The assembly line was yet not a true machine; the eye-brain-hand unity still ruled the tools.

Concurrently, the scale of capital accumulation placed those labourers together at work in large masses. Furthermore, the very material conditions of their labour process, devoid of content and controlled in an openly coercive way, made them immediately confront capital as an antagonistic alienated power. The sum of these conditions directly gave the portion in question of the working-class the consciousness of precisely being working-class. Consequently, the direct mediation of its subjectivity in the production of machinery became a particularly powerful weapon in its struggle against the bourgeoisie to realise the value of its labour-power. Moreover, it led the reproduction of the rest of the labour-power bearing the same productive attributes but that was placed in a non-central place concerning the general productive structure of large-scale industry.

However, in a violently visible manner since the mid-1970s, the computerised calibration of machinery and the robotised assembly line - finally turned into a machine itself - revolutionised the production of machinery. Upon which, both automations revolutionised the general conditions of capital accumulation based on the machinery system. The productive subjectivity based on the labourers' handicraft skill started to be expelled from the production of machinery. As far as it remained there, it did so only by descending in its degradation as an appendage of the machinery. Conversely, capital needed to strengthen the development of the subjectivity able to advance in the productive control over the natural forces. This control had gone a step beyond as the only resource to increase the productivity of labour and, consequently, to produce relative surplus-value.

Capital thus deprived the first portion of the working-class of its specific source of political power. At the same time, it needed to reproduce the second portion with an expanded capacity to perform complex labour. Thus, capital doubly eased its necessity to produce the two portions under relatively undifferentiated conditions. Moreover, it needed to cheapen one, extend its working-day and shorten its preparation in a brutal way, whilst it needed to take the other down the opposite path. Still, it could not perform this divorce at once. Both portions reached this point coming from a common history: that of their relatively undifferentiated reproduction through the action of the national state that integrates their members as citizens bearing equal rights. It could seem that the national form taken by accumulation rose a barrier against it. Yet, that very form carried the solution within itself.

Latent labouring surplus-population and cheap degraded productive subjectivity

Outside the classic countries, an increasing portion of the peasantry had been displaced from production and transformed into a latent surplus-population by capital accumulation. Its birth rate rose, to enable social survival over the weakened possibilities of individual survival. Thus, capital accelerated the expansion of this surplus-population from both ends.

The international separation between the active labouring population and the surplus one necessarily stems from the realisation of the global content of accumulation through independent national processes. The expansion of the labouring surplus-population to the point of characterising a country expresses the pure development of that content. Yet, capitalism apologetics inverts the relation between global content and national form. On doing so, it presents that expansion as if it were the result of the 'underdevelopment' of capitalism in those countries.

On internationally separating the active labourers from the latent surplus-population, the national form of accumulation politically fragments the working-class. On this basis, capital was able to break the barrier contrived by the history of relative productive universality conquered by the labourers in the classic countries. It did so by technically dividing the processes of production along national borders. The parts of these processes in which the expanding productive subjectivity dominates, tended to remain on this side of the border. On the other, the latent labouring surplus-population was turned into an active labour-power. Albeit, one which basically performed the tasks that require a productive subjectivity lowered to absolute simplification as an appendage of the machinery and as a detail organ in manufacture.[9] The conditions in which this latter part of the working-class was exploited were no longer the concern of the national state where capital exploits the former. Now, they just came to concern the citizens of 'another country'.

Still, not all the latent surplus-population generated beyond the borders of the classic countries was equally apt as a source of labourers bearing a degraded subjectivity.

Capital had engendered a mass of latent labouring surplus-population in Latin America. Nevertheless, it still found it profitable to valorise itself there based on its association with landowners to appropriate the agrarian and mining differential rent. To gain access to this valorisation, capital needs to detach fragments of itself in the classical countries, to put them into action as small capitals of a magnitude specifically restricted to the scale of the internal market, in the countries where the rent is appropriated. Therefore, this modality of valorisation excludes production for the world market - beyond the commodities bearing ground-rent - from the latter countries, and limits the capacity to import from it.[10] Hence, capital waited until this form of accumulation pushed surplus-population a stage forward, before turning it into a source of degraded productive subjectivity nationally differentiated.

In Africa, accumulation had turned former hunters-gatherers, shepherds and farmers of unirrigated lands into latent surplus-population. This population was not accustomed to large-scale collective labour ruled by a central authority. Since it was unfitted for its needs, capital just went on consolidating it as a surplus. Thus, capital even deprives it of its capacity to transform its environment into a means for itself through labour, sentencing it to death.

Quite different was the history of the latent surplus-population in East Asia. Former free peasants, harshly exploited via a strongly structured tributary and rental system, constituted it. This modality of exploitation had its general material basis in the presence of irrigated agriculture organised on a large scale. Hence, these peasants were used to intense, collective and disciplined labour, performed under their immediate responsibility as free individuals, but hierarchically ruled in a general way. Their history made them particularly apt to be transformed into labourers able to function as appendages of machinery and in modern manufacture.

---

[9] Fröbel, Heinrichs and Kreye 1980. However, labelling this separation a matter of 'core' and 'periphery' obscures its true content that arises from the differentiation of productive subjectivity. The so-called peripheral labour-power is as 'core' to present-day capital accumulation as any other.

[10] Iñigo 2000a.

The national process of capital accumulation in Japan

The international division of labour according to the type of productive subjectivity prevailing in each country started to resort to the historical attributes of East Asian rural population before automation reached the point of imposing it.[11] The particular origin of Japanese labour-power here comes in. Contrary to the classic countries, the national working-class was not universally reproduced under the conditions imposed by the necessity to expand productive subjectivity. Rather, the expanded subjectivity was able to be produced even under the conditions that simply corresponded to the reproduction of the degraded one.

On this basis, simple labour already started to move from the classic countries to Japan in the 1950s. However, this displacement could not reach the labour that produced machinery itself. The material base that diluted the political strength of the labourers that performed it in the classic countries had not yet developed. The displacement could only start with a type of production where the handicraft skill of the labourers prevailed, but that lacked itself any essential role in the general development of the productivity of labour. Japan became, then, a large-scale producer of apparel and footwear for the world market.

Nevertheless, accumulation moved forward in the classic countries. Productive subjectivity became able to control the microelectronic processes. Then, it was not just a question of producing automatic machines where this control became objectified. It was about producing them by means of equally automated machines. Yet, to automate the calibration of the machinery and to robotise its assembling, the electronic components bearing automation had to be assembled first. Therefore, capital freed itself from the intervention of the labourers' handicraft skill in the mechanical processes of calibrating and assembling at the expense of resorting to a new manual labour process: the assembling of electronic components. This circumstance appeared to counterbalance the political weakening of the working-class in charge of simplified assembly labour. Still, capital had the international division of labour based on the history of each national labour-power at hand.

The assembling of microelectronic components constituted a new operation. Therefore, in the classic countries where the complex labour of research and development started to be performed, a collective labourer that amalgamated the latter with simple assembling labour had not been consolidated at this moment. Potentially, the working-classes of the classic countries could acquire new political strength were that collective labourer constituted within those countries. Yet, this constitution appeared to them as being a decision of capital. Hence, they faced their own potential political empowerment as an alien potentiality. Capital did not need to start by defeating the national unity of the collective labourer in question. It sufficed with putting the assembling of the microelectronic components in the hands of Japanese labour-power of degraded productive subjectivity, which was relatively cheap given its specific history. Furthermore, in Japan, this relative cheapness included the labour-power of expanded productive subjectivity too. Capital utilised the latter to perform research and development that completed the task of the new applied microelectronics collective labourer. This labourer had been finally constituted, based on the Japanese national specificity.

---

[11] It has been debated if it is about the social capitals of the classic countries imposing a new international division of labour or about the social capitals of the 'new industrialised' countries imposing themselves on the world market (Jenkins 1984). Both sides invert the necessary national forms through which the generic global unity of capital accumulation rules social production, by presenting them as the unity itself of accumulation.

Nevertheless, the production of automatic machinery includes a task that demands an expanded productive subjectivity plainly reproduced as such. This task involves the mental labour needed to create and develop the logical structures that control the flow of electronic processes itself. Its materiality specifically determines it as the attribute of labourers that reproduce their labour-power under conditions that feed in their consciousness the appearance of being abstractly free individuals. Therefore, it collides against the conditions of reproduction of a working-class whose specific productive powers arise from its immediate historical origin as a peasantry subjected to labour under a hierarchical and authoritarian rule. Furthermore, if this happens concerning the labour applied to the mere development of logical structures, with all the more reason it happens concerning the labour that develops the scientific capacity itself to advance in the control over natural forces, ie. basic science.

In Japan, research and development labour has been mainly aimed at the technological application of science. Such an immediate scope has manifested itself in the social organisation of scientific and technical production mainly through disbursements realised at the risk of individual capitals.[12] Any revolution in the productivity of labour stems from the development of basic science. Its pioneer application becomes a particularly powerful source of extraordinary profit. However, its productive results normally fall beyond the scope of individual capitals. The same occurs concerning the concentrated capital required for its development. Therefore, its general production is necessarily ruled via the direct disbursement of social capital through the state's political action. International fragmentation thus has even concerned the expanded subjectivity itself as the classic countries have tended to monopolise the above-mentioned labour processes.

Thus, by the mid-1970s, capital had already formed the collective labourers in charge of automating the calibration of machinery and its assembling as subjects fragmented by a first international division of the productive subjectivity of their members.[13] Likewise, capital had also internationally fragmented the collective labourers in charge of producing the machinery itself. The productive subjectivity of the labourers that apply their handicraft skill to calibrate and assemble machinery had lost its critical intervention in the production of the machinery system. To the extent that capital continued to need it - and the very same automation multiplies this necessity by simplifying existing tasks and by creating equally simple new ones - it tended to be exercised by labourers reproduced in conditions that strictly correspond to their specific attributes.

Accumulation flourished in Japan, already including the production of machinery, cars, electronic equipment, etc. for the world market. The opposite occurred in the classic countries. The old fixed capital could no longer sustain valorisation. It was not just a question of technical obsolescence. Its inability stemmed equally from being located in countries where the value of labour-power corresponded to its reproduction with the relatively universal material and moral attributes that tended towards the general development of its productive subjectivity. The crisis of general overproduction detonated in the classic countries.

The fragmentation of the working-class within the classic countries

The reproduction of labour-power in the classic countries suffered substantial changes. Crisis threw labourers that worked in the now obsolete conditions into the industrial reserve army. This enabled the bourgeoisie to break the unity of the national working-class regarding the process of determining the value of labour-power. An increasing differentiation in the reproduction of the respective labour-power of degraded and expanded subjectivity replaced the tendency towards a relative universality. The latter tendency necessarily took shape through the political and trade union advances of the working-class. These advances were then expressed through the direct action of the national state that reached the bearers of different labour-powers as citizens bearing equal rights. The reversion towards relative differentiation took the opposite shapes.

---

[12] Okimoto and Saxonhouse 1987.

[13] Jang-Sup Shin 1996, p. 113.

Trade union power stepped back, unable to resist capital's charges to intensify the exploitation of the labourers bearing a degraded subjectivity. Of course, capital did not miss the opportunity offered by an increased industrial reserve army, to intensify the exploitation of the labourers bearing an expanded subjectivity too. Thus, while the average real wage (direct plus indirect) arrested its increase, the gap between high and low wages deepened. See the Appendix, particularly for the USA.

The retreat from the relative universality in the reproduction of the labourers of large-scale industry became specifically apparent though the political defeat of the working-class. Through crisis, the national state advanced on that which appeared as the equal rights of its citizens, imposing the individual capacity to pay for as their new expression. The reversion towards the separation in the reproduction of the different fragments of the national working-class took shape through privatisation[14] and the reduction of public expenditure in health, education, unemployment, etc. If capital accumulation appeared thus far as being subjected to the 'intervention' of the so-called 'welfare state', its general political representation now appears as naturally inhering in the 'neo-liberal state' that worships 'the market'. Now the labourers have to reproduce their labour-power on the basis of a wage that individually corresponds to their specific productive subjectivity.

European and American social capital has introduced the differentiation in the conditions of reproduction and exploitation of the working-class even when its members are determined as equal citizens of the same national state. Nevertheless, it has needed to go further in deteriorating those conditions concerning the labourers of degraded productive subjectivity that it requires in the countries where the developed subjectivity prevails. To attain such a differentiation, it has needed to transplant inside the national ambit the separation between the two types of labourers on the basis of their different national citizenship.

In Europe, this differentiated integration has developed through the gradual formation of a new national ambit of accumulation - and hence of a new national state - that starts by integrating formerly autonomous national ambits in a supranational organisation. The European Union includes national working-classes bearing different histories with respect to their productive subjectivity. Under the political form of an extended equality among their citizens, some countries of the union supply relatively cheap labour-power to the capital located in others. At the same time, the relative dissolution of each national unity allows an exacerbated regional and local differentiation in the internal reproduction of labour-power. In the USA, the immediate co-operation of national labour-powers bearing different productive histories has taken shape through free-trade agreements that run over the geographically common borders: the NAFTA.

Above these particular forms, immigration is the consummate path for differentiated national integration. Immigration reproduces national boundaries as a difference of citizenship within the working-class that capital exploits within a country. Capital moves what is a latent surplus-population in its original country, to the country where it needs it as a labour-power bearing a degraded subjectivity that complements the local one, mainly reproduced to bear an expanded subjectivity. Far from acting as an egalitarian factor among the conditions to reproduce one and the other labour-power inside the same country, citizenship rises here as a justification for inequality. The miserable conditions in which the immigrants reproduce their labour-power politically appear as not being the concern of the receiving national state. They are not its citizens. Capital extremes the differentiation by resorting to the two-faced policies of massive illegal immigration. At the same time, racism, xenophobia, religion, etc. develop into the necessary concrete forms taken by the differentiated reproduction of both productive subjectivities within the same country.[15]

---

[14] Concurrently determined by capital centralisation beyond national spaces.

These transformations did not fit at all the capital absolutely centralised as a property of the working-class within the USSR. This capital could not detach fragments of itself to valorise them in another country without violently colliding with the appearance - necessary for its general valorisation - of being the supersession itself of the appropriation of surplus-value. Even domestically, this appearance would ha been destroyed by the accelerated expulsion to surplus-population that such a detachment would have meant to the soviet working-class. Essentially, this type of national process of capital accumulation is restricted in its expansion beyond its borders to international trade, regardless if on a free basis or through direct coercion. Likewise, this capital cannot accumulate itself by deepening the differences within the working-class that owns it, violently pushing a part of it into disqualification and pauperism, while at the same time it increases the mass of use values received by the other part. The concentration of capital as a collective property inside the USSR had shown to be such a powerful modality to enhance the national process of capital accumulation as to place it second in the world scale. Still, now its turn arrived to crudely show its own limitations vis à vis the world character of the powers of the capitalist mode of production. It thus went down into a violent process of capital decentralisation and national fragmentation.

As this happened in the classic countries and the USSR, the reproduction of labour-power followed the opposite path in Japan. Accumulation exhausted the latent surplus-population. And the more labour-power becomes the product of accumulation itself, the more the conditions for the reproduction of the individual labourers are ruled by the attributes that correspond to their productive subjectivity as organs of the collective labourer of large-scale industry. The reproduction of the expanded productive subjectivity could no longer be based on the conditions that corresponded to the reproduction of the degraded one. At the same time, the national unity of the process of accumulation imposed the extensive and intensive expansion of the former subjectivity. The conditions for its reproduction became the ones that those corresponding to the degraded subjectivity tended to follow. The Japanese working-class advanced in its political and trade union struggle to improve the sale of its labour-power. See the Appendix.

New sources of latent labouring surplus-population

The automation of machinery and its robotised assembly are processes in constant progress. Consequently, they go on simplifying the labours performed as appendages of machinery and in modern manufacture. Simplified labours can be performed by further unskilled, therefore cheaper, labour-power. At the same time, the increased labour productivity and intensity achieved through them constantly cheapens the commodities produced in the automated plants compared with the similar ones produced by the labourers' handicraft skill. What once was a labour-power cheap enough to counteract the low productivity and intensity it rendered loses this attribute vis-à-vis the once and again increased productivity and intensity of the labour performed by a labour-power that formerly was too expensive. From both sides, accumulation imposes the constant relative cheapening of the labour-power bearing degraded productive subjectivity.

---

[15] Apparel industry synthesises this differentiation (Blumenberg and Ong 1994).

As soon as Japanese labour-power became relatively more expensive, capital started searching for a renewed national source of latent surplus-population that it could transform into an industrial army bearing a degraded productive subjectivity. Again, it found the specific history of the East Asian former peasantry to be particularly appropriate. By the late 1960s, the simplest labour processes started to move from Japan to Taiwan, South Korea, Hong Kong and Singapore. Again, apparel and footwear marched ahead.

International fragmentation of productive subjectivity and differentiation in the capacity to accumulate

To internationally relocate production, capital needs to move itself bearing a certain concentration. It must reach in its new location the scale required to compete by producing for the world market. Thus, the accelerated expansion of production had presupposed an accelerated accumulation and individual concentration of capital in Japan. Given this accelerated nature, plus that of being a national process of accumulation that confronted the classic ones on the world market, the unity of individual capitals as the aliquot parts of national social capital became visible with specific immediateness. That is, the Japanese state acted in a particularly visible manner as the direct agent of the accumulation of individual capitals. In turn, the same necessity to accelerate accumulation imposed an immediate unity between industrial and bank capital. Hence, the concrete forms taken by the accelerated accumulation in its unity as a national process became completely apparent in the Japanese case.

When the production based on cheap simple labour expanded to other East Asian countries, the concrete forms of accelerated accumulation shed new light on their specific contents. These contents became the basis on which each national process of accumulation has developed its own specificity. To begin with, in Taiwan, the expansion of production has been characterised by the proliferation of small capitals.[16] The question that must be addressed is why, being about producing cheap commodities in large-scale for the world market, did capital fragment itself into individual units whose restricted scales normally mean higher costs?

Accumulation rules itself by determining individual industrial capitals as aliquot parts of social capital through the formation of the general rate of profit. Only industrial capitals bearing the scale needed to put in action the productivity of labour that determines the value of commodities actively participate in that formation. Industrial capitals that fall behind in the process of concentration are unable to go on autonomously operating as such. They are forced to become capitals lent for an interest. Nevertheless, they can delay this shift. The general rate of profit no longer rules their valorisation in an immediate way, but through the - normally lower - interest rate. Therefore, they can remain active as small industrial capitals insofar as the lower concrete rate of profit that immediately rules their valorisation counterbalances the higher costs caused by their smaller scale. The selling price thus determined cannot exceed the price of production, but the opposite relation is possible. In this case, on selling at the price of production, small capitals would appropriate an extraordinary profit placed above their specific normal rate. Yet, small capitals cannot avoid competing over the extraordinary profit, making it flow to the normal capitals that relate to them in circulation.

---

[16] Fields 1998.

In turn, normal capitals cannot compete with each other directly for the extraordinary profit they are thus receiving. They would not only lose it, but mutually destroy their capacity to valorise at the general rate of profit. Hence, the extraordinary profit in question becomes a constantly reproduced inflow for the normal capitals that appropriate it through the concrete circumstances of circulation. For instance, this is the specific relation established between a capital concentrated in the normal scale needed to design a certain commodity and to impose its social necessity through advertising, and the bunch of small capitals that produce it. That is the true content of what political economy inverts by presenting the market-forms as the cause of the different concrete capacities to accumulate.

The cheapening of labour-power is the key to the international fragmentation of the working-class' productive subjectivity. However, for the highly concentrated capitals, it comes together with the extraordinary profit that the direct exploitation of the labourers bearing a degraded subjectivity by the small capitals, frees for them. Besides, because they stand on the edge, small capitalists are particularly appropriate to exercise the merciless exploitation of those labourers. Normal, ie. sufficiently concentrated, capitals reserve for themselves the pretty face of 'human relations'. This is a condition to extract surplus-value from the part of the working-class whose productive subjectivity concerns the conscious control on the natural forces. But what about direct production taking place under miserable conditions, that include physical abuse on children, as the source for 'pretty face' capitals' extraordinary profits? 'That' is not 'their business'.

Still, not all productions based on a degraded productive subjectivity can be competitively performed by small capitals. In large-scale industry proper, the simplification of labour presupposes highly concentrated constant capitals to which massive collective labourers are attached. This happens in the car, heavy-machinery, shipbuilding, steel, etc. industries. Hence, to internationally move these productions in search of a renewed source of cheap labour-power, a concentrated movement of capital has to take place. In this sense, the original centralisation of capital in steel industry and, moreover, of bank capital as national state property is the starting point for the specificity of South Korean accumulation.[17] Small capitals are present too. Yet, capitals concentrated in a scale aimed at competing in the global formation of the general rate of profit prevail.

As we have already seen, the relative cheapness of the expanded productive subjectivity in Japan did not suffice to massively move the complex labour devoted to basic research there. As the simplest labour moved to the continent, the international fragmentation of productive subjectivity cut complex labour in a specific way again. It reached technological research itself. To a certain extent, this part of the labour process did not go beyond Japan.[18] Basically, it is the simple labour applied to production in a restricted sense that moved to the new countries.

When that fragmentation runs between independent individual capitals, it delimits a second difference concerning the concrete capacities of accumulation. Each time a technical innovation rises the productivity of labour, the individual capitals that lead its use appropriate an extraordinary profit. Still, this extraordinary profit disappears as the new technique is generalised. Now, the more the capacity to control the natural forces develops into the general basis of production in large-scale industry, the more the production of this development itself becomes a special branch of social production. The products of this branch bear a peculiarity: that of giving access to an extraordinary profit for the capitals that consume them. This circumstance entitles the capitals of the special branch in question to a share in that profit. Of course, this share vanishes as the new technique becomes generalised. Then, the capitals that consume the innovation have to wait until they exhaust the useful life of the fixed capital where the innovation is embodied, to renew their chance. Oppositely, the capitals whose product consists in the technical innovation itself renew the source of extraordinary profit with every renewal of their production process. The development of the productive subjectivity aimed at controlling the natural forces thus turns into a regular source of extraordinary profits for the individual capitals specialised in it. When sellers and buyers of innovations are systematically separated by an international border, a continuous flow of extraordinary surplus-value from the consuming country to the producer one occurs. Thus, the attempt to produce its own scientific and technological development becomes an immediate condition for the expansion of the national process of capital accumulation in the former. Yet, to achieve that development, the corresponding productive subjectivity must be developed within the country first. And this development normally means a relatively more expensive national labour-power, thus undermining the basis on which the national process of accumulation immediately stands.[19]

---

[17] Pilat 1994.

[18] Smith 1997.

Worse still, the prices of the commodities exported owing to the cheapness of the national labour-power present a particular tendency to fall. They become cheaper, similarly to any other, as the productivity of labour increases. But they become cheaper, too, because this increased productivity is put in action by a labour-power that is constantly cheapened through the incorporation of new latent surplus-population. This incorporation reaches Thailand, Malaysia, the Philippines and Indonesia since the late 1970s. This time, electronic components themselves integrated the vanguard. Furthermore, the incorporation of Bangladesh, Sri Lanka, etc followed in the late 1980s. Nevertheless, the conditions of accumulation in the region were truly revolutionised as Chinese latent surplus-population started to function as a cheap source of simple labour to produce for the world market. This incorporation characterised the 1990s.

Chinese latent labouring surplus-population appears as an inexhaustible source of labour-power apt to function as an appendage of machinery and in modern manufacture. The cheapness of this labour-power even contrasts with its primitive cost in other Asian countries. (See the Appendix). This cheapness, together with Chinese labour discipline, have a historical specificity that reinforces the regional one. In China, the process that transformed the peasantry into a latent labouring surplus-population was, at the same time, the process that reconstituted the former centralised national unity of the organisation of social production. This unity is now established through a tendency to the absolute centralisation of capital within the nation, under the necessary concrete political form pointed out with respect to the USSR.

Chinese national social capital thus acquires the specific power given by the ideological identification of the workers with its accumulation. Moreover, any resistance they could oppose to the extraction of surplus-value they are submitted to appears inverted, here, as an attack to the socialist organisation of production. Hence, it appears as a treason to the historical interests themselves of the working-class. The national state charges against the workers' resistance with all the strength it gets from this appearance.[20]

The expansion that national accumulation is thus potentially able to reach, cannot wait for the mere expanded reproduction of existing capital. It demands a massive inflow of foreign capital. At first, the same political form taken by the national process of capital accumulation limited this inflow to foreign credit conceded to state firms. Yet, when the march itself of accumulation dissolved the apparent incompatibility between its national political form and its true content, capital started to flow as foreign direct investment.

[20] Reiitsu 1982, p. 241.

Towards general overproduction by means of the international fragmentation of productive subjectivity

Let us place ourselves in the early 1990s. The international division of labour is no longer simply based on the supply of raw materials to the classic countries, by countries where natural conditions allow a higher productivity of labour. Its contemporary specificity lies in the international fragmentation of productive subjectivity in large-scale industry. Some countries concentrate the exploitation of the labour-power bearing an expanded productive subjectivity. Others mainly concentrate the exploitation of labour-power bearing a degraded productive subjectivity. Finally, a third type of country essentially functions as reservoir of the labouring population that capital has deprived of all productive subjectivity, thus turning it into a consolidated surplus-population. Apparently, the 'globalisation' of production runs over national boundaries. Actually, it stands on their reinforced existence as the basis to cheapen labour-power.

Let us consider the aggregate evolution of West Germany, France, Italy, UK, USA, Japan, South Korea and Taiwan, between 1973 and 1992.[21] These economies synthesise the key to the transformation in the global exploitation of the working-class based on the international fragmentation of productive subjectivity. Gross domestic product at constant prices (that roughly reflects the evolution of material production) rose 68 percent, and total working hours 15 percent. The difference between both rates makes evident the increase in productivity, both concerning production and circulation labour. In turn, average annual hours worked per labourer fell 7 percent. Hence, the total number of employed labourers rose 24 percent. To hell with the disappearance of the working-class! The increase in the number of workers, plus the relative development of productive subjectivity and the exhaustion of agrarian origin as a source to cheapen labour-power, made the mass of real wages (strictly, the real direct plus indirect labour costs) rise 55 percent.

Let us assume that all labour-power at capital's disposal would have been that reproduced in the European and American conditions. To achieve the same increase in production, the number of jobs would have increased 47 percent, and the mass of real wages 65 percent. And notice that we are disregarding the fact that the reproduction of the labour-power in question has not escaped being deteriorated by the actual presence of the differentiation. Thanks to the international fragmentation of productive subjectivity, capital has appropriated a greater proportion of the material product of labour and turned more of the labouring population into a surplus one.

A part of the increased product covered the increase in the technical composition of capital: the mass of means of production and circulation to be advanced per working hour increased 88 percent. Yet, since this increase essentially corresponded to the expansion of fixed capital, an increase of 39 percent in annual gross investment sufficed to cover it. In brief, while production has increased 68 percent, the cost of labour-power has gone from representing 72 percent to representing 67 percent of it. In turn, the part demanded to replace and expand the means of production and circulation has fallen from 25 percent to 21 percent. However much the individual consumption of the capitalist class could have increased, the transformation suffered by the conditions of accumulation has advanced in a defined direction: general overproduction.[22]

This advance towards overproduction has not been an immediate expression of the law of the tendency of the rate of profit to fall. In the USA, the concrete annual rate of profit of social capital rose sharply after its fall during the 1930s, reaching a post-war peak in the mid-1960s, fed by the relatively undifferentiated reproduction of labour-power and the increased productivity achieved through it. Yet, as the value of labour-power started to be determined through the fragmentation of its reproduction according to each productive subjectivity, the capital whose technical attributes and location were associated to the former undifferentiated conditions started to become redundant. Then, the indifference in the reproduction of productive subjectivity started to appear as the cause of the fall of the rate of profit. Yet, it was just the concrete manifestation of the moral depreciation of the capital that corresponded to the former conditions.

---

[21] The sources are included in the Appendix.

[22] It is not about underconsumption. In capitalism, everyone consumes what one's general social relation - capital accumulation - rules one should consume; albeit this certainly means zero consumption for the consolidated labouring surplus-population.

Capital started to face general overproduction in the only way it knows: by fleeing directly into it. Credit is the tool for this. Selling on credit to an insolvent buyer creates the appearance that the capital materialised in the overproduced commodities has completed its circuit of valorisation. This appearance allows the renewal of that circuit in a scale expanded beyond the reach of the effectively realised surplus-value, by buying on credit too. As soon as credit reaches maturity, it acquires an independent life. The process of deferring overt general overproduction by expanding it now includes the renewal of mature credits, while interests accrue to unpaid capital. The 68 percent increase in production from 1973 to 1992 has been sustained by a 156 percent real increase in public indebtedness plus private indebtedness with the financial system. From 1992 to 2000, the product increased 26 percent more, at the expense of a 48 percent increase in indebtedness.

The apparently autonomous expansion of credit has a natural offspring, speculation. Credit titles start to function as fictitious capital. Fictitious capital is unable to valorise by itself. Still, here, its profits are fed by the constant flow of part of the unrealisable surplus-value, that constantly enlarge its base. In turn, fictitious capital inflated by speculation turns into industrial capital, thus fuelling overproduction. As capital advanced in the classic countries by exploiting the increase in productivity through automation, and the cheapening of labour-power through the latter's international and domestic differentiation, while at the same time it resorted to the expansion of credit, the rate of profit started to rise (See the Appendix). Yet, the more capital expands production to appropriate the thus increased rate of profit, the faster it advances towards general overproduction.

While the US and the EU entered a decade of expansion, in East Asia overproduction started to be evident despite the continuous expansion of credit. Japanese accumulation had practically exhausted the source of its specific strength (See the Appendix). It delayed an acute crisis of general overproduction, but overproduction goes on reproducing itself with the strength evinced by a continued general stagnation. South Korea, Taiwan, Singapore and Hong-Kong started the decade as the main substitutes for Japan on the world market, based on their relatively cheap labour-power. Still, when China imposed the extreme relative cheapness of its labour-power, overproduction became evident in the former countries.

The overproduction of industrial capital engenders fictitious capital. Or, in other words, unrestrained speculation is but the autonomous way in which the development of general overproduction of industrial capital rules itself. Now the time arrives for the true determination to appear inverted. It starts to seem that the excess of fictitious capital obstructs the accumulation of industrial capital. Still, the true fact is that the mere reproduction of the apparent valorisation of fictitious capital needs to be fed by an increasing flow of surplus-value, while it has gone beyond the capacity of industrial capital to support it with its unrealisable surplus-value. Thus, it seems that the insufficiency of the rate of profit detonates the crisis of fictitious capital. In turn, the latter depresses the capacity to pay and consume. It thus appears as engendering general overproduction by itself, albeit it does but to show that accumulation is approaching the necessity to re-establish its material unity through a general crisis. Now, overproduction does not come down to the existence of capital under obsolete material forms, either for their technology or for their location with respect to the international differentiation of labour-power. Simply, too much capital bearing the modern conditions of production has been produced. The time has arrived for the rate of profit to fall in the classic countries themselves.

Working-class internationalism

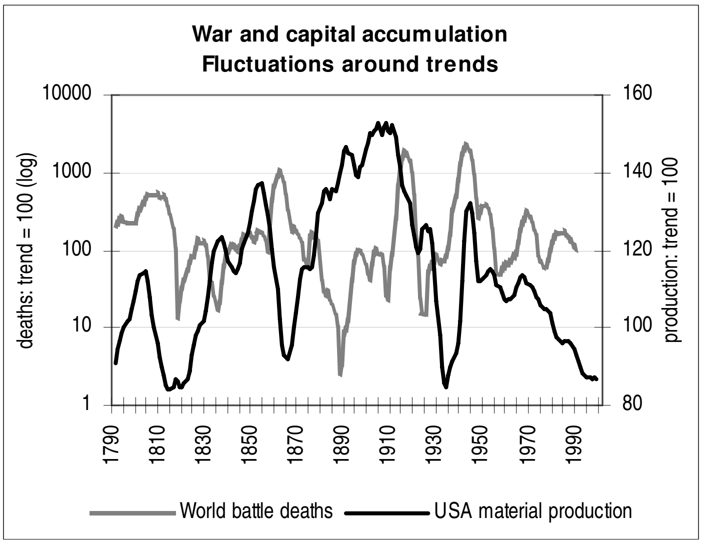
The automation of machinery and the robotisation of assembling are two genuine expressions of the historically-specific powers of labour under the rule of capital. They imply a substantial leap forward in the development of the productive forces of society under the material form inherent in the specific historical role of the capitalist mode of production; namely, through the transformation of labour into a process of collectively developing the conscious control on the natural forces to make these forces act on the objects to transform them. Still, as an alienated product of social labour, this leap forward turns against its own producer, the working-class. Standing on it, capital acts against its historical tendency towards reproducing the labourers of large-scale industry under universal conditions. It does so by internationally fragmenting the corresponding collective labourers, so as to link the different productive subjectivities of its specialised organs to the different historical conditions in which each national labour-power is reproduced.

On this basis, capital reproduces the labour-power whose productive subjectivity it degrades by spending just that which is required according to its specific attributes, thus cheapening it. By so doing, capital increases the rate of surplus-value. However, this increase does not result from developing labour productivity and, hence, the productive forces of society. Worse still, the cheaper labour-power becomes, the bigger the gap that the productivity of labour has to overcome before the machinery that supports it could be put in production. Therefore, the cheapening in question procrastinates the development of social productive forces. Moreover, the resulting lower mechanisation is far from counterbalancing the cheapening of labour-power with an increased demand for it. On the contrary, since the lengthening of the working-day is key to that cheapening, this process entails lower employment. A larger consolidated labouring surplus-population is yet another of its disastrous results.

Through the national form taken by its accumulation, capital divides the working-class into fragments that confront each other as citizens of different national states. This division is the specific political form through which capital differentiates the reproduction of labour-power according to the specific productive subjectivity it requires from it. Moreover, capital profits from the exacerbated international competition it imposes between the national fragments of the working-class through that differentiation. A specific task is thus imposed on working-class internationalism.

It is about forcing the reproduction of labour-power on a common universal basis, whichever its productive subjectivity. Capital cannot avoid reproducing the part bearing the developed one by paying it for its value. Therefore, an universal basis means that this would tend to be the general one. The consequent expensiveness of labour-power bearing degraded productive subjectivity would force capital to accelerate technical development. Hence, capital would be forced to cease avoiding its specific historical role in the development of the material productive forces of society.

The struggle of the working-class for the universality in the reproduction of labour-power has a necessary general political form: that of imposing a global undifferentiated citizenship. Therefore, it is not just about reinforcing international solidarity, but it is essentially about directly advancing towards the constitution of a world state.[23] The political action of the working-class needs to be, as ever, at the vanguard of the abolition of national boundaries. Yet, the general crisis of overproduction, increasingly required by capital to restore its material unity, will violently worsen the conditions of exploitation of every portion of the working-class. Historically, this has acted against working-class international unity. We cannot overlook the fact that capital has relied on generalised war as a key path to finally unleash, and afterwards also to overcome, its general crisis of overproduction:



Source: Iñigo Carrera, Juan, "Crisis, ciclos y tendencia de la acumulación de capital", CICP, Buenos Aires, 2002.

Furthermore, today, the perspective points to capital violently freeing itself from any burden that the consolidated excess of labouring surplus-population - globally distributed through the international fragmentation of productive subjectivity and expanded by the crisis of overproduction - could mean to its accumulation. The concrete forms of internationalist action towards an unmediated global working-class is the core question underlying any political action able to express 'the interests of the proletariat as a whole'.

---

[23] Hardt and Negri (2000) claim for a global citizenship brought down to the free international mobility of labour-power. This implies to believe that the national form of capital accumulation - hence national states - could be abolished by abolishing the immigration laws in which that national form itself takes concrete shape. And all this in the name of ethics, ie. of the alienated consciousness who sees itself as an abstractly free one. Contrary to such an idealist fantasy, world citizenship can only arise from the concentration of capital in scales and conditions that go beyond the scope of any national space, thus imposing the necessity of the world state as its general political representative.

The Historical Determination of the Capitalist Mode of Production and of the Working Class as the Revolutionary Subject

Juan Iñigo-Carrera

Downloaded by [Baskent Universitesi] at 07:45 23 December 2014

Prominent Marxist theoreticians conceive the working class as a revolutionary subject based on moral or ethical superiority, a natural will for freedom, self-valorization, the need to avoid barbarism, etc. From a materialist viewpoint, human history consists of the transformation of the material conditions of social life through labor. Capitalism is the historically specific development of human subjectivity by transforming the powers of free individual labor into those of the social labor consciously organized by the collective laborer who privately performs it. Thus, the material product of the labor of the working class increasingly consists of the development of its capacity to scientifically organize production, whereas this capacity goes on confronting it as an alien social power embodied in that same product, that is capital, that falls beyond its control. With its free consciousness thus embodying alienation, the working class carries this absolute contradiction inherent in the socialization of private labor (a contradiction that transcends the contradiction between social production and private appropriation) beyond its limit, until revolutionarily organizing labor as a direct social power. As a historical social relation, freedom is transformed by this revolutionary transformation of the materiality of labor: the absence of personal domination based on the objective consciousness concerning one's own individuality as the bearer of productive social powers annihilates the absence of personal domination based on submitting to domination by the social powers embodied in the product of one's own labor.

The Issue

The last quarter of a century has been shown to be particularly hard on the powers of the working class to change society. There where the working class had expropriated the expropriators, the power it acquired seemed to have turned against itself. This power vanished, leaving behind a working class ready to be exploited once again as an extremely inexpensive source of labor power. Things went no better for the working class in other parts of the world. Defeated time after time, it has seen the deterioration of its working conditions which it won after such fraught struggles. Furthermore, its own political parties have competed with the neoliberals in seeing which was most successful in forcing it to retreat.

The situation did not improve for the working class when, weary of party bureaucrats, it turned for support to the theoreticians critical of capitalism. First, the working class was informed that it had lost its condition as the subject able to transform society, since this transformation was a process without a subject.[2] Then, the working class came to know that the subject had been reinstated, but that it was no longer considered for this role. Far from being the result of the development of universal subjects, social revolution now sprung from the affirmation of a universe of subjects that only had in common their self-vindication as pettily exclusive identities.[3] Furthermore, not only did it have to discover that it was no longer the revolutionary subject, but that it did not even exist: work had disappeared, and so had the working class itself.[4] Later, it emerged that it was not work per se that had disappeared, but the private form in which it was carried out in capitalism. The forced worker for capital was now a 'social worker',[5] and the working class was itself invited to celebrate the loss of all identity and to live the joy of becoming a 'multitude',[6] or a 'civil society.'[7] And what about seizing power? Not even in dreams. The issue, it is claimed, is not

about the working class seizing in its own hands the powers of human labor alienated as powers of capital, but that capital itself will be quashed by mere indifference.[8]

And yet there is more. Nowadays, the barest reference to necessity, to a historical *raison d'être*, is a scandal and abomination to many of those that proclaim themselves critics of capitalism. Teleology![9] 'Exhausted utopias'! 'Grand narratives of emancipation!'[10] Or, worse, attempts of 'totalitarian domination'![11] Such are the sentences passed on any scientific recognition that society advances towards a certain direction. Under the umbrella of pluralism and diversity, all potential for social transformation is reduced to abstract 'desire', 'free will', or 'moral superiority', alien to any development of the materiality of the productive forces of society. No wonder theoreticians themselves end up claiming that poetry, religion and science attain equal rights as practical forms of consciousness in transforming all that exists.[12]

Nevertheless, from the point of view of the supersession of the capitalist mode of production the question remains unchanged: what is to be done? Since the aforementioned issues confront the condition of the working class as a revolutionary subject at its very roots, the only possible answer is to tackle the question of what is to be done by the working class in a radical way. This means starting by taking a critical stance in the face of one's own transforming action from its very roots, from the simplest determination of the social being of the working class.

The Social Being of the Working Class: Free Consciousness as the Concrete Form of Alienated Consciousness

Human natural history is the history of the transformation of the material conditions of social life through labor.[13] The development of the human being as a historical subject is nothing but the development of human capacity to act in a conscious and voluntary way upon the rest of nature, in order to transform the latter into a means for human life. In other words, the development of the human being as a historical subject is the development of the human condition as the subject of production, that is, of human productive subjectivity. This development is the only materialistic concrete starting point, and therefore the only scientific one[14] to generate consciousness as regards any historical process.

The capitalist mode of production starts by dissolving any general direct organization of social labor based on relations of personal dependence, thus turning

the producers into free individuals. Each concrete element of social labor is thus given the specific form of private labor performed independently from the rest. Then total social labor-power is allocated to its useful concrete forms through an autonomous system. As it is performed in a private and independent way,[15] the abstract socially necessary labor (a simple productive expenditure of the human body in whatever concrete form it is performed,[16] and, as such, a natural condition for human existence whatever the social modality that rules it)[17] acquires a historically specific social form. After it materializes into its products, it appears represented as the aptitude of these products to relate to each other in exchange, thus placing their private and independent producers within a social relationship.[18] That is to say, materialized privately performed socially necessary abstract labor is represented as the value that determines use-values as commodities.[19]

Since they need to generate their general social relationship through material production, the free individual consciousness and will of the producers that privately and independently organize their social labor are subjected to a historically specific determination. They have to submit to the needs that the value-form of their own material products imposes on them. They must act as personifications of their own commodities; they need to produce value as a matter of life or death. Commodity producers are free from any personal servitude because they are the servants of the social power of their products. Whereas it is the will of the producers that completely dominates the private and independent exercise of individual labor, these same producers are in turn completely subordinated to the social powers of the material product of that self-same labor. From the point of view of the participation of private and independent producers in social labor, their consciousness and will matter only inasmuch as they personify the powers of their commodities. The productive power of their social labor stands removed from the producers themselves as an alienated power, as a power incarnate in their commodities. The free consciousness and will of commodity producers is the specific form within which their alienated consciousness and will exist.

Now, at the same time, only because they are submitted to the domination of commodities, human consciousness and will determine themselves as free from all alien personal domination. In the previous modes of production, starting with primitive communism, there were no individuals freed from relations of personal dependency in the organization of their social labor. Those who stop at the appearances of the circulation of commodities believe that their possessors are abstractly free subjects by nature. Nevertheless, human freedom is but a social relation that in its historical development up to today has only existed and exists under the concrete form of not being submitted to relations of personal dependency because one is submitted to the social powers of the product of labor. Hence, the development of freedom has no necessity other than that that could emerge from the development of its very alienation.

[17] Karl Marx, *Capital*, Volume I, op. cit., p. 71.

[18] Karl Marx, *Capital*, Volume I, op. cit., pp. 72–74.

[19] Karl Marx, *Capital*, Volume I, op. cit., p. 38.

Therefore, social production is not directly aimed at producing use-values, but at producing the general social relation itself, that is value. In its condition as the objectified general social relation that represents the privately and independently performed social labor, value takes the substantive form of money. Money represents all the concrete modalities of social labor and, therefore, it embodies the potentiality to set into motion all of the modalities that will act as the starting point of the process of social metabolism. Thus, the organization of social production simply does not start from the alienated consciousness of each free individual putting in action his/her part in social labor. On the contrary, alienated consciousness does but express the necessity of the substantive social relation, which puts in action social labor without having as its immediate objective the production of use values, but the expanded reproduction of the very same substantive social relation. Hence, it is about the valorization of value, about the production of surplus value. Such is the capitalist mode of organizing social production. Capital is but the specific historical form in which the capacity to organize the labor of society gets into action as the attribute embodied in a thing that has been produced by previous social labor, with the immediate objective of producing more of that capacity to organize the labor of society as an attribute embodied in the material product of previously performed labor. Capital thus becomes itself the concrete immediate subject of social production and consumption.

As free independent individuals, wage laborers enter their general social relation as personifications of their only sellable commodity, their labor power. This means that the working class has nowhere from which to obtain any historically specific revolutionary powers other than those it gets from its own general social relation, namely, the production of surplus value. To be precise, the history of the production of surplus value is nothing but the history of the production of the material revolutionary powers of the working class and, therefore, of its revolutionary consciousness and will.

The working class constitutes itself as such through its necessarily antagonistic relationship with capital in terms of selling its labor power at its value. Nevertheless, the development of its revolutionary powers is not limited to the development of the formal subsumption of labor to capital. Through the production of relative surplus labor—that is, making labor power cheaper by multiplying the productivity of the labor that produces the worker's means of existence through a continuous technical revolution—labor really becomes subsumed under capital.[20] Even in their unity as working-class and in their very process of individual consumption, the workers become an attribute of capital.[21] Thus, capital produces and reproduces them as

human beings; that is, as bearers of consciousness.[22] This happens to the point that capital even rules the laws of their biological reproduction.[23] In the circulation of commodities, the consciousness of the laborers appears to be free. In fact, the consciousness and will of the laborers are defined as the necessary concrete forms taken by the alienation of labor's powers as capital's powers, namely, their own objectified general social relation that has become the alienated concrete subject of social existence.

The Capitalist Transformation of the Materiality of Labor and of the Laborer

Capital constantly revolutionizes the material conditions of production in the pursuit of relative surplus value. This revolution is not merely limited to the kind of a necessary large-scale collective process involved in working in mechanized big industry. As the system of machinery is developed, so capital tends to revolutionize the very material nature of labor. Essentially, labor ceases to consist of the conscious exertion of human strength and ability applied on tools in order to make them act upon an object to transform its use value. Rather, it tends to consist of the conscious expenditure of human body applied to the scientific control of natural forces and to the objectification of this control as an attribute of machinery, so as to make those natural forces automatically act upon tools in order to make the latter bring about the transformation of the object.[24]

Consequently, commodity producers are collective individuals (formed by doubly-free workers, both in the sense of not being submitted to anyone's personal domination and of being separated from the means of production required to produce their existence that confronts them as an alien social power) who perform their labors in a private and independent way. As independent private producers, these collective producers have complete control of their individual labor processes, but none at all over the latter's general social character. Therefore, their consciousness and will as collectives formed by free individuals must needs submit to the rule of the social powers of the material product of their labor, that is, capital: they must produce surplus value. The free consciousness and will of the members of the collective laborers are the concrete forms of their consciousness alienated in capital.

Capitalist Universality and Fragmentation of the Workers' Productive Subjectivity

The capitalist mode of production tends to determine laborers as social subjects whose freedom develops as the materialization of their own labor processes—which is governed in an alienated way—necessarily tends to transform them into the bearers

of a scientific, that is, objective, therefore, free, consciousness that aims to acquire an universal scope. And, as capital moves forward by eliminating the particularities that correspond to the direct application of labor power on its objects from the actual materiality of the labor process, it moves forward by universalizing the attributes of labor power; which means that it moves forward by universalizing the conditions of its reproduction, that is, the attributes of human consumption.

Nevertheless, the capitalist mode of production performs this transformation inasmuch as the conscious organization of social production is, at the same time, the necessary concrete form through which its opposite is able to realize itself. That is to say, inasmuch as conscious organization is the necessary concrete form in which the alienation of the productive powers of human labor is realized under the shape of an attribute of its own material product converted into the general social relation. In other words, inasmuch as it is about the socialization of private labor. Therefore, capital can only develop the universal powers and needs of the subjects of social labor through their opposite, namely, by constantly holding back and atomizing the universality of labor power. By privately socializing labor, capital revolutionizes the materiality of the labor process at the expense of the fragmentation of social labor power by determining the productive subjectivity of the laborers of large-scale industry in three contrasting ways.

Capital first needs to develop the productive subjectivity of the segment of the working class that participates in the collective laborer as the bearer of the latter's capacity to make progress towards universal control on natural forces and towards conscious control on the collective nature of labor. In itself, the development of this productive subjectivity reveals the general trend inherent in the historically specific development of the productive forces of society under the capitalist mode of production. Nevertheless, this does not mean that capital is moving forward without further ado. On the contrary, to begin with, capital itself constantly balances out its own historical general trend, thus turning each advance in the area of control of the natural forces into an objectified attribute of the machine. This means that any form of labor that exerts the aforementioned control becomes simplified, from the manual to the intellectual. At the same time, in the process of expanding its alienated productive subjectivity, the collective laborer broadens his sphere of action by taking charge of his self-coercion and the general representation of capital. The general antagonistic relation between those that personify labor power and those who personify capital permeates the collective laborer and, hence, the working class itself. The individual laborers that are in charge of those tasks appear both to themselves and to others as the very negation of that which they are; namely, members of the class of free individuals that only count on their labor power as a sellable commodity, that is, forced laborers for social capital, members of the working class. Consequently, even the part of the working class determined by capital as the direct bearer of the development of productive subjectivity suffers from the fact that its capacity to become aware of its own orientation as an alienated subject of social production is stunted. Therefore, capital prevents this part of the working class from fulfilling the very historic potential for which it was created by capital itself: the development of the productive forces of society through the objective conscious organization of social labor. This mutilation of objective consciousness—which takes the shape of its opposite, alienated consciousness—can only be embodied in the very form taken by the scientific method that produces it. Hence, it can only arise from scientific method, being, at the same time, the requisite concrete form of its opposite, that is, ideology.

Secondly, the system of machinery degrades the productive subjectivity of the laborers that develop and use their manual skills in the direct process of production. They become mere appendages of the objectified control of natural forces, i.e. appendages of machinery. Their labor is thus continuously disqualified, deprived of any content beyond the mechanical repetition of an ever-increasingly simplified task. Each leap forward made by capital in the process of appropriating natural forces, that is, each leap forward made by the productivity of labor through the development of machinery, means that capital expels this type of laborer from the direct process of production on a wide-scale basis. And it does the same to those detail laborers still bound by the division of labor in manufacturing. It replaces the necessary intervention of their skillful subjectivity in the direct process of production with the objectified capabilities of a machine. Nevertheless, at the same time that each technical leap forward expels this type of living labor in order to replace it with dead labor, it generates a multiplicity of new areas for its exploitation. These areas emerge precisely as a result of this new step in the degradation of the productive attributes of both types of laborers. Consequently, the development of the productive forces of society ruled by the production of relative surplus value through the use of machinery carries within itself its own negation. It does so by multiplying the working population that it needs to reproduce with an ever-deteriorating productive subjectivity rather than by developing its productive subjectivity.

Thirdly, capital accumulation based on the extraction of relative surplus value by means of the system of machinery transforms an increasing part of the laboring population into surplus population with regard to the necessities of capital. Capital is the general social relation of the laboring population, i.e. the general social relation through which the working class reproduces its natural existence. Therefore, to be transformed into a surplus for capital means to be deprived of the capacity to produce one's own natural existence. Thus, capital extracts up to the last trace of productive subjectivity from the laboring surplus population, condemning it to death. In this brutal manner, capital undermines the contribution that growing segments of the laboring population could make to the development of the productive forces of society.

The global unit of capital accumulation realizes itself in the form of independent national processes. This form, itself a manifestation of the private nature of labor, becomes a basis for the fragmentation of the working class according to the differentiation of its role in the development of the productive forces of society.

The global unit of capital accumulation takes place in the form of independent national processes. This form, itself a manifestation of the private nature of labor,

Downloaded by [Baskent Universitesi] at 07:45 23 December 2014

Downloaded by [Baskent Universitesi] at 07:45 23 December 2014

becomes a basis for the fragmentation of the working class according to the differentiation of its role in the development of the productive forces of society.

The classic form of the international division of labor is defined centrally by the supply of raw materials for those countries where accumulation assumes its general form from other countries where natural conditions allow for a higher degree of labor productivity in the production and extraction of these raw materials. Consequently, a mass of differential and simple absolute monopoly ground rent flows towards the latter countries. This mass has its source in the surplus value generated by the workers of the importing countries where primary commodities reach individual consumption. Therefore, this surplus value not only escapes appropriation by the individual capitalists from these countries, but also eludes the national process of capital accumulation itself. Then, these national economies set out to recover for themselves the largest part possible of the rent in question. Historically, they have done so in two ways. Both of these have been in association with the landowners from those countries where the rent is appropriated, and which share it out as a condition for their own emergence and reproduction. The first way in which the surplus value in question returns is through the foreign public indebtedness of the country that benefits from the flow of rent to the country in which it originates. This debt accrues interest rates that are significantly higher than normal rates. The second set-up, which has been in force largely since the 1930's crisis onwards, consists of the countries from which ground rent flows outwards being able to recover it by investing industrial capital in the countries where it ends up. Nevertheless, they do not do so in order to carry out production in these countries on the normal scale required to compete in the world market, but only to operate in the countries on a small scale, which corresponds to their domestic markets. These capitals then balance out the negative effect that their restricted scale has on the generation of surplus value by appropriating part of the ground rent through *ad hoc* state policies. At the same time, the same capitals add to this valorization base, (a) the re-use of machinery that has become obsolete in their countries of origin as the scale required to compete in the world market has evolved; (b) the profits that flow to the capitals in question from the local small capitals through the relationship to be presented below and, more importantly; (c) the purchase of the local labor power below its value. The national segment of the working class is thus doubly deprived of its capacity to take part actively in the global development of the productive forces of society. Such is the content of the national processes of capital accumulation in question, albeit the ideological inversion of this content under the label of 'import- substitution industrialization'.[25]

---

[25] This approach is opposed to the theories of underdevelopment, unequal exchange, dependency and imperialism. The Argentine case is a paradigmatic example of this specific national form of capital accumulation. See Juan Iñigo Carrera, *La formación económica de la sociedad argentina*, Vol. 1 (Buenos Aires: Imago Mundi, 2007), pp. 41–85.

While this form of international division of labor reproduces itself continually, a new form of the same kind of division arises that gives it contemporary specificity. This new form is directly based on the international fragmentation of the productive subjectivity of the laborer in large-scale industry dedicated to production on the world market scale. This fragmentation arises principally from the robotization of the assembly line and the computerized adjustment of machinery. These processes have a two-fold effect on the productive attributes of the laborers. On the one hand, they increase the level of complexity of the labor required to develop control over natural forces and to develop the conscious organization of collective labor; and on the other hand, they simplify to an extreme the manual task of assembly as well as the manual labor, and even the intellectual one, which operate as appendages of machinery. The development of electronic data communications and of transport adds to the counter-movement taken by developments in productive subjectivity.

Through this new development in the international division of labor, global accumulation takes shape through the constitution of a limited number of nations in which capital tends to foster the type of work that expands the productive attributes of the laborer. Capital accumulation determines a second kind of national space as the location for the productive processes that essentially require a labor force whose productive attributes have deteriorated, as it has been determined as a surplus laboring population that is either latent or stagnant. Finally, the global unity of capital accumulation brutally turns other countries into mere repositories for a consolidated surplus laboring population, which it deprives of all productive subjectivity. On the surface, it would appear that the 'globalization' of the production process of industrial capital erases national frontiers. In fact, it rests on the strength that such frontiers have to further cheapen labor power.

In turn, the national differentiation of the laborers' productive attributes is enhanced by the relationship between normal capitals, which prompt the productivity of labor corresponding to the formation of the general rate of profit, and small capitals no longer able to afford to reach that level of productivity. These small capitals have been left behind in the development of labor productive forces. Nevertheless, they continue to produce by balancing their higher production costs against being valorized at the lower profit rate corresponding to the interest rate they would receive if they went into liquidation and they convert this into loan capital. Nevertheless, the sales price set by the compensation arising from higher costs balanced against a lower normal concrete profit rate can fall below the price of production set by the formation of the general profit rate. In this case, the small capitals in question would benefit from an extraordinary profit, well above that corresponding to their normal concrete existence as industrial capitals. However, these capitals cannot avoid competing among themselves for that extraordinary profit, and so it flows away from them in the direction of the normal capitals directly linked to the small ones in circulation. Thus, the former multiply their capacity for accumulation, thanks to the subsistence of small capitals that lack the capacity to

Downloaded by [Baskent Universitesi] at 07:45 23 December 2014

develop society's productive forces.[26] This source of profit for normal capitals accrues greater power as small capitals are particularly suited to exert the ruthless exploitation of the labor force whose productive subjectivity is undergoing deterioration, all the more so when this labor force makes up the greater part of the country's laboring population.

Based on these national differentiations, capital acts against its historical tendency towards the universalization of the conditions in which it reproduces the laborers of large-scale industry. It does so by linking the different productive subjectivities of the specialized organs making up the collective laborer to the different conditions in which each national labor power is reproduced. Hence, the intensified international competition imposed on the national segments of the working class adds to its capacity for exploitation. The issue concerning the kind of unity required by the working class to tackle its double fragmentation by capital—based as much on the differentiation of productive subjectivity as on the international division of labor—is at the root of the issue concerning the forms of consciousness capable of organizing political action.

The Historical *Raison d'Être* of the Capitalist Mode of Production

The development of the productive forces of society through the increased socialization of private labor, that is to say, the reproduction of the capitalist mode of production, takes concrete shape in the negation of this self-same development through the mutilations that it necessarily carries out on the productive subjectivity of the whole of the laboring population. The concrete form in which the capitalist mode of production develops the productive forces of free labor is sufficient proof that this is not the ultimate social form taken by development. It is a specific historical modality that carries within itself the need for its own overcoming.

The transformation of the nature of labor and of the producer of commodities highlights the historical reason for the existence of the capitalist mode of production: the transformation of the productive powers of free individual labor into the productive powers of collective labor consciously organized by the same collective laborer that performs it, under the contradictory form of the development of social labor as private labor. It is about a labor whose product confronts its own producers as the autonomous bearer of the capacity to put in motion the labor of society and, therefore, as the bearer of a social power alien to them that exerts domination on them. This immanent contradiction of the capitalist mode of production is that which makes it bear in itself the need to supersede itself by engendering the general conscious organization of social production through its own development.

---

[26] This modality taken by the normal equalization of the profit rates under the concrete form of their permanent inequality based on the subsistence of small capitals in activity is the true content of that which political economy inverts when it explains the differences in the concrete capacities to accumulate by the market forms. This inversion goes from the Neoclassical theory of 'imperfect competition' to the theory of 'monopoly capital.'

The Centralization of Capital as the Alienated Property of the Working Class

The advance in the socialization of private labor necessarily takes shape through the centralization of capital, that is, the convergence of individual capitals in direct unity as the total capital of society. It is in the context of political action, which is to say, when it directly expresses the powers of social capital, that the working class embodies the direct socialization of private labor. The revolutionary action of the working class is the necessary concrete form in which the aforementioned constant revolution in the materiality of labor—which at the same time entails its direct socialization—develops its need for being organized as a directly social power that transcends the limits of its private capitalist form. Therefore, this revolutionary action is the necessary concrete form in which the capitalist mode of production fulfills its historical need to supersede itself through its own development.

The path is set by the working class taking into its own hands its alienated general social relation, i.e. the working class appropriating social capital. This is a task that can only be undertaken by centralizing capital as state property.[27]

The complete socialization of private labor, that is the absolute centralization of capital as the property of a global state, is the necessary course of the political action of the working class as the highest form of the development of the productive forces of society in the capitalist mode of production. Nevertheless, this is not its real end. Indeed, a process of capital accumulation where the complete fulfillment and control of the labor process were in the hands of the wage laborers and capital was the collective property of these same laborers under the necessary modality of state capital, would be the most developed form of the alienation of human powers as capital's powers. In it, the separation of the laborers from their means of production would be complete, which is to say that the laborers would be directly confronted with these means—that is, without needing to be mediated by the figure of the capitalist—as an objectified autonomous power not only alien to them but also one to which they would be completely subordinate.

The Conscious, therefore Free, Organization of Social Life

The private character of labor, plain and simple, means that the free consciousness that organizes each unit of social labor is deprived of the capacity to control its own social scope. This scope confronts it in an inverted form as the social power that its product—capital—imposes upon it to embody the general unity of social labor. Insofar as free consciousness necessarily personifies the social power belonging to its product, it is determined as an alienated consciousness.

In its complete development, the free consciousness bearer of alienation directly takes form in the materiality itself of the labor process. At this point, work materially consists of applying a scientific consciousness—that is, one that is objectively aware of its own determinations and, as such, one that advances asserting its freedom—to develop control on the natural forces in order to objectify them in machinery, namely, to multiply the capacity to organize the process of social metabolism. Nevertheless, that same product, i.e. the multiplied capacity for organization, confronts its producers under the specific social form of surplus value. That is, it confronts its producers as an alien social power that belongs to the material product of their labor and to which their objective consciousness itself is submitted. It is about an automatic organization of social life in which human labor consists of the development of the capacity to consciously control that very organization, simultaneously having as its immediate object the multiplication of the capacity to automatically organize social life beyond the consciousness of its producers.

---

[27] Karl Marx and Frederick Engels, *The Communist Manifesto* (London: Penguin, 2002), p. 243.

The absolute limit to the capitalist development of the productive forces of society lies in this negation of the complete domination of the very powers of social labor. Therefore, the ultimate capitalist barrier to the development of productive forces lies in the mutilation imposed on free consciousness by its determination as the form of existence of alienated consciousness. The overcoming of this barrier necessarily entails the annihilation of private labor as the way of organizing social labor, thus giving birth to the general conscious organization of the latter.

This step forward in the development of productive forces thus takes a specific material concrete form. Namely, it takes the form of a social revolution in which the material subject of this development, i.e. the working class, does not limit itself to the annihilation of the bourgeoisie by transforming capital into an immediately social property. It annihilates capitalism itself, and, by doing so, annihilates the general political representative of capital, that is, the state. And by anihilating capitalism, the working class reaches its own end. The new general social relation takes shape in the consciousness and will by means of which the laborer directly determines him/herself as an individual organ of social labor. Freedom is no longer about not being subject to the personal domination by another at the expense of submitting to domination by the social powers that belong to the product of one's own labor. Now, freedom consists of not submitting to the personal domination of another because one holds complete sway over the social powers of one's own labor. It has developed as the complete objective consciousness concerning one's own individuality as the bearer of productive social powers. Therefore, it is about the general conscious organization of the process of producing social life. Free consciousness, i.e. free individuality, has become the general social relation.[28]

The historically specific revolutionary powers of the working class to overcome the capitalist mode of production do not arise from the realization of 'right', 'justice', or 'equality' as opposed to capitalist 'unnatural' injustice and exploitation;[29] nor from the realization of the 'dialectic of the moral life';[30] nor from the 'increase of an

internal self-determination or self-morality';[31] nor from the fact that the mere antagonistic relationship that exists between the exploiters and the exploited in class struggle engenders an abstract accumulation of experience;[32] nor from the 'autonomy' achieved by class struggle with respect to its determination as the necessary concrete form of the socialization of private labor;[33] nor from the 'autonomy achieved by the working class' consciousness with respect to capital, be this—in relative terms—by means of the production of a revolutionary 'doctrine',[34] or by means of its 'self-valorization';[35] nor from the 'democratization' of capitalism through the apparent standoff between an abstractly free consciousness and an abstractly alienated consciousness by means of 'market socialism';[36] nor from the production of a working class consciousness able to develop itself by itself beyond the exhaustion of the development of productive forces;[37] nor from the need to avoid 'barbarism' or 'catastrophe' vis-à-vis the mechanical impossibility of capital reproduction;[38] nor from this mechanical impossibility itself;[39] nor from the resistance of the laboring surplus population in its desperate struggle to survive.

Each of these reasons presupposes that working-class consciousness imposes itself—on its own account—upon the actual determination of the social being of the working class as an attribute of capital. Therefore, they are all idealistic inversions to which the materialistic point of view must be opposed. The capitalist mode of production is nothing but the form in which society develops its material productive forces by means of the accelerated socialization of free labor (i.e. by means of the generation and advance of the conscious organization of social labor performed by the direct producers themselves) by aiming for the multiplication of that socialization as the immediate object of social production and consumption. Therefore, this form of the organization of social production takes action directly aimed at reproducing the same mode of organization in a qualitatively and quantitatively expanded scale. Hence, its specific need to revolutionize the very materiality of the labor process, transforming it in the exercise of human faculties to submit natural forces to their conscious control exerted as a direct social power. Yet, for that reason too, the direct producers are presented with the product of their own social labor as an alien power that dominates them; that is, as the very denial of their conscious organization of social labor, which is to say, as capital. Therefore, the capitalist mode of production constantly revolutionizes the materiality of the labor process in a way that entails the necessary overcoming of its own reproduction. Only because it is completely determined as an attribute of its own alienated material product, and as it cognizes itself completely in this determination as the necessary form of the advance in the conscious socialization of labor, the revolutionary action of the working class is today the complete expression of liberating action.[40]

The Consciousness of the Working Class as the Negation of the Negation of Free Consciousness

The need inherent within the capitalist mode of production to develop itself towards its own overcoming into the general conscious organization of social production immediately presents us with the process of the development of consciousness. A consciousness able to organize the totality of the process of social production must have attained the power inherent in the fullness of objective knowledge, that is, it needs to be a completely free consciousness. Nevertheless, it cannot reach this condition as an offspring of the previous overcoming of the capitalist mode of production. On the contrary, this overcoming is the offspring of the complete development of free consciousness. Therefore, complete free consciousness must necessarily be the most genuine product of the capitalist mode of production itself. More concretely yet, it must needs be the product of the social subject that the capitalist mode of production objectively determines as the bearer of its own overcoming, resulting from the same process in which the subject undertakes this overcoming. In a nutshell, the consciousness in question can only be developed as the product of the political action of the working class in the process of overcoming the capitalist mode of production. This action takes, as its necessary concrete form, the advance in the socialization of private labor by means of the centralization of capital as an alienated social property, which is to say, as the property of the state. The consciousness of the working class able to overcome the capitalist mode of production can only be developed as a concrete necessary moment of the aforementioned process of capital centralization.

Yet, the consciousness of the working class is determined as an attribute of capital and, therefore, as a form of alienated consciousness. Above all, the free consciousness of the working class is the necessary concrete form of its alienated consciousness. Hence, it is the negation of free consciousness under the appearance of being a free consciousness. Therefore, the consciousness that bears the overcoming of the capitalist mode of production cannot be developed as the abstract affirmation of

the free consciousness of the working class. It can only be developed as the free consciousness of the working class that determines itself as an alienated consciousness advancing in the denial of its own alienation. That is, as a consciousness whose freedom resides in determining itself as the negation of the negation of free consciousness.

The production of the scientific consciousness of the working class concerning its own historical potential is not an abstract scientific matter. It is a specific moment necessary to the political action of the working class in the class struggle.

Capital's needs concerning scientific cognition face a contradiction. To increase relative surplus value by means of the system of machinery, capital is compelled to submit all production and consumption to science. Nevertheless, insofar as scientific cognition is simply a concrete form of the production of surplus value, science must reproduce the alienation of human consciousness in capital. At the same time, it has to be an objective consciousness, it needs to be a consciousness that looks upon itself in a non-objective way by accepting the appearance of being an abstractly free consciousness. For this reason, it is about a science that needs to appear as if the foundations of its objectivity were rooted outside itself. These foundations must appear to arise from a pure abstractly free subjectivity, as if they were based on a philosophy,[41] grounded in turn on the appearance of free individuality inherent in the circulation of commodities.[42]

Logical representation is this contradiction solved. It starts by basing its objectivity on the conception of real concrete forms as if they were empty of any necessity to be realized and, therefore, as unable to affirm themselves through their own negation. Thus conceived as lacking any potentiality to get into motion by themselves, and consequently expelled from science even the very question about the possibility of apprehending in thought their necessity by ideally following it in its real development, thought can only place them into relation by imposing an external constructive necessity upon them; that is, logic: 'Logic—mind's *coin of the realm*, the speculative or *mental value* of man and nature—its essence which has grown totally indifferent to all real determinateness and hence unreal—is *alienated thinking*, and therefore thinking which abstracts from nature and from real man: *abstract* thinking.'[43]

Thus, logical representation is able to conceive free consciousness as the abstract opposite of alienated consciousness. Moreover, it could even conceive consciousness as the externally contradictory unit between free consciousness and alienated consciousness, these being two opposite poles. But it excludes from the field of scientific knowledge any possibility of discovering free consciousness as the necessary concrete form of alienated consciousness, since such relation violates any logical consistency.

[42] Karl Popper, 'The Logic of the Social Siences', in T. Adorno, H. Albert, R. Dahrendorf, J. Habermas, H. Pilot and K. Popper, *The Positivist Dispute in German Sociology* (London: Heinemann, 1976), p. 96.

[43] Karl Marx, 'Economic and Philosophic Manuscripts 1844' in *Marx/Engels Collected Works*, Volume 3 (London: Lawrence and Wishart, 1975), p. 330.

Given the external character of the constructive necessity followed to conceive in thought the real concrete forms with respect to their proper one, logical representation itself arrives at the logically unavoidable conclusion that it cannot produce the certainty of an objective knowledge before acting.[44] Therefore, scientific theories based on logical representation are recognized by their own producers as necessarily stopping at appearances and, therefore, as being unable to go beyond interpreting reality in different ways.[45] They are but ideologies based on each one's philosophy. In logical representation, ideology manifests itself in the form of its opposite, namely, scientific method.

Marx opposes the 'reproduction of the concrete by way of thought'[46] to logical representation. Reproducing the concrete by way of thought implies that the course taken by the progression of ideas must follow the development of the necessity inherent in the actuality of the real concrete upon which action is going to be performed. Therefore, the movement of thought cannot introduce any necessity alien to its real object, nor force a conceptual point of departure. It can only start by accounting for the necessity of the simplest form presented by its object. That is, dialectics on its feet. Science, namely, the production of the objective consciousness, is thus carried out in a concrete form that immediately corresponds to its content. Therefore, when it is developed by the alienated subject, it unavoidably faces this subject with the evidence of his/her own alienation, whichever the appearance of abstract free subjectivity he/she has started from.

Since it begins, unavoidably, by discovering its own historical condition as an alienated consciousness, this consciousness can only be a product of capital inasmuch as the latter needs to annihilate itself through the conscious general organization of the social metabolism. Therefore, dialectical cognition as practical criticism can only arise as the immediate expression of the general interests of the working class; namely, as the expression of the latter's power to abolish itself as a class by constituting the society of freely associated individuals. Only inasmuch as it expresses this necessity is dialectical cognition able to advance upon the immediate concrete forms of the political organization of privately-performed social labor and of the transformation of natural forces into human instruments. Nevertheless, when it does so, it brings to these fields the revolutionary powers it obtains from its very historical reason of existence.

As long as it remains the prisoner of the self-same scientific method that operates as the objective consciousness capable of producing relative surplus value while seeing itself in a non-objective light, namely, of logical representation, the scientific consciousness of the working class is unable to discover that, in the capitalist mode

[46] Karl Marx, *Grundrisse: Foundations of the Critique of Political Economy*, op. cit., p. 101.

of production, freedom is but the concrete form of alienation. Therefore, it weakens itself within its own historical powers, for it sees itself as an abstractly-free consciousness. Nevertheless, as the very process of capital accumulation imposes the development of direct control over the social character of labor, it follows that the conscious action of the working class needs to move towards overcoming this appearance. It needs to leave behind the exteriority of logical representation in order to rule itself by means of the reproduction of the concrete in thought, that is, by means of dialectical cognition. Marx's *Capital* is, in itself, the development (carried out for the first time and given a form that allows its social reproduction) of the alienated consciousness of the working class that produces itself as an alienated consciousness aware of its own alienation and of the historical powers it derives from it. In *Capital*, this consciousness unfurls to the point where it reaches the general determinations that relate to the revolutionary action of the working class in which the aforementioned historical powers are fulfilled inasmuch as they produce the material conditions for the conscious, and thus free, organization of social life.

Capital's Development into Conscious Revolutionary Action
Critique of Scientific Theory [*]

Juan Iñigo Carrera

The construction of the community of the freely, i.e., consciously, associated individuals is the most genuine critique of the present social organization. Does critical scientific theory, the scientific theory that sees itself as the direct expression of free consciousness vis à vis the general alienation of consciousness in capitalism, appear today living up to this social necessity?

Since that construction can only take shape in the development by each individual of the complete cognition of his/her own real necessity, it annihilates by itself any utopia. Likewise, it annihilates by itself the alienated forms in which the autonomous regulation of the process of social metabolism through the production of value takes shape. It thus annihilates the apparent individual independence as the form of the general social interdependency, to begin with; and, therefore, it is about the annihilation of moral and justice. Still, if the redemption of utopias and the conceiving of moral and justice as the foundations of the necessity of social transformation have a champion today, critical scientific theory is it. At the same time, critical scientific theory has not ceased to externally relate the general regulation of the process of social metabolism - i. e., the general social relation - with the concrete forms through which this regulation realizes itself. Only on this basis, it can go on uncritically representing the social regulation that takes shape in the national accumulation process of the capital that is a wholly collective property within this national ambit (and therefore, as much capital for the whole of the working class, and as much private capital, for the working class of the rest of the national ambits, as any other) as the realized supersession of capital, i.e., realized socialism or communism. Or, seen the other way round, only on this basis, critical theory can go on representing the brutal forms of the alienation of human potencies as capital's potencies in which this process takes shape, as abstract deviations, treason, bureaucratization, external constraints, lack of democracy, authoritarian vices, etc., of socialism in its realization.

Still, what other answers can we expect from critical scientific theory to the renewed demand for a conscious revolutionary action? Let us consider one that is particularly eloquent: 'Philosophers neither interpret nor change the world; science, whose cognitive autonomy philosophy is charged with protecting, does the former in order that the latter may one day be possible.' This is the way in which 'it is now ... necessary to emend' Marx's 11th thesis on Feuerbach, according to M. Sprinker[1]. Most, not to say all, Marxists will certainly agree that this 'emendation' is an attempt to emphasize the critical aim of the statement with which Marx gave way to his scientific discovery of the specificity of present-day society. Some Marxists will certainly object the appeal to philosophy or the frailty of the 'may one day be possible.' Yet, at worst, they will take Sprinker's emendation just as an unhappy attempt to rephrase Marx's thesis; never as an attempt to alter its core. For, Marxism unanimously assumes as being self-evident that the problem with philosophers is not that they interpret the world, but that they do not take action once they have achieved this interpretation. Moreover, Marxism has always postulated that the point is to scientifically interpret the world to face immediately after, on the basis of this interpretation, its conscious transformation. Still, is it the point? What change are we talking about?

---

[*] This is a synopsis of the book I am working on. See Appendix for its scheme. Its first chapter, *Dialectical cognition; i.e., the regulation of action under the form of reproduction of self-necessity by thought*, has been published by the *Centro para la Investigación como Crítica Práctica* (*Center for Research as Practical Criticism*).

[1] Sprinker, Michael 'The Royal Road: Marxism and the Philosophy of Science', *New Left Review*, 191, January/February, 1992.

Green is the tree of life

Above all, life is a process of metabolism, the process where a subject appropriates its environment to produce itself. As such, the living subject carries in itself the capacity for regulating its process of metabolism. That is to say, it is able to cognize the potentiality of its own action and of its environment, so as to control the self-consumption it must undergo in the process of producing itself. Undoubtedly, a long way runs from the capacity for, and form of, regulating itself inherent in a DNA molecule to those inherent in the most developed animal species. Nevertheless, all of these living forms center their capacity for transforming their environment from alien to a medium for themselves and, specially, their capacity for advancing in this transformation, in their capacity for transforming themselves, in their capacity for mutating their own bodies adapting them to the environment. By developing its capacity for transforming the environment into a medium for itself, not mainly by mutating its own body to adapt it to the environment, but by transforming the environment itself, a specific animal form turns itself into the generic human being. In other words, to be generically human imports the capacity for producing one’s own means of living and, consequently, the capacity for producing the means of production of these means of living. The cognition of one’s own potentiality with respect to the medium’s potentiality, i.e., the regulation of the human process of metabolism, extends in a generically correspondent way the degree of foresight it needs to reach.

Human life is a process of social metabolism. Still, this process has no way of realizing itself other than in the process of metabolism of human individuals. Since it is a process of social metabolism that has the individual process of metabolism as the necessary form of realizing itself, the regulation of the former process is the organic unit of the latter ones. In other words, the regulation of the process of social metabolism realizes itself as the social relation among its members; it is the social tissue, so to speak. Since it is itself a concrete form of that collective process, this regulation is necessarily shaped in the action of each of its members. As it happens with any regulation of this kind, the regulation of this process takes shape, above all, in the cognition by each individual of the point reached by the unfolding of his/her process of metabolism and of the corresponding processes of the other individuals that interact with him/her. This cognition is thus the way in which each individual integrates the flowing of the corresponding portions of her/his individual process of metabolism with those of the rest. Naturally, the process of cognition is developed by each individual as a moment of his/her own process of individual metabolism.

The regulation of the human process of social metabolism, the general social relation among human beings, has the purely animal immediate cognition as its historical starting point. At least according to its length, the greatest part of human history up to today is the history of the transformation of this animal relation into the regulation by means of the cognition of the point reached by each individual process of metabolism through direct personal relations. Obviously, human cognition by means of ideas develops along this transformation as rudimentary forms as rudimentary is the complexity of the process of social metabolism that it regulates and, hence, which produces it.

Still, however much human cognition by means of thought might have been developed and however little somebody might know concerning the historical specificity that determines the current form of the human process of social metabolism, nobody would claim cognition is the general regulator of this process today. In other words, it is obvious that our general social relation - the allocation of society's total labor-power among its different concrete forms and the coordination of the individual process of metabolism - does not take shape through the process of cognition of the social necessities.

The absence of a general coordination through cognition in the allocation and development of social labor determines individuals as private independent producers. Insofar as purely such, they have no way to get into relation by themselves to incarnate the process of social metabolism. To begin with, these producers do not retain any general social relation other than that of being individual personifications of society's total capacity for performing productive labor. This total labor-power is, as such, the capacity for performing human labor in general. The realization of this capacity under the mass of its different concrete forms is, thus, the development of the general social relation among the private independent producers.

The human process of social metabolism goes into motion by itself. It does so carrying the cooperation among its members beyond their capacity for - mutually recognizing each other in the development of their respective individual process of metabolism - directly coordinating these processes as moments of the process of social metabolism. The process in question determines itself as the autonomously regulated human process of social metabolism; that is to say, the process in which society allocates its total labor-power among the different concrete modalities of labor by representing the socially necessary abstract labor embodied in the products of the concrete labors carried out by the independent private producers, as the capacity of these products for relating among themselves in exchange. The general social relation that rules the process of metabolism that is able to produce its own medium takes the form of *commodities*; and the socially necessary abstract labor in that way represented, becomes *the value* of commodities. In commodity production, material production produces, at the same time, the general social relation. The private producers lack any direct general social relationship among themselves. They must act, and consequently see themselves, as being mutually independent. They come to face their general social interdependency only through the mediation of their material products. Therefore, this relation appears to them as an attribute inherent in the material form itself of these products, as a fetishistic social relation.

Commodities develop themselves insofar as the concrete unit of their natural form, use-value, and their specific social form, their value-form. In this development, the exchangeability of commodities negates itself as simply such, to affirm itself as the direct exchangeability only of the commodity that all of them detach as their general equivalent, money. From here on, commodity production realizes its necessity by taking the production of this general representative of value, the production of the general social relation in its substantive manifestation, as its general object.

Social production as a production of value transcends itself, realizing its necessity by producing more value by means of value itself, by transforming money into capital. As an accumulation of means of production and means of subsistence for the laborers that opens its productive metamorphosis, capital submits living labor to its necessity of valorizing itself. This is no longer a production of use values regulated by the condition of these as values. It is not even a production of use values which is only a means for the production of substantive value. This is a production of value in itself that yields as its result the production of use values and, hence, of human beings. This happens to the extent of determining as productive, no longer the labor that transforms the environment into a means for itself, not even the one that produces value, but only the labor that produces surplus-value. Capital, materialized labor and, as such, a means for the human process of social metabolism, has taken possession of the generic potentialities of this process. Capital thus presents itself as the alienated incarnation of the generic human being. The product of social labor, a material product that is at the same time the materialized form of the general social relation, has transformed itself into the concrete social subject. From being a formally fetishistic material form, this product thus faces its own producers as the one which produces them, as a real fetish, so to speak.

Whether they like such an alienation of their generically human potencies or not, the bourgeoisie and the proletariat cannot but personify these potencies which now belong to capital. Capital is itself the one that produces and reproduces human beings giving them the concrete forms of the bourgeoisie and the proletariat, on realizing its necessity as a process of simple valorization by transcending into the reproduction of this process. The simple reproduction of capital develops into the process of capital accumulation. Relative surplus-value affirms itself as the general concrete form of this process. As such, its simple form (the increase of labor's productivity in the spheres that directly or indirectly produce the means of subsistence for the wage-laborers) becomes a double determination to the transcendence of the process of capital accumulation from being simply itself.

Above all, the reproduction of the increment in the productivity of labor takes its general concrete form in the increased concentration of the masses of capital individually put into action. And this concentration clashes against private property of capital; not just with particularly restricted forms of this property, but with it in itself. In turn, the reproduction of the increase in the productivity of labor takes its equally general concrete form in the submission of all aspects of production to science; the reproduction of the simple increase of relative surplus value, in the same submission concerning consumption. From which, capital, our specific social relation, carries in itself the necessity of annihilating its historical concrete base, as well as its historical reason of existence; that is, private property in general, as well as the insufficient development of human capacity for consciously ruling its process of social metabolism. In brief, capital carries in itself the necessity to annihilate itself, as its own potency. Since it is empty of any immediate necessity other than the purely quantitative of increasing its own value, capital cannot find a qualitative limit to its valorization process inside itself. It cannot find this limit even in its own impotence as a concrete form of the human process of social metabolism that emerges from the negation of the potencies of the conscious regulation of this process. Hence, from its very root, capital carries in itself the necessity of acquiring the most brutal forms in the exploitation of human labor to satisfy its insatiable hunger of surplus-value. Still, from here, its specific historical potency to drive itself beyond its own limits also arises.

As capital accumulation advances in the concentration of the scale of individual capital and the scientific organization of production and consumption, it transcends the narrow base of private property, already in what this directly personifies in the bourgeoisie the general organization of that process. Capital thereby deprives the bourgeoisie of its historical *right* to exist. At the same time, it determines the very working class from whose surplus-labor it feeds itself, with the mediation of developing it as a collective laborer, as its own general personification. This personification does no longer enclose in itself limitations to its condition as such. Therefore, it is the most genuine concrete form of the process of capital accumulation. And, as such concrete form, it is the working class who carries in itself the necessity of personifying the annihilation of capital. This annihilation is, in itself, that of social classes. It is the annihilation of the bourgeoisie, straightway; no wonder why the bourgeoisie resists it with tooth and nail. But, in this same annihilation, the working class realizes its own necessity, negating itself absolutely as such, certainly, to affirm its potencies as the human potencies of the freely associated individuals; that is to say, of the concrete subjects of the human process of social metabolism that consciously regulate this process on cognizing, each of them, their own determination as such subjects. It is about the supersession of capitalism in the third main step in the historical development of human society, i.e., realized socialism or communism. However alienated in capital this revolutionary potency may be, or better stated, precisely for being such alienated potency, it shows itself as the working class' own potency. And, as the point is the general organization of the process of capital accumulation, the production of the present general social relation, it shows itself as a potency that has the political revolutionary action of the working class as its general concrete form of realizing itself.

Gray is the theory ...

Since its birth, scientific theory has not ceased to increase its potency to transform reality. We can see it today advancing through a renewed deep revision of itself. Once again, it is multiplying its transforming capacity over real forms that were beyond the scope of human conscious action. Apparently, its development has no limit other than the conscious control over all the processes that concern human life. Therefore, scientific theory apparently is the form that the conscious regulation of the human process of social metabolism necessarily takes. Yet, scientific theory itself has already discovered that it moves in quicksand.

As any scientific theorist can tell us, a scientific theory is, above all, a *representation* of reality in thought, by means of ideas. As such representation, all scientific theories result from a constructive process carried out in thought, following a necessity inherent to this process itself, i.e., a *logic*. Theory takes the chaotic mass of real forms that present themselves to analysis and represents these forms by placing them in the general relation dictated by logic. Beyond this point, the complete agreement among theorists breaks off. Today, most of them consider that representation must follow, given the nature of its object, a *formal* logic. Formal logic (even as fuzzy logic) conceives real determination - i.e., transformation - as an abstract immediate affirmation. Confronting this main-stream conception, critical theorists appeal with no less strength to *dialectical* logic. Dialectical logic represents real movement by the interpenetrating, by the antagonism (simple or over-determined), the relative autonomy, of opposites.

Theorists do not agree either concerning how theories take shape in scientists' minds. For some, a theory results from a careful observational process upon reality. For others, it bursts from the sole scientist's mind. And there are those who consider that a theory can only truly arise in a direct relation with practice.

Regardless of the differences theoreticians may have concerning logic's form or the source of their theoretical production, their initial coincidence is wholly reestablished as soon as they complete their constructive courses. They all start from the conviction that scientific cognition naturally takes form in the formulation of theories. Now, once they are formulated, theories immediately appear to them as what they are: as mental constructions that do not carry in themselves any real necessity other than the necessity imposed by their logical coherence. Thus, theories cannot go beyond being the formulation of hypothesis about the reality that exists in potency. Strictly followed, the method itself of theoretical cognition makes evident by itself the irreducible externality of its product, the ideal representation of real concatenations, with respect to these ones' necessity. This evidence is the evidence of the equally irreducible externality between scientific theoretical cognition and scientific cognition's own generic aim (i.e., the regulation of the real appropriation of the means of human life, the regulation of action, under the form of an ideal appropriation of the necessity of this action).

Theories thus face their *moment of truth*. They must prove their correspondence with reality, if they are true or false. To formulate a theory is in itself to represent a real necessity as *a regularity* (even if this regularity is no other than the absence of regularity). From the viewpoint of scientific theory, the question is to reach the certainty about the presence of the hypothetically postulated regularity in the singular case upon which action is going to be taken. Let us assume that the hypothetically postulated determination has been verified by comparing the foreseen results with the real ones in all the cases of similar appearance taken into consideration. Nevertheless, this fact does not allow one to be logically certain about the unavoidable extension of the regularity to the singular case now faced. Therefore, theories cannot be verified previously to the action based upon them. Scientific theory seeks for the solution to this impasse by turning the problem upside down: although theories cannot be verified, at least their potential falsity can be proved. To do so, it suffices with finding one previous singular case from which the postulated relation has been absent. When this happens, the regularity of that relation with respect to the case now faced can be put into question. Still, this circumstance does not allow one to go any further concerning the original problem. Although one can establish the falsity of a hypothetical relation in each case submitted to proof, nothing logically allows one to be sure that this relation will not arise, from the new case at stake on. Still, above all, although it could free one from mistakenly believing that one knows reality, even the certitude concerning the falsity of a theory would leaves one as lacking that positive cognition as one was.

In addition, the scope of scientific theory does not appear only limited by the relation of its results with reality. Gödel's theorem presents scientific theory as having a limit to its scope in its logic itself. Even in the specific field where the limitations to verification naturally do not come in, mathematics, scientific theory has already shown its frailty. If it tries to build mathematics by coherently following the development of formal logic, it arrives at Russell's insoluble paradox. If it tries to avoid this paradox by axiomatically ruling it away, it cannot even justify such a spurious procedure through its success: it ends up backfired by Skølem's and infinite regression paradoxes. At the same time, modern scientific theory represents the measure of the necessity which actually exists as a possibility that relates with itself in its realization, through chaos theory. In it, reality's nature itself apparently places an absolute limitation to the certainty of scientific cognition.

The theoretical stream that directly flows from modern Positivism accepts these limitations to the scope of scientific theory, that arise from the externality of the logical necessity with respect to the real necessity that is represented, beyond any doubt. It starts with Popper's self-complacent whining about 'rationally discussing' what cannot be 'rationally proved' to have any real content, goes on with Feyerabend's degraded 'everything goes,' and ends up with Rorty's open contentment. Post-Modern theory has its own existence determined by the social necessity to theoretically assert, as an absolute truth, the impotence of any scientific cognition to overcome theoretical incertitude. Yet, what alternatives offers us the scientific theory that sees itself as the genuine criticism of Positivism?

To begin with, we find the critical scientific theory that counts on overcoming the impotence of theory to reach the certainty concerning its truth thanks to the presumed superior self-consistency of its dialectical logic: while formal logic can only represent the results of movement in general, dialectical logic represents this movement in itself. How does critical theory know this? Because it considers the form in which this movement manifests itself once and again as the unity of two opposite elements[2]. Or because it thus acquires a greater range in its 'explanatory power,' in its ability to demonstrate the necessity of the observed phenomena[3]. In the first place, the self-consistency of logic does not add more content of reality to the theoretical hypothesis than that of being the product of a constructive course developed with a greater or lesser self-consistency. In the second place, not even a step has been given here towards the reason of the general real necessity, beyond its appearance of an abstract repetition. Or, even worst, the certainty concerning the content of reality of a theory is declared possible by appealing to an absurd sort of inversion of the proof: the point is no longer to demonstrate the theoretical necessity in reality, but the necessity of reality through logic. In both cases, the necessity of contrasting the result theoretically predicted against reality remains untouched. In fact, all the question has come down to contrasting the representation's most abstract form, its logic, with the concrete real forms. This attempt to overcome the limitations to the reach of scientific theory does nothing but to renew them.

Critical scientific theory steps backwards. It now accepts that verifying its results is only possible as the foresight of main tendencies[4]. Still, it happens that these tendencies have no way of realizing themselves other than in concrete human action. And the action that realizes a tendency can appear as its very negation, inasmuch as the inverse relation may be possible. Let us recall that, 'all science would be superfluous if the form of appearance and the essence of things immediately coincided.'[5] Thus, the nebulous field that goes from the tendencies that are presumably known to the necessity of the concrete action that realizes them, is consecrated as the kingdom of opportunism, by the critical scientific theory itself.

Critical scientific theory seeks for the solution inside the theoretical procedure itself. It tries to solve the question of the certainty concerning the reality of theories through the immanent critique of theoretical developments[6]. Still, to be such, this immanent critique must follow the logical necessity even more rigorously than the criticized development. Therefore, deep as it may go into a theory, this immanent critique has no way of overcoming the externality of the logical necessity with respect to the real necessity.

Critical scientific theory does not know if its own impotency must horrify or fascinate it. In both cases it goes on by considering itself free from the hopeless problem of verification. In the first case, because it has decided that its truth criteria reside in its moral foundations, in the elevated aims that guide it[7]. That is to say, it presents itself necessarily constructed on the basis of a philosophy. We come thus face to face with the ideological negation of scientific cognition, i.e., philosophy, placed as the necessary departing point of the scientific cognition of reality. In the second case, this scientific theory directly declares any question concerning the truth or falsity of a theory to be meaningless. It starts by resolving that scientific cognition only deals with the mental forms through which it represents reality, but not with the real forms themselves. Hence, it declares eliminated by nature the necessity to confront the reality of the theoretical construction. From here on, it believes enough with declaring itself the working class' revolutionary doctrine, to sustain its cognitive superiority[8]. Thus, it can only end up by concluding that all which matters concerning a scientific theory is its usefulness towards promoting action[9]. What does not have to matter in the least to accept this complete emptying of scientific cognition, is that the action thus based can be anything but an action with cognition of cause. We are dealing with an action that sees itself having no other aims than those it abstractly ascribes to itself. Dressed this time as heuristics, ideology takes the place of scientific consciousness regarding the necessity of one's own action.

As a last resort, critical scientific theory vindicates practice itself as the instance that renders the verification of hypotheses possible[10]. Unfortunately, the realization of this verification presupposes the realization of the action. This position implies by itself that there was no way of knowing if the theory was true or false, in the very moment that the action was performed; that is, when cognition really matters. Likewise, this fact uncovers the vacuity of the attempt to overcome the impossibility of verification by alleging that scientific theories are not 'predictive' but 'explicative'[11]. Thus pushed beyond any hope, critical scientific theory tries to conceal this fact attributing the potential of verification, not to each concrete singular practice but, to an abstract social practice. Theory is verified, we are told, in the historical development of the transformation of reality accomplished by society on its basis[12]. Of course, any other ideological representation, e.g. religion, can make the same claim in its favor.

Reached this point, critical theory does not need to give even one further step to consecrate, together with the successors of Positivism and with Post-Modernism, the socially dominant representation as the possible scientific truth; and, hence, that only is scientific that which the referees of scientific community pronounce as such. Stated in 'critical' terms, that the course of certainty about scientific cognition runs through hermeneutically incarnating intersubjectivity, thanks to communicative action. Of the critical intention merely remains the assertion that, just as the restraints to theory apply to natural science, the limitation of social theory to cognize reality insofar as it exists as a potency will asymptotically reach its resolution under socialism[13]. Or, otherwise, it merely remains the assertion that the very necessity of scientific cognition concerning social forms will be extinguished in socialism, on representing the overcoming of alienated consciousness as the possibility of wholly cognizing these forms in an immediate way[14]; as if socialism were not the supersession of the form of social regulation which, in turn, has precisely emerged from the insufficiency of immediate cognition to carry out that regulation. Thus, in both cases, the alleged critique even surpasses the modern successors of positivism when the time comes to elude the questions that today emerge in concrete practice from the non-verifiability of theories, by presenting these questions as matters of pure scholasticism.

In fact, not even the realization of an action solves the problem of the truth or falsity of a theory. The attempt to verify it at this point is not only inopportunely late, but impossible. The concrete real forms - resulting from an action - that fall inside the scope of one's cognition without the mediation of the theory one wants to verify, may completely agree with the theoretically foreseen ones. Nevertheless, this agreement does not tell one anything concerning the correspondence between the real determinations that the concrete forms carry in themselves and the ones theoretically conceived. It suffices with recalling that, since scientific theory represents the generic necessity by regularity, it is impelled to give as the cause of phenomena the very form of them. Which theory concerning any voluntary action can resist falsification better, but that which presents human will as the determinant of this action? And if the "revolutionary or democratic will", the "will to advance or to dominate," etc., are quite haggard lately, it is only because the season of boasting by naming *rational choice* one's shortsightedness - but, rather, *irrational philistinism* - has arrived. Again, the abstract forms do not manifest themselves identically to themselves in their concrete forms.

However we face it, the point is that it is impossible to logically show the truth of scientific theories previously to action. Any action based upon them cognizes its own necessity only through the relations it establishes to represent the real forms. At best, this representation is based upon the discovery of the abstract determinations, by separating that which repeats itself from that which does not. At worst, it directly establishes relations between the abstract determinations according to the author's opinion. Whether we like it or not, scientific theories cannot go further than interpreting reality in different ways. They are ways of interpreting the world. However powerful an action based upon a theory may be to transform reality, it is in itself the negation of the action which thoroughly cognizes its own necessity beyond any appearance, insofar as it is based upon an interpretation. No wonder scientists themselves end up condemning scientific knowledge, as a consequence of its logical method itself, to the field of 'exhausted utopias', of hopeless 'emancipating grand narratives.' This happens to the extent that the belief that it must be taken for granted the ideological determination of all scientific cognition, currently passes for the most unquestionable historically conscious criticism of its present general form.

The historical nature of scientific theory

The contradiction is obvious. Any interpretation of a real determination is in itself the negation of the cognition of that determination that has gone beyond any appearance presented by it; the interpretation of one's own necessity is the negation of its complete cognition. As much as scientific cognition is condemned to interpretation, so is condemned to impossibility the general conscious regulation of social life through the cognition by each of its members of his/her determinations as such overcoming any appearance. In other words, as much as scientific theory is the final form of scientific cognition, so is socialism condemned to impossibility. Even the most blatant apologetic cretinism of capitalism has nothing else to ask for: from the lips of its true representatives, the very same scientific method declares that 'the end of history' has been reached, that 'the future is already here.' If one had Orwell's expressiveness, one could well say that when one looks from the scientist to the ideologist, and from the ideologist to the scientist, it already is impossible to say which is which. *The* *question of the form of scientific cognition confronts us as the question of the necessarily historical nature of scientific theory.*

In the autonomously regulated system of social metabolism, individuals can only realize their social interdependence through their own independent behavior. Therefore, their social interdependence necessarily faces them as being external to their own necessity as abstractly independent individuals. To their own consciousness, abstract individual *will* seems to clash against the limits that the social interdependence externally opposes it. This determination, specifically inherent in a commodity-based society, immediately excludes the complete cognition of one's own necessity as the general form of consciousness in this society. The alienation of human potencies as potencies inherent in the materialized general social relation, commodities, acquires, in this exclusion, the form of an alienated consciousness. This apparent consciousness begins its specifically capitalist development by necessarily representing the extraction of surplus-product from wage labor without compensation, as an exchange of commodities where only equivalents are involved. The discovery of one's own necessity in any field is, by itself, the negation of this alienation in general.

Capital's necessity concerning scientific cognition faces a contradiction. To increase relative surplus-value, capital is compelled to submit all production and consumption to science. Nevertheless, insofar as scientific cognition is a concrete form of capital's simple necessity to valorize itself, science has no way of overcoming the alienation of human consciousness in capital. *Scientific theory is this contradiction solved.* Scientific theory represents real concatenations by taking the forms where the necessity is already realized - concrete forms - as if they were not, at the same time, forms that carry in themselves a necessity to be realized - abstract forms. It thus puts the real forms as being unable to move by themselves. From this point of view, only an external relation fits between them. It is here that *logic* comes in.

Placed as being incapable of moving by themselves, the real forms are represented as forms that affirm themselves through the appearance of being abstract immediate affirmations. This appearance really corresponds to the self-affirming by means of the negation of self-negation- i.e., to the real quantitative determination, abstractly considered. The logic of scientific theory is, by nature, the logic that genuinely belongs to mathematics. Of course, to be used to structure the representation of qualitatively different forms in general, it must be emptied of the specificity it gets from the specificity of its object, i.e., the specificity of the quantitative determination. Consequently, scientific theory represents it as *formal* logic. Based on this logic, it represents the real abstract determinations by the relations of measure of their concrete forms. This representation allows the conscious regulation of action upon real forms: although the real necessity at stake is not truly known, it is possible to act upon the magnitude of the real forms, transforming their quantity until making it correspond to that of a qualitatively different form, thus transforming their quality itself. The limits to the scope of this action become evident as soon as the form of its regulation is shown.

Dialectic materialist logic does nothing but to take the same abstract immediate affirmation as the simplest form of real affirmation. Its only specificity arises from representing each of these affirmations as necessarily being united to another one of its same nature, which appears to be opposed to it. That is to say, the simplest real determination, the self-affirming by means of self-negation, is represented as an external abstract relation between opposites. From which, the formulation of dialectical logic can only get to generically enunciate its specificity. Beyond this point, it has no substance left other than the one of the formal logic it carries in itself. So, when it attempts to face any concrete question it immediately ends up reduced to this logic. Let us consider, for instance, G. Carchedi's development[15], maybe the most elaborated among the many recent ones. Carchedi represents the forms to be determined as being 'contained' as potencies in the determinant ones. It thus appears to transcend the externality of formal logic. Nevertheless, this representation does nothing but to preserve this externality. On its basis, the necessity of facing the fact that the determinant forms are such for being themselves those potencies, is left aside. Next, Carchedi represents determination itself - i.e., the realization by the determinant forms of their necessity as potencies, thus determining themselves as concrete forms - as a 'system' of mutually related already realized forms. The determined forms have no place in this system as the concrete forms in which the determinants realize their necessity and, therefore, as these ones in their concrete existence itself. They only fit in the completely external relation of 'conditions' for the reproduction or supersession of the determinant forms. All the necessity that fits into each of these steps is the necessity of the logical representation of the real determination as an abstract immediate affirmation. To preserve this logical externality, Carchedi needs to reduce the method of inquiry to analysis. Hence, he considers the unfolding of the real necessity in thought as a mere resort for presentation. It is impossible to avoid recalling here with Marx that, 'It is, in fact, much easier to find by analysis the earthly core of religious mistiness than, conversely, from the real relations of life at each moment, to develop their celestial forms. The latter is the only materialistic and, therefore, scientific method.'[16]

Dialectical cognition; i.e., the regulation of action in its form of the reproduction of one's own necessity in thought

The critique of scientific theory has no way of taking shape in the formulation of a new logical paradigm. In other words, the critique of the current universally dominating science does not take shape in the construction of a new theory, but in the supersession of scientific theory itself. Thus, it is not about conceiving a new *representation of reality*, condemned by its sole condition as such representation to follow a constructive necessity alien to the real necessity, to follow a logic.

Which is the point then? Let us face the object of our cognition, reality. Outside the theoretical world, reality does not present itself to our minds as an abstract generality. It presents itself as a mass of concrete forms that we distinguish from each other as simply being such. Therefore, we start lacking any way to mentally appropriate the relation these forms have with ourselves, other than by taking them one by one. Whichever we take, it will face us as a potentiality, as a necessity to be realized (at least, in its temporal determination) when we look at it once isolated. There is nothing to wonder about. If real concrete forms are of any interest for us, let alone a nebulous abstractly contemplative one, it is because, as potencies, they can affect us on realizing themselves and, rather, because we can realize the potencies they are with our action.

To discover the selected concrete form as a potentiality, we have just put into action our capacity for immediate cognition. There was no need of any scientific cognition nor, *a fortiori*, of a theoretical cognition. Of course, we can try to realize the discovered potentiality right away with our action. Still we have no guide for this realization other than what the immediate appearance of that potentiality tells us about itself. And our immediate cognition also tells us that appearances often fool us. The point is to discover the reason, the necessity, of the real potentiality at stake.

---

[15] Carchedi, Guglielmo *Class ...*, *op. cit.*.

[16] Marx, Karl *Das ...*, *op.cit.*, Vol. I.

However we look at it, the real potentiality we are attempting to cognize has nothing to add concerning its necessity, other than facing us with its appearance of being such potentiality. Nevertheless, our immediate cognition is still far from exhausting its capacity. The selected concrete form already appears as a potency to be realized, whose necessity is not reduced to this potency itself. On doing so, it tells us that we can only search for its necessity as a potency in what it has, not of an actual potentiality, but of a simple already realized actuality.

We thus face the selected real form as an actual existence that carries in itself a potentiality to be realized. To search in the real concrete form insofar as it is a simple actual existence, for the necessity of its existence as a pure potency, we must consider the former form of existence separated from the latter. It is about isolating the necessity from its form of manifesting itself. This is the last thing our immediate cognition has to tell us, since we can only accomplish this separation inside our thought. The time to begin with our scientific cognition of the real concrete form we are facing, has arrived.

Let us separate with our thought the necessity of the real concrete form from its form of manifesting itself. In other words, let us analyze the real concrete form. Thus separated, the necessity that was realized as an actual existence faces us as a potency to be realized, as the potentiality of determining the concrete form in which it is already realized. The real form cut out by our immediate perception thus faces us as a concrete form that is such for carrying in itself its own necessity of existence as a pure potency, i.e., its own abstract form. Since it is the necessity of existence of a real form, this abstract form can neither be more nor less real than its concrete one. In their pure reality, they only differ from each other by the modality in which they carry in themselves the same real necessity. The real necessity the abstract one has as the potency that determines it as such, is that which the concrete one has as its correspondingly determinant actual necessity.

Still, as such potentiality to be realized, the discovered abstract form cannot account for its own necessity either. It can only face us with its own necessity as the other-self that it carries in itself. Nothing is left for us, but to penetrate deeper by means of our thought into our starting real form. And we repeat this deepening, as many times as the abstract form consequently discovered shows to enclose inside itself its own necessity of existence as a pure potency. Therefore, our uninterrupted progress through the link thus defined is the only necessity that formally determines the course of our analytical process.

Let us consider a brief example. Since the point is to transform the world, let us take, from the mass of concrete forms that we start by facing, the form itself we are going to give our transforming action. What is to be done? Our transforming action tells us, thus, just by imposing this first step upon us, that it is not simply itself; that it is itself and at the same time a different thing: the very question of *what is to be done*. It makes us know, therefore, that it carries in itself a determination that is not reducible to it itself. And this is all our transforming action can tell us about itself in its immediateness, though we may face it and interrogate it once and again.

To continue forward with the realization of our action as an action whose regulation pertains to us, as a conscious action, there is nothing left for us but to confront the *what is it to be done* itself. In doing so, the *what is to be done* shows in such immediateness, as it itself and at the same time an other, the necessity of our action. After which, the *what is to be done* has nothing to add about itself, not being through what this necessity of our action can tell us regarding itself. Let us face, then, the necessity of our action. This necessity can only point out that our transforming will is the other one that it carries in itself; the other one where its own necessity resides. Now, our transforming will can only tell us, concerning its own necessity, that we must search for it in that which our transforming will has of the working class' own transforming will. When we face the working class' will, it cannot give us immediate reason about itself, either. How could it, without forcing us to account for what it has of a simple class will, first? Nevertheless, the clash against the absence of immediateness with respect to self-necessity repeats itself: classes limit themselves to tell us that we must look for theirs, first of all, in what they carry in themselves of the reproduction of the process of capital accumulation.

Let us stop for a moment at this point in the development of our transforming action. So far, it has materialized itself in the search of the necessity of its concrete forms. As such, it has get to tell us that it carries in itself the transforming will of the working class. But it has equally get to tell us, that the will of the working class is not self-sufficient to account for its own necessity, that this necessity transcends it. With which, our transforming action has told us that, just as the transformation of the world takes in itself the working class' voluntary action, neither the concrete forms -and therefore, the working class' political organization - nor the transforming potency of this action, are simply born from the said will itself.

If we want to go on advancing in the realization of our conscious action there is, thus, no other way left for us now but to confront the reproduction of the process of capital accumulation. But, concerning its own necessity, this reproduction does nothing but to point us back to its content of the valorization process of capital. When we face this, it shows itself, insofar as a simple process of value valorization, enclosing a process of simple value production, a production process of commodities. And this process points again back to its material nature, to its content as a process of human life. To account for the necessity of this process, where the exchange between human beings and nature presents itself as a process of work, we need to look back into its necessity as a simple process of metabolism between a living being and its environment. The analysis of purely social forms has turned, in its own development, into the analysis of pure natural forms. Yet, the form of our analysis has not changed at all. We can only go on advancing it by questioning the, now natural, form we come to face for its own necessity, i.e., for the real abstract form it carries in itself as the one that determines it.

Since we are going on advancing over increasingly abstract forms of the determination, the time will come when we are not going to face necessity as the potentiality of this or that determined form any longer, but as the potentiality of determination itself: as much as our object is a determined concrete real form, determination itself is its abstract real form as much as any other. But it is not an ordinary abstract real form. As the rest, it starts by facing us as a concrete form. Still, insofar as such concrete form, it is a pure potential necessity, the necessity itself of being determined and, consequently, an abstract form. Its potential necessity is no longer an-other of its concrete form, but such potentiality is what this real abstract form is insofar as a concrete form. This simple real form has the necessity of its own existence as an immediate actual necessity, it is existence in itself. Still, as far as this actual existence the simple form has is the necessity of transcending from itself into realized determination, the simple form is, at the same time, potential existence. As such, simple existence, *matter*, is a contradiction in itself. Then, it has no way of affirming itself other than by realizing its potency as a determination to be realized, that is, by negating itself as such potency to affirm itself as a realized determination.

We are thus facing the simplest moment in which the necessity of the concrete real form we have originally selected and, consequently, of our action, unfolds itself. Now, since it becomes the affirming of the simple form by means of its negation as such, the realized determination is the real reproduction of the necessity of self-affirming by means of self-negation. And as such it unfolds in the development of the progressively more concrete forms of our real object. Each of these concrete forms (which is such for actually existing as a realized necessity) is, precisely for that reason, an abstract form (which is such for actually existing as a necessity to be realized, as a potency). Thus, determination develops into the transformation of an existing form, on negating itself in its actuality insofar as an abstract one by affirming itself as a realized necessity, a new concrete form, whose actual existence is that of being its self-negation as such concrete form, by self-affirming as a necessity to be realized. When a form simply affirms itself by means of its own negation, its necessity reaches its term, acquiring a more developed shape both as an already realized and as an actual potency. The form determined by the original necessity thus transcends its quality, realizes its *qualitative* determination. The necessity that determines the new form as a potency has emerged purely and exclusively from the primitive one; hence, the new necessity is nothing but the realized form of the primitive one and therefore, it itself. However, as the negation of the negation, this potency is nonexistent for that primitive form in its abstract condition as such: it is just a potency inherent in its concrete forms. Do we have a better way to thoroughly cognize the qualitative potential of any given form, other than by reproducing with our thought the real necessity that has come to such form in its development, by ideally following this development?

At first, an abstract form exhausts its potency on becoming its corresponding concrete form. Still, as any other, the very form of realizing necessity undergoes its own development. Now, the abstract form is in itself not one but many different necessities to be realized. Moreover, these are potencies whose realized forms mutually exclude themselves as the same concrete form, potencies that exist together with their contraries. Such potencies do not have their actual existence in the abstract form as a simple power to be, but as a power to be that is, at the same time, a power not to be: as *possibility* or *contingency*. The abstract form exhausts its necessity only on becoming a diversity of concrete forms, each of them solving the mutual compatibility of those potencies as realized ones. Abstract forms thus determine themselves as *genus*; their concrete forms, as differentiated *species* in which the genus realizes its necessity.

Since it is a concrete form taken by determination, possibility itself develops into a necessity actually existing as a possible potency, that has the necessity of the very course of its realization determined as a possible potency. The determination of the species by the genus thus develops through the mediation of possibility as a specific form the realization of possibility itself takes.

As an already realized possibility, a species is completely impotent concerning the determination of its own possibility. From its viewpoint, the realization of necessity - *causality* - takes the form of *casualness*, of *accidentalness*, of the necessity that, at the same time, is no necessity whatsoever. Each species thus appears as the absolute materialization of the generic potencies that have directly determined it; and these potencies, as its circumstances or conditions. *Life* is the overcoming of species' impotence concerning their own determination as concrete modalities through which possibility is realized: it is the concrete form that has the potency for appropriating its own conditions and transforms them into concrete existences, thus determining itself as an abstract form. Life advances in its real potency by appropriating its conditions in their very virtuality. Life is thus determined as the transforming action that regulates itself through the *cognition* of its own necessity. Seen from the outside, just because it is completely determined as a necessary concrete form of matter, human action can transform other forms of matter into forms for itself; and, therefore, can transform itself. And only because it finds itself thus determined, human action necessarily becomes, in the historical process, a *free* action: an action that integrally cognizes its own necessity.

As it is obvious, in a previous stage of the exposition we have unfolded what remains of our return to the increasingly concrete forms of the necessity of our conscious transforming action by reproducing it through the path of thought. This, and no other, is the necessity that makes the "tree of life green." At a certain point of that unfolding, we have left behind the field of pure natural forms. Thus, we have entered the specific field of the real forms in which a particular process of natural metabolism, that has ceased to be a specific form of animal existence to acquire a generic being (the capacity to produce its own means of living through work), organizes itself. That is, we have entered into the field of social forms. Yet, there was no way to go on advancing in our cognition other than by proceeding in the same way we were doing while we were dealing with simple natural forms. That is, by following in our thought the realization of the necessity that existed as a potency in the real abstract form we had reached already, through which this one transforms itself into a concrete one.

When we are going to ideally appropriate the necessity of our action, we face the object of this action as what it is for us in that moment: something external. We therefore face our object by its immediate exteriority. We overcome the appearance of this immediate exteriority upon advancing through the abstract forms of our object. The analysis inherent in scientific theory separates the abstract forms according to their degree of repetition. It thus stops at their exteriority. On the contrary, the analysis that is going to support the reproduction of the real necessity in thought separates the concrete form that we face, from the necessity that it carries in itself as the other-one whose realization determines it. That is, it takes shape in the discovering, inside the concrete form (and as such, realized necessity), of its abstract form (and as such, necessity to be realized). Given its form itself, this analysis cannot stop until it reaches the real form that does not carry in itself another one from which its necessity arises, but which is, by itself and not by another-self, necessity of negating itself as abstract existence to affirm itself as concrete existence. That is, until we face matter as simply such.

The return towards the concrete forms that comes after the analysis that has stopped in the externality of the abstract forms, unavoidably takes shape in the addition of the non-repeating, and consequently previously excluded forms, to the representation. This process has no other necessity to follow than the purely constructive one dictated by its logic. Hence, the inevitable externality of its result with regard to the real necessity that the action aims at realizing. On the contrary, the reproduction of reality in thought advances by following the development of the necessity that the simplest abstract form carries in itself. As soon as this abstract form realizes its necessity, i.e., it affirms itself as an abstract form, it negates itself as such abstract form to affirm itself as a realized necessity, i.e., as a concrete form. But this concrete form immediately negates itself as such, affirming itself as a form that carries in itself a necessity to be realized, i.e., as a new abstract form. We ideally follow, thus, our real object in its own development. This reproduction of the development of the real necessity by means of thought is unable to get to its end before reaching a form whose necessity exists only as a potency, and this potency has our transforming action - determined as an action that has needed to follow all this path to become a conscious action - as its necessary form of realizing itself. That is, it is unable to get to its end until our action can discover its own concrete form of conscious action, i.e., can discover itself, as the necessary concrete form of the realization of the real potencies at stake. Due to this form of its method, the ideal reproduction of reality is determined as *dialectical cognition*.

In brief, the point is *to virtually appropriate reality by reproducing its necessity through thought*, the *ideal reproduction of reality*. Hence, the development of scientific cognition as the regulation of the transformation of our present society into the one of the freely associated individuals is the *critique of scientific theory*.

Scientific theories arrive at the formulation of certain general laws, but anyone that has to deal with everyday practical matters knows that there is an abyss between these two. The justifications of the link between *the theoretical model*, *the theoretical framework* and *the concrete practice* cannot but resemble what Marx referred to as the dialectics of 'on the one hand ... , on the other hand ... .' Given the way it proceeds, the ideal reproduction of reality needs to integrally unfold itself upon facing each singular action that is going to be realized. Each singular unfolding carries in itself the production of the general unfolding of dialectical cognition. Nevertheless, the existence of this general unfolding does not allow us any abridgment in the necessary singularity of the renewal of our dialectical cognition. The attempt to immediately relate the general necessity with the singular necessity at stake, can only take shape through the introduction of an external link between them, thus mutilating the twofold process that produces the ideal reproduction of the latter necessity. The existence of the general unfolding only allows us to unfold our cognition process in each singular occasion with the agility of being not just a process of purely original cognition, but a process of recognition in the corresponding part. Due to its very form, dialectical cognition submits to criticism the portion of itself developed up to that moment, in the concrete singularity of each of its renewals. It makes this portion account for its condition as an ideal reproduction of reality faced with the movement of the subject that concerns it. By the way, we can see that abstractly, and therefore externally considered in themselves, all that dialectical cognition gets from the practice based upon it, is a new real more developed concrete that it needs to face in the thus renewed satisfaction of its aims.

The ideal reproduction of reality is a product of the double process of analysis and synthesis, in its indissoluble unity. Nevertheless, it is only in its second phase that this process actually follows the unfolding of the real necessity of the object under consideration and, therefore, where its ideal reproduction in a strict sense, takes place. The exposition of this reproduction is consequently determined. Dialectical research cannot overlook any form pertinent to the development of the necessity of the concrete object that is going to be personified. The critical reading of the exposition of dialectical research unavoidably carries in itself the development of the research process itself by the reader, with the potency that this process acquires as it advances supported by the original research. The nature of this unity between the dialectical cognition already produced and its critical reading results in the independence of the exposition with respect to the necessity of strictly presenting each and all the ties discovered by research in the development of abstract forms into their concrete necessary forms. According to its specific aim, the exposition can thus be limited to fully unfold only the discovered ties that are essential for enhancing the critical reproduction of the research.

When we face the magnitude that the necessity of our action has, to cognize it as such, we have to deal with a real form in which the general self-affirming by means of self negation has developed into its specific form of self-affirming by means of the negation of self-negation. In other words, we have to deal with a real form in which the general necessity to become has acquired the specific form of the difference determined as indifference. Hence, we have relations to discover, but we cannot discover them by following their development with our thought. We can only discover the quantitative relations in a completely external way with respect to the unfolding of their own necessity as the abstract real forms they are.

Lacking a real necessity whose development it can ideally follow, our cognition process has to provide itself the necessity of its course; that is, a strictly constructive necessity. Inasmuch as we unfold the ideal *reproduction* of reality as a process of measuring, as mathematical cognition, it necessarily takes the form of an ideal *representation* of reality. Nevertheless, the nature itself of the object of this representation, where the content appears in its form by means of the negation of its own negation, overcomes any restriction to the validity of the logically represented relations. This happens to the extent that the process of recognition of an original demonstration may be accomplished by simply reproducing this demonstration, but also as the mere application of a previously demonstrated formula, that is., just by showing the relation as demonstrated.

Freed from the inversion due to its use as a representation of qualitative determination in general, logic directly reflects the specific quality of its object, quantitative determination. The logical relations do not appear now as representing attributes inherent to abstractly mental forms, to the truth or falsity of one's logical thoughts. These relations immediately show themselves as what they are: representations of the concrete forms of the real quantitative determination. The need to empty logic of the specificity of its object, forces the representation of *the number* by *the set* in the mathematics produced by scientific theory. Nevertheless, the set is the unity of continuity and discontinuity represented under its concrete form of the term of the unity between intensiveness and extensiveness. The development of the representation of the concrete forms that mediate between this unity and the true concrete form that is represented by the number, i.e., the identity of the unit and the multiplicity where the exteriority of the quantitative determination appears completely unfolded, is consequently inverted. It does not appear under its proper shape of a simple logical development, but as a representation of the magnitude of an abstract form by the relations of measure of its concrete forms, as *mathematical analysis*. Thus proceeds the universally dominant mathematics today. It starts with the representation of the number as a set (G. Frege), follows with the relations between *transfinite magnitudes* (G. Cantor), and ends up by representing the realization of the relation of the unit with itself in the degree of multiplicity as the *limit* of the change of the ratio between variables (K. Weierstrass). Hence, the development of dialectical cognition carries in itself the necessity to revolutionize scientific cognition even in the part in which this cognition keeps representation as its necessary form.

The apparent separation between cognition and practice stems from the nature of the historical stage of humanity's development in which the regulation of the process of social metabolism by means of thought - the specifically human regulation of the process of social metabolism - is alienated, turning itself into a concrete form of the autonomous regulation of this process by the production of value. Only in this historical stage can scientific cognition appear denying its true immediate condition as the necessary form taken by the regulation of conscious action. Moreover, scientific cognition can even appear as the very denying of action, as its abstract opposite, in other words, as theoretical cognition. In the very form of its method, that is, as *dialectical cognition*, the reproduction of one's own necessity by means of one's thought immediately shows itself excluding all appearance of externality in relation to the action that it sustains. It shows itself, therefore, as what it is: the regulation of such action, that is to say, a specific portion of this action and, consequently, this action itself. Scientific research thus overcomes all appearance of being the abstract opposite of practice, to affirm itself as *practical criticism*.

As a concrete form of social relations, the conscious regulation of the process of social metabolism under the form of the ideal reproduction of reality - dialectical cognition- is necessarily a task of the collective laborer cut off by the execution of the transformation of its environment on the basis of this regulation itself. This collective laborer only affirms itself in its unity as such with respect to the process of the virtual appropriation of reality, in the development by each of its members of, at least, the whole reproduction of the necessity of the portion of the collective action that, as such member, it is for him/her to perform. Consequently, inside this collective laborer there is room for the differentiation between the partial moments in which the regulation and the, in a restricted sense, realization of the action are unfolded. Still, the separation between the regulation and the, in a restricted sense, realization of each of those partial moments (the separation between the cognition of the necessity of the action and the execution of the action itself) lacks any way of finding room inside the collective laborer. In brief, the action regulated under the form of dialectical cognition abolishes the separation between intellectual-labor and manual-labor. For the time being, this regulation of action is a necessary concrete form of capital. In turn, capital is the very negation of the consciously regulated process of social metabolism. Nevertheless, because of its very form, dialectical cognition carries in itself, as its own necessity, that necessity inherent in the process of social metabolism consciously regulated: the necessity of being the product of the freely associated individuals. In the development of the form of its process determining the necessary form of the social subject capable of realizing it, dialectical cognition makes evident, by its sole form, that it is only a potency of capital insofar as this one has its own annihilation through the development of the material conditions for the said conscious regulation, as its historical necessity. Only because it is thus determined by its specific form of ideal reproduction of reality as a class product, as the working class' science, scientific cognition frees itself from any ideological determination.

Marx's advance towards conscious revolutionary action; Marxism's retreat to ideology

Insofar as a simple regulation of the process of social metabolism through the valorization of value, capital does not find any limit to its development in the capacity of the reproduction of reality in thought for transforming nature into a means of human life. On the contrary; the complete development of this cognition is the realization itself of the conscious regulation of the process of social metabolism and, therefore, the overcoming of the limitations to that transformation of nature that arise from the necessary unconsciousness concerning the alienation of human potencies as capital's potencies. Still, it is also capital the one which carries in itself this necessity of annihilating itself. From which, the development of dialectical cognition as the necessary concrete form of realizing itself this capital's potency, unavoidably has to start by producing the consciousness of its own historical necessity; that is, by producing the consciousness of the specificity of the social forms that give birth to it. It is only upon recognizing itself in this, its own potentiality, that the ideal reproduction of reality is able to advance over the simply natural forms; and even, to face the cognition of its own concrete forms as such reproduction.

Karl Marx accomplished the original development of the ideal reproduction of the specificity of present-day process of social metabolism, of capitalism, until discovering its necessity to annihilate itself in the conscious regulation of the process of social metabolism. On doing so, he gave shape for the first time to the reproduction of a real necessity by means of thought. From Marx on, any process of cognition of this kind concerning social forms over which we need to act in a revolutionary manner is, in what is thus determined as its general part, a recognition process from the social point of view. Still, we can very well say that it is not about *reading Capital*; nor even about *studying* it. The point is to face capital's real forms by ourselves to ideally reproduce them, with the potency we acquire by having at our disposition their ideal reproduction developed in *Capital*. Actually, the development by oneself of this task is the only critical way to recognize the original specificity of Marx's procedure concerning scientific method. Any other way implies an attempt to unfold the real necessity that is present here in a mode external to it; therefore, it implies to represent this necessity. Nonetheless, it is fitted here for us to go on a little further into the question.

Hegel already clearly pointed out the difference between representation, whose development obeys a necessity external to its object, and dialectical cognition, that follows the unfolding of the necessity immanent to this object[17]. Nevertheless, he was unable to avoid the appearance that it is about the necessity of the Idea itself,

While he develops the ideal reproduction of capital's necessity, Marx stresses the specificity of the method he has discovered, in his well known remarks on scientific procedure. For instance, it is worth repeating here the already quoted 'It is, in fact, much easier to find by analysis the earthly core of religious mistiness than, conversely, from the real relations of life at each moment, to develop their celestial forms. The latter is the only materialistic and, therefore, scientific method.' Of course, Marx's most famous comment on the matter is the so frequently quoted one where he directly describes his research method and defines its result as the reproduction of reality in thought: 'The concrete is concrete because it is the synthesis of multiple determinations, therefore, the unity of diversity. It appears in thought then, as a process of synthesis, as a result, not as a point of departure, although it is the true point of departure, and, therefore, as well, the point of departure of intuition and of representation. In the first path [the analysis], the sheer representation was condensed to abstract determination; in the second one, abstract determinations lead to the reproduction of the concrete by the path of thought.'[18]

Nevertheless, Marx does not get to develop the specific difference between this scientific cognition that ideally reproduces the real necessity and theoretical cognition, that only represents it. In other words, he does not get to face this ideal reproduction as the critique - the supersession - of scientific theory itself. This happens to the extent that he refers to his own scientific works and discoveries as being of a theoretical nature. Certainly, in Marx's time scientific theory had not yet got to unfold its ideological determination as an apologetics of capitalism, no longer for its potency but, for its lack of potency to transform nature in full cognition of cause; that is to say, scientific theory did not yet need to boast about its own limits to consecrate the impossibility of the conscious regulation of social life. Marx was then able to advance for the first time in the ideal reproduction of the real forms of capitalist society until discovering its historical character, without confronting the necessity of making explicit the specific difference between that reproduction and theoretical representation, inasmuch as this difference embodies in the form itself of one and the other cognition process. Still, the sole materialization of this advance violently pushes scientific theory towards the exhaustion of its capacity for self-criticism in the complacency with respect to its own impotence.

What does Marxism have to say about the specificity of the method discovered by Marx? We can hardly find a more expressive synthesis than Lenin's non less widely quoted assertion 'If Marx did not leave behind him a "Logic" (with a capital letter), he did leave the *logic* of

Capital.'[19] Let us briefly unfold the point once more. Reality, matter, has the self-affirming by means of self-negation - the necessity of self-determining, contradiction - as its general form. Hence, each natural concrete form (and therefore, each natural form specifically developed as a social one) is the realized necessity of its abstract forms in their becoming, from the simplest one (matter as such), to one that negates itself as such concrete form (realized necessity) affirming itself as a potency (a necessity to be realized). Cognition is the way in which a subject regulates the realization of its own potency as the necessary concrete form of realizing a potency inherent in its environment, by appropriating these two potencies in their virtuality as purely such potencies. The subject of the cognition by means of ideas always starts by facing its object as something external to itself as such subject. Under its simplest form, this cognition reaches the necessity of the subject's own action just insofar as this one virtually manifests itself to the subject's mind as an immediate link between the mutual necessity of the subject and the object. Consequently, such form of cognition does not go beyond the very exteriority of the subject and of its object. It is determined, thus, as *immediate* ideal cognition. This cognition develops into cognition by means of thought when the subject goes beyond the immediate concrete forms to discover their necessity as realizations of their abstract forms. Nevertheless, on performing this advance, the subject comes up, first of all, against the exteriority of the abstract forms themselves; that is to say, the subject starts by ideally facing the abstract forms in what these forms have of realized necessity, under their appearance as purely concrete forms. From which, the appropriation of a real necessity in thought takes its most primitive specific form by ideally placing by itself in a causal relation the real forms (abstract and concrete ones) starting from the way they present themselves to it; that is, by mentally conceiving links among the real forms on the basis of their exteriority; and, therefore, independently from their necessity. Cognition becomes a mental construction that follows a causality alien to the real one: the ideal *representation* of reality. Logic is the scientific general form of this mental necessity. The appropriation in thought of the real forms in their virtuality transcends the exteriority of these forms by ideally accompanying them in the unfolding of their real necessity. In this way, scientific cognition mentally reproduces their real concatenations, thus taking the form of an ideal *reproduction* of reality. This cognition has no way of proceeding other than by making each real concrete form account for the necessity that it carries in itself as an already realized one, and each abstract real form, for the development of the necessity to be realized which it is.

Reality simply is the self-affirming by means of self-negation. Dialectical cognition, *dialectics*, is the method for virtually appropriating this contradiction that reality is, by following its development with our thought. Seen the other way round, dialectics does not belong in reality but in human cognition of reality; or, rather, it belongs in reality, in matter, in what this one takes its specific form of human cognition. This same condition applies to logic. Still, while the former can only take shape following the development of the necessity of a concrete real form, the latter necessarily has to take an autonomous incarnation as a condition for representing any concrete real form. Hence, any attempt to call the ideal reproduction of reality a logic, even runs into a formal impossibility: the absence of an independent body of ideal relations able to receive such a name. To pretend that logic remains effective in the ideal reproduction of reality, it is necessary to abstract it from its formal and historical determinations, turning it into a pure abstraction (just the same strategy needed to assume that the products of human labor have the form of commodities, or the means of production the form of capital, by nature). To avoid any confusion, we must not forget here the formal specificity of mathematical cognition as a necessary moment in the reproduction of reality in thought: to cognize the quantum of the magnitude of a real necessity in itself, we must naturally follow a logical necessity, due to the actual specificity of quantity as the form of the self-affirming by means of the negation of self-negation.

---

[19] Lenin, V. I. 'Philosophical Notebooks' *Collected Works* vol. 38 Moscow: Foreign Languages Publishing House, 1961.

The certainty about the need of a logic to appropriate reality in thought inevitably implies that the real forms are taken as if they were incapable of being the realization of their own necessity, as if life were to be insufflated to them by the cognition process itself. Representations, whether on an idealist or a materialist basis, cannot avoid carrying in themselves this appearance. Let us look at it a little closer. To assert the need of a logical necessity to apprehend in thought any real form means, by itself, to assert that this real form has no necessity of its own to be mentally followed: being there a real necessity, why should we appeal to a mental one instead of just following it through its development, with our thought? Hence, real forms appear as being unable to relate, to move, by themselves at the beginning of the representation process. But they emerge from this process overflowing with relations. Hegel just sticks to this appearance up to its end. He gives logic as its content, that is, as the content of the abstractly ideal necessity, the general form of the development in thought of the real necessity, placed not as the ideal reproduction of matter but as the development of the real necessity itself. Dialectics is thus inverted, appearing as the development of the Idea placed as the real subject that engenders matter. On doing so, Hegel pushed representation beyond its limits. The real necessity was laid there with its strength unchained, ready to be called into action. Naturally, standing dialectics on its feet after such inversion has nothing to do with entering ‘matter’ where Hegel writes ‘idea’ and vice versa.

Marx gives a first step in putting dialectics right side up by opposing to the claim of generality of Hegel’s logic concept, ‘the peculiar logic of the peculiar object’[20]. ‘The peculiar logic of the peculiar object’ already excludes by itself the possibility for logic to take a general body as the ideal necessity that cognition must follow and, therefore, its possibility to exist by itself. And what can the ‘the peculiar logic of the peculiar object’ be, but the reflection in thought of the development of the real object’s own specific necessity? Nevertheless, Marx still has not completely developed here the distinction between the ideally produced necessity, the logic, that is, the discursive reason, that takes the place of the real causality in the representation and this real causality itself. It happens that Marx has not gone yet beyond the boundaries of philosophy; so much so, that he still identifies the abolition of the proletariat with the realization of philosophy[21]. But, immediately after in the same year, 1844, Marx faces for the first time the economic determinations of capital as the alienated general social relation of present-day humanity. On doing it, he discovers for the first time in history the real necessity of philosophy as a concrete form of alienated consciousness and how Hegel has developed it to its end. Consequently, Marx does no longer criticizes logic for being a general ideal necessity that displaces a peculiar ideal necessity. He criticizes logic for being an ideal necessity itself that displaces the real necessity that has to be followed in thought to rule one’s conscious transforming action. That is, he criticizes logic for its very essence as a discursive reason that represents the real reason in thought, as the necessary form in which alienated thought takes shape: ‘In turn, the philosophical spirit is nothing but the alienated spirit of the world that thinks inside its self-alienation, that is, that captures itself in an abstract way. *Logic* [the pure *speculative thought*] is the *money* of spirit, the speculative, the *thought-out value*, of man and of nature; its essence that has become completely indifferent to any real determination and which is, therefore, unreal; it is the alienated thought that hence abstracts from nature and the real man; the *abstract* thought.'[22] A little later, in 1847, Marx develops the specific critique of dialectical logic, showing step by step how this 'absolute method' starts from categories (that is, from the ideal representation of the real forms) and unavoidably ends up by representing itself as the one who engenders the real forms (Hegel) or by succumbing to its own contradictions (Proudhon)[23].

[21] Marx, Karl ‘Crítica de "La filosofía del derecho" de Hegel. Introducción’ *Obras fundamentales de Marx y Engels* Vol. I, México: Fondo de Cultura Económica, 1982 (‘Critique of Hegel’s Philosophy of Right. Introduction’).

Hegel's inversion is embodied in the form itself of the process of cognition; it is embodied in the conception of this process as a logical one. In fact, to proclaim logic as an inescapable condition for scientific cognition is nothing but to consecrate the idealist inversion, that prioritizes a mental necessity over matter's necessity. To say it once more, the question is not to give rise to a new logic, but to free science from it. Precisely what Marx has done. The claim for a logic in *Capital* is a contradiction in terms. This is something that Marx himself remarks in his comments on Wagner[24]. And, by the way, for the same reason there is not a single invocation in Marx to a dialectical logic, nor to a logic in general, there is not to dialectical materialism, to historical materialism or to other such *categories* either, that can only be used to *conceive* the real materiality and the real history as the corresponding abstractions.

Nevertheless, according to Marxism everything comes down to inverting dialectics again just by turning into a common place the representation of its development accomplished by Marx as its opposite, as if it were the development of a *dialectical logic*. And it is thus that, by force of abstracting from the real form that is the object of cognition and from the form of the process of cognition, it ends up putting dialectics completely upside-down again, by representing the real necessity of the real object as the 'inner logic' of an abstract ideally 'pure' form of it[25].

Real relations are nothing else than the concrete forms the necessity of self-affirming through self-negation takes on realizing itself. There is no place for 'external' relations and, hence, for 'internal' relations, among real forms. Concrete forms are the realized forms of the necessity that determines their abstract forms as such, and therefore, this necessity in action through the concrete forms now taken by its potency. But theoretical representation starts by replacing the real necessity with a logical necessity. The necessity itself that determines each real form thus appears as being placed outside it. On which, abstract forms and their concrete forms, and these concrete forms among themselves, appear to be externally related to each other. Real relations, that is, determinations, appear in representation degraded to the category of external relations. The abstract form stands here and, alongside it, the concrete form stands there, with logic placing them into relation. Dialectical logic does it by taking them as the opposites that antagonize or interpenetrate each other, thus representing determination as the unity of these opposites. Of course, for a concrete form to oppose this way its own abstract form, it must be the realization of a necessity neither more nor less developed than the necessity that determines the latter. Therefore, the existence of the concrete form results thus represented as preceding its own determination. Since it stands on this basis, Marxism cannot avoid fluctuating from representing the superstructure as the mere reflection of the base[26], to representing the superstructure being the determinant itself of social organization[27]. Or it makes one piece of the whole fluctuation, by asserting that the base determines the superstructure, but, in turn, the superstructure determines the base, but the base determines the superstructure in the last instance, but the superstructure has a relative autonomy with a dominant instance, until this string of enunciated determinations comes to an end by being named 'over-determination'[28]. Still, what actually is to determine, in whichever instance? What is a relative autonomy? is it about the autonomy a dog tied by a chain has? (this is not a joke, but a real statement once published in *Capital & Class*). Marxism has no answer to these questions, beyond naming the jumping from the base to the superstructure, and from the superstructure to the base, a 'dialectical relation.' And not a single step towards unfolding the development itself of the real necessity is given by representing it as a matter of the base 'producing' the superstructure and the superstructure 'helping' the base[29] or of the mutual 'ensemble' of structures 'conditioning or limiting' action and action or strategy 'recursively reproducing or transforming' structures or society[30]; or a matter of material productive forces having 'the primacy' over relations of production and actions being 'functional' to structures 'through human rationality'[31], or of social being and social consciousness mediated by 'experience'[32]. No wonder all this ends up giving rise to the belief that, since everything determines everything and is determined by everything, conscious revolutionary action must give way to ideologically based action, that is, to its very negation[33].

The point is not to label 'internal', such irreducibly external relations as 'conditioning', 'limiting', 'primacy', 'functionality,' etc., as dialectical logic does[34]. The point is to follow the real necessity in its development, to discover how the human material forces of production (through which the human process of social metabolism realizes its generic necessity of appropriating nature to produce itself) negate themselves as simply such to affirm themselves by realizing their potential necessity of regulating their own realization, specifying themselves under their concrete form of relations of production. For being thus determined, the relations of production negate themselves as such concrete forms, affirming themselves as a potential necessity that realizes itself (that is, that affirms itself by negating itself as such potency), specifying itself as the voluntary action of the individuals. In other words, the relations of production are the realized necessity of the material productive forces to regulate themselves that, as such, have the regulated realization of these forces in the voluntary action of the individuals, as their own potential necessity. And this voluntary action is the realized necessity of the relation of production that has the realization of the process of social metabolism through the processes of metabolism of the individuals, as its own potential necessity.

As far as the alienation of the generic human potencies impedes the regulation of the process of social metabolism to present itself as such to the individual's consciousness, the material productive forces and the specific form they take as relations of production on regulating themselves, negate themselves as simply such, to affirm themselves as the economic base of society. This base has as its potential necessity, that of regulating its own realization by specifying itself as the superstructure of the legal, political, etc. relations. In turn, this superstructure has as its own potential necessity, that of realizing itself in the voluntary action ruled by a consciousness limited to the appearances of its own necessity, that starts to be such by seeing itself, not as the expression of alienated consciousness, but as the expression of an abstractly free consciousness. In brief, the superstructure is the realized necessity of the material productive forces of society to regulate themselves through apparently conscious individual action and, therefore, this very forces in action.

The real necessity we have been following keeps the form of a simple potency along the abstract forms it takes in its development. This is what makes these abstract forms always appear as being coexistent with their concrete forms, when they are externally seen. Still, inside each step given by their metamorphosis, these simple necessities take the form of possibility and, moreover, of possibility mediated by possibility itself in its realization, as the necessary form of realizing themselves. This is what makes the concrete forms appear as being self-determined. Specially, it makes voluntary action appear as having no determination other than itself, when it is externally seen. And even, on giving a step forward into the field of representation, it makes voluntary action appear completely inverted as determining by itself the material productive forces of society, when it actually has the power to transform these forces because it is their most developed concrete form, that is, because it is determined by these forces insofar as a possible potency, as the necessary form they take to realize their own necessity. And it is on realizing this necessity that determines it as a possible potency, that human action historically becomes an action that rules itself by thoroughly cognizing the necessity that it realizes, that is, its own necessity, by reproducing it in thought: the free action through which the consciously regulated process of social metabolism takes concrete shape.

Nevertheless, Marxism cannot overcome the inversion of the real necessity in the logical representation without overcoming itself. Thus, R. Gunn[35] advances far enough in his critique of scientific theory as to realize that the clue is present in the difference between the abstract forms that have a purely mental necessity (which he represents as empirical abstractions) and the reflection in thought of the abstract real forms (represented as determined abstractions). Just one further step seems to remain for Gunn to discover that this difference must necessarily arise from an essential difference in the form itself of the cognition process from which each type of abstract form emerges. It is the difference that runs from constructing abstract forms through logical analysis, to analytically discovering the abstract forms by following the inverse course to the development of its real necessity; and, then, the difference that runs from mentally constructing concrete forms by placing the abstract forms in the relations determined by the same logic, to the reproduction in thought of the realization of the necessity of the abstract forms in their transformation into concrete ones. Still, to give this step and to discover capital as the concrete social subject in which all human potencies take shape today, or in other words, to discover the necessity of human action in the wholeness of its present determination, are the same thing. Instead of making evident the form of the real necessity, thus closing any appearance of freedom as an abstract self-determination on discovering it as the cognition of the necessity of one's own determination[36], Gunn steps back. Not in vain he professes a Marxism that places what is the necessary concrete form of realizing the accumulation of capital, class struggle, as the cause of this accumulation[37]. Had Gunn followed the development of the real necessity, he would have seen that there is no direct relation between two real forms other than being one the realization of the other's necessity; and that only for being such realization, it can be said that the former is the form of existence of the latter. Nevertheless, Gunn sticks to representation as the only form of scientific cognition. He thus conceives as irremediably external, the real relation of the genus with its species, i.e., the realization of its possible necessity by the abstract form, which thus affirms itself through its own negation becoming a concrete one. Once done this, he represents the concrete forms ('conjuncture') as a 'constellation' of abstract forms. This relation has nothing of an 'internal' one but its being presented as such by Gunn, as even its very name tells us about its externality. Of course, any form can be represented in this relation as the determinant of any other, and therefore, can be represented as the form of existence of any other. Hence, all real necessity ends up degraded to the question of deciding, from 'the indefinite range of what can be inferred from a contradiction', which ones are the 'pointfulness inferences', by resorting to interpretation. Remarkably close to where G. Carchedi arrives when he asserts that: 'In terms of concrete realization, determination means simply mutual interrelation.'[38]

---

[35] Gunn, Richard 'Against Historical Materialism' *Open Marxism, Volume II, Theory and Practice* London: Pluto Press, 1992.

P. Murray, too, comes to face the difference between the abstract forms that have a purely mental necessity ('general abstractions') and the reflection in thought of the abstract real forms ('determined abstractions') as the clue to the scope of scientific cognition. Still, he cannot go beyond this point either, to face the development itself of the real necessity, and he draws back to the same hindrance of interpretation. Only that, instead of a class antagonism abstracted from its determinations, Murray ends up placing a scientific morality equally abstracted from its determinations, as the motive of conscious action[39].

Engels points out how Marx made clear he was not a Marxist. Considering what they call themselves, we must assume that Marxists can only see in Marx's assertion an expression of insincere modesty, or of his sense of humor, as Althusser wants to. It happens that, opposite to Marx, *they really are* Marxists. As its very name shows, *Marxism* is the conception of the *reproduction* in thought of the specificity of present-day society - originally developed by Marx - as a *representation* of this specificity; and, hence, the representation of dialectical cognition as a *conception of the world*, as *a system of thought*. In brief, it is the degradation of the integral cognition of one's own necessity to *an interpretation* of reality and, therefore, to an *ideology*. It is not surprising then, that even though Marxism is always willing to state the historical nature of capitalism and its concrete forms, the idea that scientific theory is one of these never crosses its mind. It happens that in scientific theory, ideology takes the form of its opposite, of scientific method.

[38] Carchedi, Guglielmo *Class ..., op. cit.*.

[39] Murray, Patrick *Marx's ..., op. cit.*.

Thus, like any other scientific theory about present-day social forms, Marxism shows its own necessity insofar as a concrete form of alienated consciousness by representing itself as the abstract negation of alienated consciousness, as an abstractly free consciousness. But here it is where its dialectic materialist logic shows the *raison d'être* for its specificity, for representing the simplest real determination, the self-affirming through self-negation, as the unity of two immediate affirmations mutually opposed and, therefore, for representing the existence of the concrete forms as abstractly opposed to their own determination. Marxism does not represent itself just as an abstract free consciousness, but, by invoking dialectical logic, it represents itself as the abstract free consciousness placed by itself as the opposite pole of the consciousness alienated in capital. Marxism does not see itself as being the opposite of alienated consciousness for recognizing itself as a form of existence of capital; on the contrary, it sees itself as the absolute realized negation of capital, as a social form whose necessity is external to capital. From this point of view, capital's historically immanent necessity of annihilating itself in its own development, that determines the working class as the necessary personification of this annihilation, comes down to an action external to that development itself. And, consequently, the performer of this action comes down to an abstract opposite of capitalism that, at best, has its necessity related to this one's as its absolute realized negativity, to the working class that reacts in self-defense against capitalistic misery and oppression. With which, the revolutionary realization of socialism/communism does no longer appear as what it is, as the realization of the historical necessity of the general regulation of the present-day process of social metabolism (and therefore, as the ruling itself of this process in action), as the realization of the historically own necessity of today's general social relation. On the contrary, the working class' revolutionary action sees its necessity come down to the 'will to survive' or the 'libertarian spirit' themselves of the working class, to the 'moral superiority' of a system over the other, to the realization of 'social justice'; that is, sees its necessity come down to a collection of abstractions that cannot but ideologically reflect the alienation of human potencies as capital's potencies, but that are represented as being so naturally eternal that the society freed from all alienation could only be realized through them.

It is precisely through this seeing itself as being abstractly free, that this specific form of alienated consciousness realizes its necessity as a concrete form of the alienated consciousness that does but to affirm itself as such. On the contrary, it is about the conscious regulation of the working class' revolutionary action through which capital realizes its necessity of annihilating itself into the general conscious regulation of human life. Therefore, it is not about producing an abstractly free conscious action, but about the production of an alienated consciousness, indeed, but one that is only such insofar as it is the negation of the negation of free consciousness. Although the question immediately arises, only its statement corresponds here: which social necessity embodies in the inversion, unconditionally accepted today among apparently uncompromising critical scientists, of the ideal reproduction of capitalist society accomplished by Marx into a theoretical representation?

As Marx shows, the point is not to interpret the world. The point is that the transformation of the world in question is the development of the conscious regulation of the process of social metabolism, and, therefore, the supersession of interpretation itself. If we fill any urgency to paraphrase Marx's thesis, we can state it as 'Philosophers have only *interpreted* the world in different ways; as a necessary form of scientific cognition alienated in capital, scientific theory can only rule its transformation within the miserable limits of the appropriation of relative surplus value; the point is to *change* it beyond these limits.' Above all, the scientific critique of scientific theory is the development of this conscious regulation, the development of the organicity of the working class' revolutionary action.

Appendix

Capital’s Development into Conscious Revolutionary Action
Critique of Scientific Theory

(Scheme)

Juan Iñigo

I. Dialectical cognition

1. *Dialectical cognition, i.e., the regulation of action under its form of reproduction of one’s own necessity in thought*: from the immediateness of action to the determination of its concrete subject (the development of necessity into its concrete form of freedom), the concrete forms of the ideal reproduction of reality (the method of dialectical cognition).

2. *Mathematical cognition, i.e., the cognition of the measure of one’s own necessity*: the determination that negates itself as such (the self-affirming by means of the negation of self-negation) and the lack of a real necessity whose development is to be ideally reproduced; the concrete form of measuring the quantum of magnitude, i.e., the mathematical process of cognition: from the representation of quantitative relations as abstractly such (logic) to the representation of the measure of the real abstract forms by the relations of measure of their concrete forms.

3. *Critical history of the forms of mathematical representation, i.e., the development of mathematics as a formally historic process in itself*: the emptying of the specificity of quantitative determination in formal logic; the reintroduction of quantitative specificity as abstract extensiveness; the mutilation of the logical development of the relation between the unit and the multiplicity until they reach their identity in the number, with the following inversion of the representation of this development as mathematical analysis, abstract algebra and topological relations.

4. *Mathematics of time-space, i.e., the measure of one’s own necessity specifically determined as the abstract self-reproduction of quantity*: the specific forms of time-space and their representation; critique of physics and its inverted determinations, where the forms in which phenomena manifest themselves are placed as their causal law.

II. The historical determination of dialectical cognition

5. *The development of matter into the generic human being*: the determination of matter as a general historical natural development, i.e., as universe; life: the regulation of the individual process of metabolism, the regulation of the simple process of social metabolism, from animal specificity to generic human being.

6. *The development of the generic human being into capital, i.e., the alienation of human potencies as capital’s potencies*: the general regulation of the process of social metabolism by means of the ideal appropriation of reality; the autonomously regulated system of social metabolism; capital’s historical potencies: towards the conscious regulation of the process of social metabolism.

7. *Consciousness as capital's potency, i.e., alienated consciousness*: the development of the commodity into mutual individual independence as a form of general social interdependence; the individual concrete form of social regulation; the incompatibility of capital with dialectical cognition as the general form of scientific cognition.

8. *Scientific theory, i.e., the science of capital insofar as it is purely determined by the appropriation of surplus-value*: the resolution of the contradiction between capital's necessity to submit all production and consumption to science and capital's necessity of alienated consciousness: the theoretical representation of reality by the relations of measure of its concrete forms; ideology in the form of the method of scientific cognition.

9. *Marxism*, i.e., the conception of the *reproduction* in thought of the specificity of present-day society, originally developed by Marx, as a *representation* of this specificity and, therefore, as a *conception of the world*, a *system of thought*: its historical necessity and its concrete forms.

III. Scientific cognition as a necessary concrete form of revolutionary action

10. *Conscious revolutionary action as the negation of the negation of free action*: the political organization of the working class and the unfolding of scientific cognition.

Juan Iñigo Carrera

Argentina: The Reproduction of Capital Accumulation through Political Crisis

> And all science would be superfluous if the form of appearance of things directly coincided with their essence.[1]
>
> Se vogliamo che tutto rimanga come é, bisogna che tutto cambi.[2]

In her article, 'The Battle of Buenos Aires: Crisis, Insurrection and the Reinvention of Politics in Argentina', Ana Dinerstein presents a thesis which bears much relevance for the Argentine working class. According to Dinerstein, the events of 19–20 December 2001 in the Plaza de Mayo brought about a fundamental change in the way politics is practised in Argentina. Moreover, the nature of this change is impossible to miss, clearly pointing as it does towards a new form of political action directed at superseding the capitalist mode of production.

Dinerstein bases her thesis on four points related to the people's march on the Plaza de Mayo: a) its broad-based appeal; b) its spontaneity and horizontal organisation; c) its demand 'all of them must go!'

---

[*¡qué se vayan todos!*]; and, finally, d) the projection of these trends into the neighbourhood assemblies, the barter clubs, the factories turned into co-operatives, and others.

Certainly, Dinerstein is not alone in her analysis and conclusions. On the contrary, she presents a point of view that is widely shared among those who advocate radical change in Argentine society. Beyond their particularities, a broad range of participants and observers share this view, ranging from the 'traditional' revolutionary Left to the supporters of the 'new social subjects'.[3] Even at international level, the Argentine case is seen as paradigmatic, representative of the rise of a new social subject able to overthrow capitalist society.[4] We shall analyse Dinerstein's paper within this framework and follow the path she suggests.

Let us start with Dinerstein's first premise: the magnitude of the events of 19–20 December 2001 in the Plaza de Mayo. As Dinerstein writes:

> The battle of Buenos Aires lasted 10 hours. During the confrontations between demonstrators and the police, hundreds were arrested, six people were killed and many injured.[5]

Simply in terms of size, however, a different type of popular action actually accounted for 9 deaths and 2,717 arrests in the Greater Buenos Aires area alone during those days, and for a total of 29 deaths and 4,500 arrests in the country as a whole.[6] What sort of popular action was this that such figures only receive a footnote from Dinerstein, and a rather ambiguous one at that?[7]

The answer is looting. Neither these figures nor the acts themselves are given much significance in Dinerstein's presentation. They are only referred to once, as an occurrence that took place before the 'real' political events: the *cacerolazos* – the banging of pots and pans – and the march on the Plaza de Mayo.[8] Dinerstein is not the only one to disregard looting as a key feature of the political events of December 2001,[9] and this glaring omission is particularly noticeable in those studies that ascribe the rise of a new political subject in Argentina to the December 2001 events.[10]

---

[3] Compare, for instance, Altamira 2002 and Bonnet 2002.

[4] See Holloway 2002b, Petras and Veltmeyer 2002.

[5] Dinerstein 2002, p. 23.

[6] Anonymous 2002a, p. 17. The actual number of deaths during the looting spree could be significantly higher. According to direct witnesses, for example, four people were killed simply during the looting of a supermarket in José C. Paz. None of these deaths were officially registered.

[7] Dinerstein 2002, p. 23.

[8] Dinerstein 2002, p. 22.

[9] See, for example, Petras and Veltmeyer 2002.

Are we to believe that the looting was not a political event? In fact, the government did not establish a state of siege as a result of the *cacerolazos*, as Dinerstein asserts.[11] The state of siege was declared several hours before the first pot was banged, in response to widespread looting. Why, then, is it that the looting is infallibly the *bête noir* in those studies that present December 2001 as a turning point in the way political action is carried out in Argentina?

The looting

In order to bring out the political significance of looting in relation to the *cacerolazos* and the march on the Plaza de Mayo, let us briefly consider the structure of the City of Buenos Aires and its suburbs, the Greater Buenos Aires region. This urban conglomerate is situated on the shores of the River Plate. Broadly speaking, it consists of the nucleus of the City of Buenos Aires, the seat of national government, surrounded by two semicircular belts. Notwithstanding the existence of neighbourhoods which are visibly different from each other within each of the three zones, the following table provides a general overview of the situation in October 2001:

Table 1
Unemployment and poverty in the Greater Buenos Aires, October 2001[12]

	Population (millions)	**% of the Economically Active Population**		**% of total population below the line of:**	
		Unemployed	**Under-employed**	**Poverty**	**Extreme poverty**
City of Buenos Aires	3.0	14.3	11.8	9.8	2.1
First Greater Buenos Aires Belt	3.0	17.8	15.7	26.6	6.8
Second Greater Buenos Aires Belt	6.6	22.8	19.9	51.1	19.3

---

[10] See Colectivo Situaciones 2002.

[11] Dinerstein 2002, p. 23.

[12] Source: 'Encuesta Permanente de Hogares', Instituto Nacional de Estadística y Censos (INDEC). See INDEC 2002. The figures include the newly-urbanised areas which lie next to the traditional limits of the Greater Buenos Aires. Extreme poverty means an income below that needed to purchase the most basic food basket without even taking rent into consideration.

The *cacerolazos* and the march on the Plaza de Mayo only took place in the City of Buenos Aires and the more prosperous neighbouring suburbs. Beyond these areas, however, they were strange and far-removed events observed on television. On the other hand, looting was a common event in the outlying areas and extended into the poorest neighbourhoods of the City of Buenos Aires. In this case, the television audience was made up of the more skilled workers and the plentiful petty bourgeoisie, worried by the possibility that the looting mobs might make a move on their own neighbourhoods.[13]

No careful observer could miss the lines of four-wheel drives and other deluxe cars echoing the *cacerolazos* as they paraded in protest before the elegant residence of the displaced minister of economy, Cavallo, the champion of convertibility. Thanks to convertibility, the most prosperous supporters of neoliberalism had been able to import these vehicles. But the recently imposed *corralito* (literally, small fencing or enclosure) on bank deposits had revealed to them the true colours of this 'false idol' and, they felt, it was time to tear it down.

Conversely, looting was a phenomenon which evinced very little spontaneous political action, let alone elements of a horizontal political organisation. Clearly, looting was rooted in the hopeless misery to which the Argentine working class was finding itself condemned by the inexorable path followed by capital accumulation. But it is noticeable that, after December 2001, no more looting took place despite the fact that unemployment soared and real wages plunged.

It is well known that, in the province of Buenos Aires, it was the apparatus of the Justicialista Party (official name of the Peronist Party) that had prompted the looting. This apparatus was commanded by Duhalde, who was finally appointed president in the aftermath of December 2001.[14] The Peronist local leaders [*punteros*] drew people out by announcing locations where food was supposed to be distributed for free. Then their cadres spearheaded the looting.[15] Let us consider a specific case – that of the district of San Miguel, one of the poorer areas of the Second (urban) Belt around the Argentine capital, governed by Aldo Rico. Rico is a former army officer who led a military coup in 1987 in support of the torturers and murderers of the 30,000 *desaparecidos* of the 1976–83 military dictatorship. In 1999, he was elected mayor of San Miguel with 68% of the votes, supported by Duhalde. Now, Rico set up an operation aimed at driving the potential looters to the borders of his district, giving them *carte blanche* to act from there onwards.[16]

---

[13] To avoid any misunderstanding, note that by 'working class' I refer to the totality of the members of society that are separated from their means of production and only own their labour-power, selling it in order to materially reproduce their lives, whatever the intensity, complexity and productivity of their work. My use of 'working class' does not depend on the price of their labour-power, on whether it is productive or unproductive with regards to the valorisation of capital, or on whether workers are able to sell it, in whatever the way they relate to commodity production. By petty bourgeoisie I mean the genuine independent producers of commodities, the individual merchants and the capitalists whose capital falls short of the amount needed to actively participate in the formation of the general rate of profit.

[14] In the 1999 presidential elections, Duhalde was defeated by De La Rúa, from the Alianza Party, who fled the country on 20 December.

In fact, the Justicialista party had already resorted to this course of action in 1989, when a wave of looting was a key factor for the premature transfer of power to president Menem.

Therefore, the fall of the national government on 20 December 2001 was precipitated by the confluence of two forms of popular political action. Looting was clearly the dominant form within the areas of greater poverty furthest away from the city centre. It was articulated by a political structure that grew in proportion to the deteriorating conditions for the reproduction of the labouring population. This structure is based on a complex relationship within which political action, clientelism, crime, *barras bravas* [hooligans] and police impunity all come together.[17] Within the more prosperous areas located closer to the city centre, the *cacerolazos* and the march on the Plaza de Mayo were the principal form of protest. These were spontaneous movements that coincided with the mobilisation of the left-wing parties under the motto 'all of them must go!'.

This twofold process raises a further issue: the identity of the determining factor underlying the two forms of action in question, apparently opposed in terms of both political form and content, but which fused, bringing on the fall of the Alianza government. To answer this question we must start by considering the course followed by the national process of capital accumulation that culminated in those actions.

The specific trend towards economic contraction

Dinerstein states that:

> One of the keys to understanding why the convertibility plan did not produce the macroeconomic conditions for sustained growth and, instead, led to the crisis of December 2001 lies in the fact that, during the 1990s the private sector produced deficit in the generation of foreign currency for the country . . . with their commercial and financial transactions with the world. The negative balance was covered by the public sector which indebted itself to cover the difference and thus accumulate reserves to expand domestic credit.'[18]

All this accentuated the vulnerability of the plan 'to the capricious movement of global capital and financial markets'.[19] Then, the escalating 'tension between persistent social and labour struggles and the pressure from financial institutions'[20] produced political instability, which, in turn, produced 'further economic instability'.[21] And so on until the crisis exploded in December 2001.

But what economic growth are we talking about? The physical volume of social production evinced substantial growth during the 1990s, even more so than that of the USA. During 1990–2001, the average physical volume of the Gross Domestic Product (GDP) grew 26% more than levels reached during the previous stagnation of 1975–89 and 74% more than levels reached during the previous sustained growth period of 1960–74.[22]

This growth is the mainstay of the arguments presented by the supporters of neoliberal policies who claim that the crisis resulted from an incomplete application of these policies, creating a climate of political instability. In turn, this climate purportedly generated fear in investors, causing the withdrawal and flight of international capital.[23] As we can see, however, despite standing in opposite corners over 'the struggle between money and life',[24] both Dinerstein and the defenders of neoliberalism agree that the origins of the December 2001 crisis lie in the very political forms themselves. Posited on the side of 'life', this conception might appear to be a revolutionary-critical perspective concerning the abolition of the capitalist mode of production. However, it actually implies an idealistic inversion of the determination of working-class consciousness, which becomes reduced to the appearances of its advances and retreats in political struggle.

[24] Dinerstein 2002, p. 22.

The consciousness of the Argentine working class is no more than the expression of its social being. This social being is concretely determined by the specific way in which the material production of its life is organised. Clearly, the issue concerns what is to be done regarding the current political situation in Argentina so that this action can express the general interests of the working class.[25] To do so, we must start by bringing to light the concrete historical powers of the Argentine working class. Therefore, we need to begin by taking a look at the specific nature of the Argentine process of capital accumulation.

In other words, we must avoid embracing the illusion that an apparent rise in the political awareness of the Argentine people will *per se* engender a radical change in the national process of capital accumulation. The point is to examine what has changed in the process of capital accumulation in Argentina that has prompted it to take specific political form in the shape of direct popular action. Thus, it will be possible to unveil the historic potential that lies within such action.

Let us take another look at the growth of the Argentine social product during convertibility from the specific point of view of capital accumulation. As we well know, in those societies where the capitalist mode of production dominates, social wealth does not simply appear as the material accumulation of use-values but, rather, as the accumulation of value. In other words, it is clearly not enough to merely possess more goods in order to be wealthier; what really matters is the total value of those goods. This is a delicate issue for the Argentine economy, where, particularly over the last decade, complex industrial production has been overtaken by imports while only the production of raw materials and very low value-added activities have expanded.

In real terms of purchasing power, average GDP grew only 24% from the 1960–74 period in comparison to the 1990–2001 period. Even worse, during the latter interval it fell to 10% below the level reached 1975–89.[26] During a time of apparently sustained growth in physical volume, the Argentine economy actually lost a tenth of its value. In 2001, it was 9% below the value it had reached in 1974. Hence, the expanded physical volume of material products pointed to a contracted mass of social wealth. The annual value product of the Argentine economy has remained stagnant – if not actually shrunk – during the last twenty-five years.

---

[25] Marx and Engels 1976, p. 497.

In short: in 1960–74, the value of Argentine GDP was equal to a monthly equivalent of 18 million of the staple goods baskets that are used to compute the consumer price index. In 1975–89, it grew to 24 million baskets, yet fell to 22 million in 1990–2001.[27] Meanwhile, the average population grew from 23 million to 29 million, and to 34 million, respectively.[28] In 1960, the Argentine economy was equivalent to 3.2% of the USA economy; in 2001 this proportion had fallen to 1.5%.[29] It was from these already contracted levels that the 7% fall in value which took place in the crisis of 2002 (corresponding to an 11% fall in volume) occurred.

However, the issue does not end here. We also know that capitalist production does not merely aim at the production of value. It aims at the production of surplus-value. Total net surplus-value[30] increased by 90% between 1960–74 and 1975–89, although total value grew only 40%. Still, the 10% fall in the value product between 1975–89 and 1990–2001 allowed for only an increase of 8% in net surplus-value.[31] Moreover, total surplus-value did not end up falling in absolute terms, because it was sustained at the expense of undermining the normal reproduction of capital accumulation at its very base, namely, by increasingly paying labour-power below its value. Many years before the current crisis, the national process of capital accumulation began to show a specific trend towards the formation of a surplus-labouring population. This trend immediately results from the stagnation and contraction of the amount of value produced by the Argentine economy. During 1990–2001, the real industrial wage fell 35% with respect to 1960–74 and 23% with respect to 1975–89.[32] At the same time, legislation slashed indirect wages by at least a third, which, in practice, was much more owing to the expanding informal economy and deteriorating pension and health systems. Thus, the Argentine working class has been increasingly prevented from reproducing its labour-power with the productive attributes it had developed before the stagnation and contraction began. The Argentine economy does not only come up against a specific limit to its growth but, as it is absolutely unable to reproduce the labour-power it once required, it collides with the general base of capital accumulation itself.

The specific form of capital accumulation in Argentina[33]

At first sight, it appears that the Argentine economy has developed along the general lines inherent to the national processes of accumulation of industrial capital. There is a clear trend towards the centralisation of capital and a strong presence of the world's most concentrated capitals. Yet a peculiarity immediately emerges. These capitals work on a scale restricted to the size of the internal market. How do they fit into a market of only 36 million inhabitants, almost half of whom live below the poverty line today and whose average wage is just one tenth of the American wage? For instance, six of the world's main car manufacturers still have production plants in Argentina. Each export to the Mercosur zone is met by an import, thus balancing out any expansion of the scale of production, beyond that of the internal market. Conversely, in Italy, with a population that is two thirds larger and an average wage close to the American one, there is only one car manufacturer which is, furthermore, unable to sustain independent capital ownership.

The answer lies in the scale of the Argentine plants, which is small compared to that of other plants managed by the very same capitals which supply bigger internal markets or the world market. Yet, this small scale, and its negative consequences upon technical innovation, mean lower labour productivity, and thus higher production costs leading to the impossibility of valorising capital at the general rate of profit. Therefore, in addition to the surplus-value simply extracted by industrial capital from its productive workers, the capitals in question need to find, within the Argentine economy, an additional source of social wealth to compensate them for their limited production scale.

---

[32] Iñigo Carrera 2002, p. 20; see the methodological criteria on pp. 19–20, and the data table on p. 32, based on original information from INDEC.

[33] This section is based on Iñigo Carrera 1998.

Today, the sale of labour-power below its value accounts for a significant part of the compensation. Still, this relative cheapness cannot be – nor could it ever have been historically – its main source. Had this been the case, industrial capitals would have generated production from Argentina for the world market as the norm, instead of restricting their scales of production to the domestic market.

A second source of compensation arises from the pervasive presence of small national capitals. Their accumulation is not directly ruled by the general rate of profit, but by the rate of interest. When the price of production of their commodities pushes their profitability over this limit, the competition among them means that the profit at stake ends up being transferred to the more concentrated capitals to which they relate in circulation.[34]

However, historically, the main source of compensation has always been the differential ground rent from the Argentine *pampas* – more recently, the differential rent coming from oil, gas and hydroelectric energy has also acquired relevance. Landowners, on the one hand, and the international industrial capitals that operate as restricted fragments in Argentina, plus the more concentrated national industrial capitals, on the other hand, are, albeit antagonistically, associated to appropriate the differential ground rent. This shared appropriation underlies the whole specificity of the Argentine national process of capital accumulation. This is where the current stagnation and ensuing crisis have their specific roots.

Industrial capitals have appropriated their share in differential ground rent through different means. In some cases, this originates in the flow of rent to the state through special taxes on agricultural exports, regulated prices or the monopoly on foreign trade. The rent is then transferred to industrial capitalists as subsidies, the purchase of commodities by the state and by its workers, and so on. In other cases, the state controls the flow in an indirect way. For instance, this can occur through a fiscal deficit covered by the inflationary printing of currency, which leads to a negative rate of interest in real terms, and in which the landowners are creditors and industrial capitals are debtors. Another significant way is the overvaluation of national currency. When agricultural exports pass through the exchange mediation, overvaluation retains a share of their value that corresponds to ground rent. The industrial capitals are then able to appropriate this because the overvalued national currency allows them to import means of production at a lower cost than the price of production on the world market. Overvaluation, moreover, multiplies the value of profits made locally in international terms when they are remitted abroad. In fact, overvaluation has been the prevailing method for appropriation throughout the last decade, which fell into a violent crisis in 2001.[35]

---

[34] For this determination of differential concrete rates of profit, in opposition to the theories that ascribe these differences to market forms, see Iñigo Carrera 2003, pp. 123–30.

The paths taken by the appropriation of ground rent do not impinge on the normal profitability of agricultural capitals. But they certainly limit the scale of their intensive and extensive disbursement on land. In turn, this limitation affects the pace of technical innovation in agriculture and extends the specific national limitations as far as the only sector truly able to compete on the world market. As such, only those industrial capitals which produce on a scale already superseded by the development of the productivity of labour on a global scale, are able to valorise themselves in Argentina. Some of them fit into this category because they are just small capitals. Others do so because they are specifically restricted fragments of capitals that actually operate on a normal scale elsewhere. The former are unable to develop the productive forces of society owing to their limited size. The latter obtain a normal rate of profit, and may even make extraordinary profits, without fulfilling their historical role in that selfsame process of development. Moreover, they are actually freed from the costs of developing the productive forces as they are able to convert what has already become scrap in the countries where capital operates on a normal scale into brand new capital in Argentina. Hence, although the Argentine national process of accumulation appears to be an ordinary national process of development of the productive forces of society, it is in fact working against this development.

This contradiction, which is so characteristic of the Argentine economy, acquires a particular shape in the process of capital centralisation. The centralisation of capital tends to liquidate small capitals, therefore undermining one of the sources of additional surplus-value appropriated by concentrated capitals. At the same time, despite the internal concentration and centralisation of capital, the gap between the limited productivity of labour that corresponds to the size of the internal market vis-à-vis the size of the world market, continues to grow. In turn, the privatisation of state enterprises restricts the role of the state as a source of demand to sustain the internal market, adding new capitals that demand their share of ground rent, of the value of labour-power and of the surplus-value freed up by the small capitals.

---

[35] Iñigo Carrera 2002, pp. 12–14; see the methodological criteria on pp. 5–9, and the data table on p. 32, based on original information from BCRA, INDEC and BLS.

But there was another element which pushed the contradiction inherent in the Argentine process of capital accumulation to a critical point. During the first half of the 1970s, agricultural ground rent rose abruptly. Thus, in each year between 1972 and 1976, industrial capitals appropriated eight times the real average annual amount they had appropriated in the 1960–71 period.[36] Yet, after reaching this peak, world ground rent began to drop in a downward trend that has continued up until the present.

With differential ground rent decreasing and the amount needed to support accumulation in fragmented industrial capitals rising, the Argentine process of capital accumulation increasingly witnessed the deterioration of its specific basis. The value product fell into stagnation and decline, whereupon the profit freed up by small capitals shrank even more and the gap between the scales of the domestic and the world market widened. Moreover, the consequent multiplication of the surplus-labouring population enabled capital to pay labour-power below its value, which counterbalanced the former effects, thereby providing a new basis for the reproduction of the specific nature of the national process of capital accumulation.

As the national economy stagnated and shrank, the overvaluation of the currency not only served as a mediator in the appropriation of ground rent but also narrowed the gap in productivity inherent to the relatively restricted scale of production for the internal market. It did so directly by enabling the cheap import of means of production and indirectly by allowing the import of cheapened means of subsistence for the workers, thus cheapening their labour-power. Additionally, lower import duties reinforced the effect of the overvaluation of currency. However, at the same time as cheapened imports displaced local production, the reproduction of the national process of capital accumulation on the basis of an overvalued currency and free-trade policies came ever closer to death by suffocation.

---

[36] Iñigo Carrera 2000, pp. 62–3.

Ten years of a highly overvalued currency required a significant accumulation of reserves in foreign currency. However, a national economy whose size in terms of value was shrinking, whose reproduction demanded the growth of imports over exports, and which was suffering from the contraction of ground rent, had no means of generating such reserves on its own. Where did these reserves come from? The answer lies in the real expansion of foreign public debt.

There exists the widespread belief that the payment of the foreign public debt resulted in the continuous outflow of social wealth which was ultimately responsible for the collapse of the Argentine economy. Despite its apparently critical slant, this belief clashes with a simple fact: from the 1960s onwards, Argentina received a continuous influx of social wealth as a result of increasing its debt in real terms over the capital and interest payments that were due.[37] These additional funds, together with those raised through the privatisation of enterprises owned by the state, provided the reserves that sustained the overvalued national currency. However, the very same overvalued peso acted as a stimulus for the expatriation of foreign currency by the private sector. So, as soon as the national state topped up its reserves by increasing its foreign debt, the private sector drained them by sending foreign currency abroad. This locked the state into a constant vicious circle of increased public indebtedness created in order to maintain the overvalued peso.

This cycle was rooted in the overabundance of fictitious capital circulating in the world market. During the last quarter of the twentieth century, global capital accumulation entered one of its phases towards general overproduction.[38] Overproduced capital started to circulate as fictitious capital, namely, as a mass of credits conceded to insolvent debtors that merely keep up the appearance of valorisation by constantly accruing due interests to an unpaid and overdue principal. As the advance of the global economy towards general overproduction maintained the appearance of being a mere process of accumulation based on the expansion of credit, the Argentine state was able to expand the influx of foreign currency to replenish its reserves. But, in 2001, general overproduction manifested itself to such a degree that it abruptly put the brakes on the global expansion of fictitious capital. At the same time, the expanded access to global fictitious capital was subject to the capacity of the

---

[37] For a computation of these movements see Iñigo Carrera 2002, pp. 24–9, and the data table on 36–7, based on original information from BCRA, ME, INDEC and BLS.

[38] Iñigo Carrera 2003, pp. 67–75.

Argentine economy to maintain the appearance that it was able to honour its debt. The same overvaluation of the national currency, the expansion of imports, the privatisation of state enterprises, and so on, helped to support this fiction. But, here too, reality was eventually due to burst in. Those state assets suitable for immediate privatisation had been exhausted and the national process of capital accumulation openly clashed with its specific limit, therein contracting the value of GDP and brutally increasing unemployment. The same contradiction between economic contraction and the unstoppable expansion of foreign debt made interest rates soar.

Together, the global crisis and the Argentine crisis – the latter became intensified as a specific expression of the former – brought the cycle of replenishment of foreign currency reserves through ever increasing levels of foreign indebtedness to a violent end. The across-the-board renewal of due debts (the plans of 'Blindaje' and 'Megacanje') threw the painful nature of this process into sharp relief. Then, as it became evident that no new real expansions of the state's foreign debt were at hand, the private depletion of the reserves accelerated, showing that 'convertibility' and its overvalued currency were about to collapse. Although bank deposits were nominated in US dollars and supposedly guaranteed by the strongest international banking capitals, these turned out to be equally unsustainable fictions: as soon as the withdrawal of deposits (to turn them into true US dollars) accelerated, the same neoliberal banking capitals clamoured for state intervention. And the state obeyed by introducing the *corralito*, enclosing bank deposits.

The unstoppable crisis reached into every nook and cranny of the Argentine economy. Credit disappeared, tax collection fell to rock-bottom levels, bankruptcies and factory closedowns multiplied, and unemployment peaked. A substantial devaluation of the peso was imminent. A devaluation of this kind meant a further fall in real wages, rises in costs and unbearable losses in an economy where most domestic liabilities and contracts were denominated in foreign currencies.

The national process of capital accumulation was heading for a situation involving a substantial fall in real wages, a violent contraction of its scale and an open default on its foreign debt. At this point, the issue was the political form that the crisis was to take.

The political representation of capital accumulation in Argentina

At the turn of the twentieth century, the agricultural landowner class dominated the general political representation of the national process of capital accumulation. Nevertheless, as industrial capitals became stronger partners in the appropriation of ground rent, landowners were relegated to a secondary position.

Argentina's development as a space for the accumulation of capitals that, despite their normal global scale, operate as limited fragments to be valorised in the specific way detailed above, was dependent on an existing specific condition. It required the wide-scale presence of genuine small capitals. This was a condition that both provided the domestic market with sufficient breadth and endowed fragmented capitals with one of the sources of additional surplus-value which they required to compensate for their own limited scale. Hence, in its historical development, Argentine capital accumulation went through a phase characterised by the general transformation of ground rent into a mass of small domestic capitals. This multiplication of small capitals not only absorbed the already active labouring population but also multiplied it on a wide scale so that it appeared to be the very cradle of the Argentine working class. On this basis, the Argentine petty bourgeoisie and the working class converged in the general political movement that consolidated the genesis of the specific form of the national process of capital accumulation in the 1940s; namely, Peronist populism.

From this point on, the immediate reproduction of the Argentine working class as an active labouring population and of the national petty bourgeoisie remained tied to the reproduction of this specific form. This reproduction gave way to the widespread arrivals of the particularly restricted fragments of normal capitals, starting in the 1950s. Given their foreign origin, these capitals could not be politically represented in Argentina by their own bourgeoisie. Nevertheless, since their accumulation had become a condition for the reproduction of the national economy, they were able to delegate their political representation within the same populist movement and also through the diplomatic staff of their countries of origin. So-called developmentalism [*Desarrollismo*] was the most genuine expression of this political representation. Furthermore, throughout Argentine history, the appropriation of ground rent has been mediated by the actions of the national state as the general political representative of the total social capital that is valorised in the country. Hence the specific participation of the state bureaucracy, particularly the armed forces, in political struggles. When the national accumulation of capital entered a phase of growth based on a circumstantial increase of ground rent, its general political representation corresponded to a populist-democratic government. When the economy contracted, however, this place was taken by a military dictatorship actively supported by foreign capitals.

As a product of the specific form of the national process of capital accumulation, the Argentine left-wing parties could not escape being determined as particular political representatives of the reproduction of the selfsame specificity.

Yet they were unfit to act as the general representatives of the working class within this process, as this role corresponded to the populists. The role of left-wing parties was restricted to spearheading the struggle for higher wages and the reinstatement of democratic government when the economy entered expansive phases. On the surface, it seemed that these struggles brought into question the overthrow of capitalist society itself. Yet, as economic expansion began to consolidate itself, the left-wing parties found themselves ousted by mere populism. And, as soon as the subsequent process of contraction got under way, their struggles against falling wages and rising unemployment – vis-à-vis the retreat of the populists – turned them into scapegoats, suffering the wrath of a new military dictatorship. Even those parties that called for a revolutionary expropriation of the bourgeoisie were unable to overcome the appearances of the Argentine specificity. Therefore, they completely overlooked the specific nature of the very material base on which that expropriation would have had to operate. In Argentina, the bourgeoisie had set up nothing but a mass of obsolete means of production materially unfit to support the development of the productive forces of society.

In fact, over twenty-five years ago, the fluctuation between expansive and contracting phases gave way to a blatant tendency towards stagnation and decline in the political form of the bloodiest military dictatorship. The dictatorship imposed itself when the circumstantial expansion of the national process of capital accumulation – largely due to the exceptional increase of ground rent during the years 1973–4 – came to an end. And it did so by bringing about the armed defeat of the political forces that had welcomed the same circumstantial expansion of Argentine capital accumulation as evidence that this process would lead directly towards socialist supremacy. From then on, the reproduction of the Argentine economic specific form resulted in the accelerated liquidation of the petty bourgeoisie and an increasing transformation of the working class into a surplus population for capital.

Nevertheless, even going downhill, the immediate reproduction of both social classes remained tied to the reproduction of the specific nature of the national process of capital accumulation.

The coalition between the petty bourgeoisie and the working class continued to bear the general political representation of Argentine capital accumulation. However, intermittent periods of expansion increasingly proved unable to counteract the overall trend of contraction. Expansionary phases became weaker and weaker, whilst the surplus-labouring population continued to grow even through these phases. There was no place left for the generalised illusion concerning the political powers gained by the working class and the petty bourgeoisie during the expansionary phases that needed to be annihilated when renewed contraction became apparent. Thus, even as the crisis deepened, democracy acquired continuity. This process of accumulation, which only could reproduce the petty bourgeoisie and the working class at the expense of their accelerated liquidation to the benefit of the most concentrated capitals, acquired its proper political shape through populist rhetoric with neoliberal content.

In 1976, only a bloody military dictatorship that systematically abducted shop stewards from their workplace and made them 'disappear', was able to reduce real wages by 35%. Then, throughout the 1990s, real wages dropped even more sharply, to an average of 40% below the levels reached between the years 1973–5.[39] But, in this case, it was not a military dictatorship but the Peronist government of the Justicialista Party that was in office. The same low levels were sustained under another democratic government with a populist programme and a neoliberal policy, namely, the Alianza Party headed by De La Rúa, which was the opposition to the Justicialistas. These facts are clear indicators of the significant weakness suffered by the political and union strength of the Argentine working class during the last quarter of the twentieth century.

Nevertheless, by the end of 2001, the inevitable devaluation was set to cause a drop in real wages of such proportions that the situation, coupled with a drastic rise in unemployment, could only be handled by a government able to ensure the absolute paralysis of the unions. Only the Justicialista Party enjoyed such a capacity, supported by both the official federation of unions (CGT) and the strongest dissident federation (MTA). At the same time, the Alianza government found itself unable to declare default on the external debt, since it had claimed repeatedly that payments to foreign creditors were guaranteed and that 'convertibility' was to be maintained whatever the consequences. In fact, devaluation and the default would need to acquire the political form of a statement of national autonomy if they were to push through. Once more, Peronist populism was their appropriate political expression. However, the Alianza government was just in the middle of its term in office. Therefore, if the Justicialista Party was to take power, President De La Rúa would have to fall. All the conditions pointed towards a 'democratic' overthrow, in other words, towards the fall of the Alianza government at the hands of its own social base: the petty bourgeoisie and the working class that performs complex labour.

---

[39] Iñigo Carrera 2002, p. 20.

In 1989, the widespread looting set the scene for the premature transfer of power from Alfonsín, of the Radical Party which had become the basis of the Alianza, to Menem, of the Justicialista Party. In 2001, the looting acted as the spark that revealed the government's impotence in handling the situation. On 19 December, rumours about looters moving in on shops and homes in the more prosperous neighbourhoods were spread intentionally among the population. Everybody remained alert. Even in the financial district, shops closed early and boarded up. In the outer areas, neighbours prepared themselves for a night of surveillance and formed bands of vigilantes. The president declared a state of siege and offered up the head of his minister, Cavallo. But he insisted on remaining in power. In this tinderbox-like situation, the spark ignited the explosion: the *cacerolazos* of the petty bourgeoisie and the skilled workers, followed by the march on the Plaza de Mayo. Powerless, the government brutally turned on its own social base while President De La Rúa fled to the sound of the cries of 'all of them must go!'.

Nevertheless, not all of them left. Immediately after the government had fallen, and with the Alianza's agreement, the Peronist majority at Congress appointed Rodríguez Saá as the new president. Rodríguez Saá appeared as the reincarnation of populist nationalism. He declared the default on the foreign debt, something acclaimed as a nationalist victory by those very same representatives that supported each of Menem's neoliberal policies. Yet, at the same time, Rodríguez Saá's populist rhetoric appeared to run too close to that of the unions. Furthermore, once the default had been declared, the time came to reproduce the national process of capital accumulation through new agreements with the IMF and a dramatic drop in real wages. Just one week later, the Justicialista Party withdrew support for Rodríguez Saá, while his alliance with the union bureaucrats and the appointment of a former mayor of Buenos Aires City who was emblematic of political corruption were enough to warrant another *cacerolazo*. Again, the petty bourgeoisie and the skilled working class banged their pots and pans. Rodríguez Saá was forced to abandon office. The Congress appointed Duhalde as president – the same man in command of the Peronist apparatus in the Greater Buenos Aires region – a group, let us not forget, which had been quite active in the looting.

With the default already declared and the devaluation of the peso as an unavoidable condition for the banking system to start operating again after more than fifteen days, Duhalde was ready to devalue and to relaunch negotiations with the IMF. Thus, the declaration of default, the drop in real wages and the further contraction of the economy, had developed their political form. By May 2002, real industrial wages had fallen by 24%.[40] The national rates of unemployment and underemployment soared to 21.5% and 18.6%, respectively.[41] However, the CGT and the MTA supported the government and remained inactive. The CTA carried out protests but with no practical results. For the second quarter of 2002, the GDP had fallen by 13.5% compared to the year before.[42] The situation in the City of Buenos Aires had become significantly worse:

Table 2
Unemployment and poverty in the Greater Buenos Aires, May 2002[43]

	Population (millions)	**% of the economically active population**		**% of total population below the line of:**	
		Unemployed	**Under employed**	**Poverty**	**Extreme poverty**
City of Buenos Aires	3.0	16.3	15.6	19.8	6.3
First Belt of the Great Buenos Aires	3.0	21.9	18.3	41.5	16.8
Second Belt of the Great Buenos Aires	6.7	25.6	21.9	66.6	33.2

Nevertheless, no more looting occurred. The national process of capital accumulation had reproduced itself once again upon its specific base.

What crisis of political representation?

The specific modality of capital accumulation in Argentina could only be reproduced through a profound crisis, a kind of crisis which would take concrete shape as a legitimacy crisis of formal political representation.

In the capitalist mode of production, the general social relation – social power – exists as a thing carried in one's pocket (that is, money).[44] On this basis, political corruption is inherent to capitalist accumulation. But, when accumulation is specifically based on the appropriation of ground rent through the political mediation of the state for the benefit of capitals operating on restricted scales, political corruption is placed at its very core. Moreover, the exhibition of illegally obtained wealth becomes a demonstration of social power. The more the national process of capital accumulation clashes against its specific limit, the more crucial the role played by the shameless exercise of corrupt political representation becomes.

The legitimacy crisis of political representation did not emerge from the public discovery of the specific limits inherent to the national process of capital accumulation. On the contrary, it emerged from the apparent non-existence of such specific limits, whereby the economic crisis resulted from the inability of political representatives to reproduce the former situation of the petty bourgeoisie and the working class. In turn, their ineffectiveness was attributed to their systematic plundering of social wealth to the benefit of more concentrated capitals as well as themselves.

In brief, the crisis of political representation did not entail any greater levels of awareness than the demand for the reproduction of the specificity of the Argentine economy but without the inescapable consequences of such reproduction. The impotence expressed by this demand was the real essence contained in 'out with them all' as the key proposal for political action to face the crisis.

The abyss that lies between the appearance and the content of 'all of them must go!' questions Dinerstein's claim that:

---

[44] Marx 1993, p. 157.

> *[¡Q]ue se vayan todos!* is qualitatively significant as it constitutes the initial 'adequate idea' that, as Deleuze suggests with reference to Spinoza, puts people 'in possession of their power of understanding, and so by our power of action'[45]

On the contrary, based on the inability to discern beyond immediate appearances, *¡Qué se vayan todos!* actually reveals one's inablity to seize power with one's own hands.

Realities of 'all of them must go!'

Dinerstein asserts that 'after December 2001 something (everything) has definitely changed' in Argentina.[46] Let us consider what she presents as the core manifestation of the new 'non-identity, horizontal, democratic and anti-institution politics and the reinvention of the political which began in December 2001'[47] able to overcome the capitalist mode of production: the neighbourhood assemblies.

By October 2002, 119 neighbourhood assemblies existed in the City of Buenos Aires and 62 in the Greater Buenos Aires region.[48] Therefore, each one corresponded to an average population of 25,000 and 156,000 respectively. At that time, the neighbourhood assemblies played a significant role in the rapid succession of governments that gave political shape to the reproduction of the national specificity of capital accumulation, each of them drawing several hundreds of people at best.[49] Nowadays, the few surviving assemblies congregate one or two dozen people, perhaps as many as thirty participants (many of whom are activists from the traditional left-wing parties). Nevertheless, when the time comes, the assemblies do not hesitate to speak in the name of the immense majority of their absent neighbours. The so-called 'inorganic horizontal organisation' has no other content than the absolute centralisation of the decision-making process by those who control the assemblies. Thus, while some assemblies voted to exclude anyone who was affiliated to a political party, others are directly controlled by this or that party.

[46] Dinerstein 2002, p. 23.

[47] Dinerstein 2002, p. 26.

[48] Galvani, Levy and Gringauz 2002, p. 10.

[49] Only the meetings of the inter-neighbourhoods assemblies surpassed the thousand participants during their first few months of existence.

Some assemblies voted for resolutions against the IMF, the nationalisation of the privatised companies, but, in practical terms, their achievements come down to some minor urban improvements and cultural activities. They also provide some food and clothes to the impoverished. Clearly, these activities satisfy real needs, given the current situation, but they have nothing to do with the overthrow of the capitalist mode of production, however charitable they might be. Moreover, as soon as the same activities became systematic, they started to show all the marks of political clientelism and charitable relationships.

The roadblocks of the organised unemployed [*piqueteros*] were decisive for the implementation of extended unemployment subsidies, which reached almost two million people and have been effective since 2002. The killing of two of their activists by the police under Duhalde's administration forced him to bring the 2003 elections forward. Today, the *piqueteros* retain their capacity for mobilisation. Nevertheless, their power to transform the current social conditions has not gone beyond that immediately emerging from the reproduction of unemployment itself: the struggle for subsidies (which fall short of the limit of extreme poverty), community kitchens and orchards, complementary schooling, some very small-scale production, health care, and so on. Certainly, these actions are the concrete forms through which a part of the Argentine surplus population is still able to survive. At the same time, they place a barrier to further falls in the wages of the employed workers, which, in turn, means that they place a barrier on the possibility of capital accumulation further freeing itself from the need of technological development. However, there is an abyss between these potentialities and that needed to support the claim about a 'new identity' able to overcome the capitalist mode of production. Moreover, as Dinerstein herself points out, most of the unemployed organisations are related to traditional left-wing parties; for example, the Corriente Clasista y Combativa (Maoists), the Polo Obrero and the Movimiento Teresa Vive (Trotskyists), the Movimiento Territorial de Liberación (Communist Party) and the Barrios de Pie (left-wing populist nationalism). The Federación de Tierra y Vivienda, that claims to be the largest organisation, openly supports Kirchner's administration and its chief leader has been elected to Congress. The Movimiento de Trabajadores Desocupados Aníbal Verón, commonly taken as an example of the powers that emerge from political independence and horizontal organisation, has been plagued by internal power struggles and went through successive splits. Besides, the *piqueteros* organisations are based on the management of the assistance plans for the unemployed, holding a total share of about seven per cent.[50] The rest of the plans are managed through structures of political clientelism. Under such conditions, clientelism permeates the *piqueteros* movement, a fact pointed out by the organisations themselves as they exchange accusations.

The barter clubs disappeared in the midst of the scandalous theft perpetrated against their members through the issue of token 'money'. In turn, as with any private capital, those factories turned into co-operatives by their workers can only survive if they are competitively successful. Within a national economy the scale of which is subject to contraction, successful competition means expelling other capital enterprises from production. Therefore, co-operative success means that other workers may lose the chance to sell their labour-power. Under capitalism, solidarity is merely the necessary concrete form taken by the basic social relation existing between the owners of commodities: competition. The illusions about market socialism could be nothing more than that: illusions to be swept away by the realities of the commodity-form.

Let us take another example: the Autodeterminación y Libertad party, which lays claim to horizontal organisation and anti-institutionalism, praises Negri and Holloway, and has '*¡qué se vayan todos!*' as its main slogan. Zamora, its leader, was one of the candidates with the highest voter-intention support (no more than 10–15%, however) for the 2003 presidential elections. The moment came to decide if he was to stand as a candidate. Since no formal organisational structure existed, everybody was free to present his or her point of view; but the final decision remained the undisputed privilege of the leader. Zamora chose to abstain. Those in Autodeterminación y Libertad who were for taking part in the election were left with no opportunity to do so: such a horizontal movement had one, and only one, popular figurehead: Zamora. Only alienated consciousness fits with the capitalist mode of production, and the more it attempts to present itself as abstractly free, the more alienated it becomes.

Let us now take a look at the other face of the powers inherent in *¡qué se vayan todos!* Santiago del Estero is one of Argentina's poorest provinces. In 1995, a local popular protest, the *Santiagazo*, made it into the history books for two reasons. On the one hand, it was the first widespread revolt against the consequences of Menem's neoliberal policies and political corruption.

---

[50] Calvo and Guagnini 2004, p. 28.

On the other, the protesters set fire to the house of the former governor Juárez. Juárez was the almighty leader of local Peronism and a symbol of authoritarianism and corruption. In September 2002, Juárez imposed his political heir as governor and his wife as vice-governor with 68% of the votes,[51] presenting this victory as proof that in fact the popular will was 'all of them must stay!'.[52]

Both in 1989 and 1995, Menem was elected president by 50% of the votes. The first time, he won with a populist discourse and only afterwards did he practise neoliberal policies. The second time, he won with his well-known neoliberal precedents and discourse. In the 2003 presidential elections, Menem won the first round. During his campaign, he had reasserted his neoliberal discourse and advocated army intervention to quell social unrest. Subsequently, he withdrew from the second round as it was evident that he was going to be defeated by Nestor Kirchner, a more 'traditional' populist Peronist supported by Duhalde. Kirchner has been the Peronist governor of Santa Cruz Province since 1991. What form of capital accumulation does he represent? After the acute contraction of the national process of capital accumulation in 2002, the new phase of expansion without the possibility of receiving fresh funds from foreign creditors is taking a renewed populist shape: the assertion of national sovereignty, a discount on the defaulted foreign debt, import substitution, widespread support for the indigent unemployed, and the like. Of course, the real basis for this lies, firstly, in the further fall of wages below the value of labour-power and, secondly, in a fortunate rise of agricultural and oil ground rent.

The Argentine economy has surged forwards on this renewed basis, growing almost 9% in physical terms both in 2003 and 2004. In so doing, GDP has returned to the level it was in 1999, which was by no means a glorious year but the starting point of the previous contraction and crisis. Yet, Kirchner enjoys high rates of popularity after a year and a half in office.[53] Now, Kirchner has asked the Peronist unions to take to the streets in order to stop the more combative *piqueteros*.

---

[51] *Clarín* 2002a, p. 10.

[52] Braslavski 2002, p. 18.

[53] By January 2005 he had a 78% of positive image, according to the Centro de Estudios de Opinión Pública (CEOP), while his administration had a 64% of positive image, according to the same source, and a 51% according to Universidad Torcuato Di Tella/Catterberg y Asociados. See *Clarín* 2005, p. 12, and *La Nación* 2005, p. 6.

The 'progressive' alternative who had a chance for electoral success in 2003 was Elisa Carrió, from the ARI. She is a Catholic fundamentalist who broke off her alliance with the Socialist Party as soon as they proposed the – extremely limited – framework for the legalisation of abortion. Notwithstanding, she finished fourth in the first round, behind her ultra-neoliberal former party colleague López Murphy.

Dinerstein presents spoiled ballots as yet another manifestation of a supposedly popular advance beyond representative democracy.[54] Spoiled ballots fell from their 20% peak in the 2001 elections, to 1.6% in 2003 elections. Meanwhile, electoral absenteeism only rose 2.5% between the 1999 and 2003 presidential elections.[55] It has become commonplace to pinpoint electoral absenteeism and spoiled ballots as a means of protest against the lack of legitimate political representation [*voto bronca*]. But it includes a high component of political impotence rather than active protest and, even, of political indifference. Besides, a part of the vote that repudiates political representation points in an opposite direction to pro-democratisation illusions.[56] The point is not about an abstract 'against power' but about a concrete 'for whose power'.

It is clear that, since December 2001, many things have changed in Argentina. But these changes express the reproduction of the national process of capital accumulation in its specific form. This means that they express the specific limits to the latter process and the widespread transformation of the Argentine working class into a labouring surplus-population for capital. Essentially, everything has changed so that everything can remain the same.

Capital

Thus far, it could seem that the very different conclusions to which Dinerstein and I arrive emerge from our differing approaches to Argentine capital accumulation. Nevertheless, our differences have much deeper roots, resulting from looking at capital itself from contrasting points of view.

Dinerstein supports a theory that is currently much in vogue among many critics of capitalism. This theory asserts that the capitalist mode of production still exists because it is able to impose a social relation of domination over social subjects, forcing them to reproduce their lives through the mediation of abstract labour:

---

[54] Dinerstein 2002, p. 25.

[55] Calvo 2003, p. 12. Voting is legally compulsory for all citizens in Argentina.

[56] 'Anger voting . . . is more observed among the upper class and the upper middle class.' Ricardo Rouvier & Asociados, in *Clarín* 2002b, p. 8.

> Capital is not an external force but a social relation, which can only be maintained by forcing human practice to exist and be recognised through abstract labour (i.e., money).[57]

Thus, capital is not recognised as the general social relation that determines the social being of social subjects by itself. It is seen as a social relation imposed on a social being of the social subjects that stands beyond capital. Does it stand on an abstract 'human nature', perhaps?

From this point of view, the state and the law represent several forms of this imposition:

> As the most abstract form of capital, money, like the state and the law, mediates the creation of determinate social subjects (e.g., the unemployed, the poor, a citizen with savings in a bank account).[58]

Thus, capital's actual reason for existence is brought down to the mediation of the 'logic' that capital forces upon a supposed abstractly free determination of social subjects. In this line, any confrontation with established power appears as carrying within itself the self-affirmation of an abstractly free subjectivity over the subordination to capitalist mediation:

> The insurrection was experienced primarily as a moment of self-possession, a moment in which fear and frustration were transformed into a collective action against power. . . . The popular insurrection of December 2001 is better understood as a human limit on the violence of capitalist anarchy in Argentina. . . . The power affirmed in December 2001 in the streets of Buenos Aires was, in fact, a negative power. The mobilising force of the insurrection was not the identity or the organisation that people join or the type of demands they put forwards, but what I would like to call the *unrealised*. The unrealised is *what we are not*. It is critique. It consists of a universe of needs, ideas, practices, experiences, desires, frustrations, dreams that were postponed and repressed. The unrealised is the undefined, that which cannot be, or exist, or be done or accomplished, that which cannot be developed or realised, that which cannot be explained but felt . . .[59]

---

[57] Dinerstein 2002, p. 25.
[58] Ibid.
[59] Dinerstein 2002, pp. 23–4.

In this manner:

> The streets have become the place for both the rejection of the subordination of social reproduction to the logic of capital and the reinvention of politics.[60]

However, it is worth querying the precise nature of the 'reinvention of politics' that Dinerstein offers us. It is one in which the 'power of understanding' has collapsed into 'that which cannot be explained but felt'. Rationality has given way to the exaltation of irrationality. Every revolutionary determination of the working class has come down to Holloway's 'scream'.[61]

A world made of 'that which cannot be, or exist, or be done or accomplished, that which cannot be developed or realised' is a world made of many ideal constructions: chimeras, utopias, faith. But scientific consciousness has no place in it. Science only deals with real concrete existence, in its unity both as an actuality and as a potentiality.

Marx discovered that the capitalist mode of production embodies the necessity to supersede itself into a society of freely – that is, consciously – associated individuals. He discovered that the conscious revolutionary action of the working class is the necessary concrete form of this overcoming. Since then, capitalist ideology has placed objective rationality under constant attack. Of course, philosophy is the natural field to cultivate irrationality. But epistemology has developed into an autonomous field based on the assertion that scientific knowledge necessarily stops at appearances. Thus, the idea that objective knowledge is just another way of interpreting the world has acquired the strength of a prejudice.[62]

Shaped as a utopian critique of capitalism, Dinerstein presents us with yet another fashionable attempt to excise working-class revolutionary action from its necessary base in objective knowledge.

In the world of the 'unrealised', desires, ideas, dreams and other ghosts emerging from some abstract human spirit reign over the social being of the working class.[63] Let us return from such a fantastic world to the concrete realisation of this social being. Let us look, thus, at the economic formation of society as a process of natural history.[64] Human natural history is the history of the transformation of the material conditions of social life through labour. The development of the human being as a historical subject is but the development of the human capacity to act in a conscious and voluntary way upon the rest of nature, in order to transform it into a means for human life. In other words, the development of the human being as a historical subject is the development of the human condition as the subject of production, in other words, of human productive subjectivity. This development is the only materialistic concrete starting point, and therefore the only scientific one[65] in order to produce consciousness concerning any historical process.

---

[60] Dinerstein 2002, p. 31.

[61] Holloway 2002a, p. 1.

[62] Iñigo Carrera 2003, pp. 211–23.

[63] Actually, this abstract human spirit reflects the appearance that emerges from circulation. In circulation, alienated consciousness presents itself under the shape of its opposite, free consciousness. That is why ideology always sticks to this appearance.

The capitalist mode of production begins by dissolving all general direct organisation of social labour based on relations of personal dependence, thus turning producers into free individuals. In this way, it gives each concrete portion of social labour the specific form of private labour performed independently from the rest. Then, total social labour-power is allocated into its useful concrete forms through an autonomous system. As it is performed in a private and independent way,[66] the abstract socially necessary labour – a simple productive expenditure of the human body in whatever concrete form it is made[67] and, as such, a natural condition for human life, independent of the social modality it is ruled by[68] – acquires an historically specific social form. After it has been materialised in its products, it appears represented as the aptitude of these products to relate to each other in exchange, thus placing their private and independent producers into a social relation.[69] In other words, materialised privately-performed socially necessary abstract labour is represented as the value that determines use-values as commodities.[70]

Since they need to produce their general social relation through material production, the free individual consciousness and will of the producers that privately and independently organise their social labour are both subject to a historically specific determination. They must submit themselves to the necessities imposed on them by the value-form of their own material product. They must act as personifications of their commodity; they must produce value come what may, as a matter of life or death. Commodity producers are free from any personal servitude because they are the servants of the social powers of their products. While the will of the producers completely dominates the private and independent exercise of individual labour, these same producers are in turn completely subordinated to the social powers of the material product of that self same labour. From the point of view of the participation of private and independent producers in social labour, their consciousness and will matter only inasmuch as these personify the powers of their commodities. The productive power of their social labour confronts the producers themselves as an alienated power, as a power incarnated in their commodities. The free consciousness and will of commodity producers is the concrete form in which their alienated consciousness and will exist.

---

[64] Marx 1965, p. 10.
[65] Marx 1965, p. 373.
[66] Marx 1965, p. 42.
[67] Marx 1965, pp. 38, 44 and 46.
[68] Marx 1965, p. 71.
[69] Marx 1965, pp. 72–4.
[70] Marx 1965, p. 38.

Therefore, social production is not immediately aimed at producing use-values, but at producing the general social relation itself, that is, value. And the production of value reaches its complete development as a production of value starting from substantive value itself, in other words, the production of surplus-value. The material product of social labour that bears the general social relation thus becomes itself the subject of social production and consumption, namely, capital.

As free independent individuals, wage-labourers enter their general social relation as personifications of their only sellable commodity, their labour-power. Hence, the working class has nowhere from which to obtain any historically specific revolutionary powers other than those it gets from its own general social relation, namely, the production of surplus-value. Strictly considered, the history of the production of surplus-value is nothing but the history of the production of the material revolutionary powers of the working class and, therefore, of its revolutionary consciousness and will.[71]

Nevertheless, it is not just about the development of the formal subsumption of labour to capital, as it could appear when the determinations of class struggle are inverted. Through the production of relative surplus labour, labour becomes really subsumed in capital.[72] Even in the very process of individual consumption and in their determination as a working class, the workers become an attribute of capital.[73] Thus, capital produces and reproduces them as human beings, that is, as bearers of consciousness.[74] This happens to the point that capital even rules the laws of their biological reproduction.[75] In the circulation of commodities, the consciousness of the labourers appears as free. However, the consciousness and will of the labourers are actually determined as the necessary concrete forms taken by the alienation of labour's powers as capital's powers, namely, their own objectified general social relation that has become the alienated concrete subject of social life.

---

[71] 'It is not a question of what this or that proletarian, or even the whole proletariat, at the moment *regards* as its aim. It is a question of *what the proletariat is*, and what, in accordance with this *being*, it will historically be compelled to do'. Marx 1975, p. 37.

[72] Marx 1965, pp. 509–10.

In pursuit of relative surplus-value, capital constantly revolutionises the material conditions of production. So much so that, in developing the machinery-system, it revolutionises the very nature of labour. Essentially, labour ceases to consist of the exertion of human labour-power upon its object in order to effect its transformation. In contrast, it centres on the application of human labour-power to the scientific control of natural forces and to the objectification of this control as an attribute of machinery, so as to make those natural forces act automatically upon the object in order to transform it.[76] Consequently, commodity producers are collective individuals – formed by doubly-free workers, both in the sense of not being submitted to anyone's personal domination and of being separated from the means of production needed to produce their life on their own account – that perform their labours in a private and independent way. As independent private producers, these collective producers possess complete dominion over their individual labour processes, but lack all control over the latter's general social character. Therefore, they must submit their consciousness and will as collectives formed by free individuals to the dominion of the social powers of the material product of their labours, capital: they must produce surplus-value. The free consciousness and will of the members of the collective labourers are the concrete forms of their consciousness alienated in capital.[77]

The transformation of labour and of commodity producers makes evident the historical reason for the existence of the capitalist mode of production: the transformation of the productive powers of free individual labour into the productive powers of collective labour consciously organised by the same collective labourer that performs it, under the contradictory form of the socialisation of private labour.[78] This contradictory socialisation necessarily takes on a concrete form through the centralisation of capital. The revolutionary action of the working class is the necessary concrete form in which the above-mentioned constant revolution in the materiality of labour – which, at the same time, entails their direct socialisation – develops its need to be organised as a directly social power that transcends the limits of its private capitalist form. Therefore, this revolutionary action is the necessary concrete form in which the capitalist mode of production fulfills its historical necessity to supersede itself through its own development, thus engendering the general conscious organisation of social life.

---

[73] Marx 1965, p. 573.
[74] Marx 1965, p. 578.
[75] Marx 1965, p. 643.
[76] Iñigo Carrera 2003, p. 11.
[77] Iñigo Carrera 2003, p. 13.

This process does not flow through the abstract possibility of the working class turning its back on its own social being and the revolutionary powers it bears, in the name of the abstract freedom inherent to circulation. On the contrary, it flows through the working class taking its alienated general social relation into its own hands, in other words, appropriating social capital. This appropriation implies the centralisation of capital as state property[79] and obviously points towards the absolute socialisation of private labour through the formation of a global state.

The currently fashionable ideological rejection of seizing state power, that is, of seizing the power of the general political representatives of social capital, does not express the power of a social movement in order to overthrow capitalism. On the contrary, it expresses its *impotence* to do so.[80] The centralisation of capital through the political action of the working class is certainly not the path of carnivals and 'explosions of the principle of pleasure' offered by Holloway.[81] Likewise, it is not the path of innocence, simplicity and love offered by Hardt and Negri.[82] In contrast, as it is inherent to the development of human freedom through the development of alienation, it is a path that runs through the gamut of misery, suffering and bloodshed that capital imposes on the working class. Yet, it is the only path opened for the working class to overcome itself by superseding the capitalist mode of production.

The historical powers of the Argentine working class

Contrary to the generic historical power of the capitalist mode of production, capital accumulation in Argentina has developed on the basis of the absence of capital concentrated on a scale necessary to partake actively in the development of society's productive forces. Argentina has received an extraordinary influx of social wealth in the form of differential agricultural ground rent. Still, instead of transforming this mass of wealth into capital concentrated on a scale able to develop the productive forces, Argentine capitalism has spoiled it by feeding capitals whose mere existence comprises a retreat from that development. In the first place, it has fed small capitals that are incapable of stimulating normal levels of labour productivity owing to their restricted scale. Secondly, it has fed capitals bearing a normal global scale but that fragment themselves as small capitals for the purposes of operating in Argentina. Thus, they have freed these capitals from the inherent necessity to develop labour productivity in order to valorise themselves. Therefore, such spoilage of social wealth has meant in itself a retreat from the historical development of society's productive forces inherent to the capitalist mode of production.

The Argentine working class emerged from the specific national form taken by capital accumulation. Hence, the reproduction of this specific form has been a condition for its reproduction as an actively employed working class that is able to maintain its labour-power. This subjection has hindered the Argentine working class from assuming the process of transforming ground rent into concentrated capital. Thus, the specific form taken by capital accumulation in Argentina has not only deprived the national working class of its generic historical powers as the direct personification of the development of society's productive forces; it has, at the same time, closed the concrete path opened to the national working class in order to overcome that deprivation.

The mutilation suffered by the historical powers of the Argentine working class is immediately reflected in the leading role played by the unions within its political organisation. The fulfilment by the working class of its generic powers would have demanded independent political action. That is to say, an action able to impose itself over and above the conditions corresponding to the immediate reproduction of labour-power and, hence, over and above trade-union action. Conversely, the sterilisation of those generic powers has taken concrete shape through the subordination of the independent political action of the working class to its immediate reproduction under the specific form of the national process of capital accumulation. In other words, it has subordinated working class political action to trade-union action.

Nevertheless, the historical powers of capital accumulation provide the Argentine working class with a specific possibility to reverse the present state of affairs, thereby halting its accelerated transition into the labouring surplus population. It is a question of the Argentine working class consciously regaining its generic historical powers by personifying the development of the material productive forces of society. This is not an abstract potentiality, let alone one that arises from the abstract consciousness of the working class. On the contrary, it arises from the consciousness of the Argentine working class being determined as an attribute of capital. Concretely, it is about overcoming the strength that Argentine capital accumulation obtains from freeing itself of its historical role in the development of society's productive forces. It is to be achieved by imposing upon it the overwhelming strength that capital accumulation gains from accomplishing its historical role. A strength that, in the Argentine case, becomes specifically stressed by the magnitude of the extraordinary influx of surplus-value through differential agricultural and energy-sources' ground rent.

The transformation of ground rent into capital able to actively participate in the development of productive forces by acting as a normal productive capital located in Argentina, requires its concentration on a scale necessary in order to compete on the world market. In turn, achieving this scale demands nothing less than the centralisation of capital as a direct social property within Argentina. Therefore, the transformation in question could only take the concrete political form of the abolition of the capitalist and landowner classes within the country. In other words, it could only be performed through a social revolution in which the working class, whose surplus labour would feed the concentrated capital, transforms itself into the collective owner of this capital under the political form of state capital.

By reproducing its specific form, the national process of capital accumulation reproduces only a diminishing part of the Argentine working class as an actively employed working class that is able to reproduce its labour-power. Nowadays, the transformation of ground rent into concentrated capital has become an immediate condition for regaining the normal reproduction of the Argentine working class. Thus, its independent political action has developed a new basis in order to impose itself on union action.

If even the thus-concentrated capital were unable to reach the scale needed to compete on the world market, only one further alternative would remain for the Argentine working class to take part actively in the development of the material productive forces of society. Namely, to integrate its immediate political action with that of the working classes of neighbouring countries in order to form an expanded domestic space for capital accumulation within which the centralisation in question could fit.

Only when the Argentine working class starts to move in these directions will it be truly possible to claim that everything has changed in Argentina.

From Simple Commodities to Capital-Commodities: The Transformation of Values into Prices of Production

Juan Iñigo

The point is not to interpret Marx's texts in different ways but to follow his advance upon the concrete determinations

From the very beginning of his research, Marx pointed out that "the reproduction of the concrete through the path of thought" revolutionarily overcomes the scope of interpretations of reality. By following that procedure, he discovered commodities as the simplest specific form that the general social relation takes in present-day society. Then he advanced by following commodities as they determine one of them as money. He went on following money as it realizes its necessity by transforming itself into capital. And he followed capital through its own development until discovering capital's main historical potency, that is, the necessity of capital to annihilate itself as the concrete form of the general social relation into the community of the freely, - i.e. consciously - associated individuals. On doing so, he got to develop the simplest concrete form in which commodities negate themselves as the simple product of labor, to affirm themselves as the products of labor alienated as a potency of capital. In other words, he got to develop the simplest form in which commodities really determine themselves as capital-commodities and, therefore, the simplest form in which the surplus-value materialized in them develops its concrete form of average profit, thus making their value take its concrete form of price of production. Still, having reached this point, Marx committed what some people regard as a big mistake: he died, so he could not carry his research beyond those simplest forms.

Since then, political economists, mainly Marxist political economists, have focused on these transformations. So the point has taken its well-known form of the "debate about the transformation problem." Did Marx fall into a mathematical mistake when he represented the transformation? Can this mistake be solved without showing the rest of Marx's construction to be invalid? Is it coherent with Marx vision the use of a system of simultaneous equations? Was Marx considering technical relations along with social ones? Was he only trying to achieve a clear representation of exploitation? Was he attempting to provide a proper approximation to the process of price formation? Did he construct a redundant value-system? Did he conceive money in a way that can be considered obsolete today?

Still, the point is not to interpret reality by interpreting Marx in different ways. The point is to change reality. Therefore, the true question at stake concerning the transformation of commodities into capital-commodities is: what is to be done to consciously act upon this transformation, which specifically determines capital as a directly social potency, that is, as total social capital? It is about the concrete form of our conscious action.

The material production that produces the general social relation: commodities as the fetishistic products of social labor

All individual actions are concrete realizations of the process of social metabolism. Therefore, the regulation of this collective process realizes itself as the organic unity of the individual actions. In other words, the regulation of the social metabolism process is the social relation among its members. Under its simplest form, this regulation takes shape as the cognition by each individual (as a moment of his/her own individual metabolism process) of the stage at which the metabolism processes of the other individuals that interact with her/him are, so as to integrate the unfolding of the corresponding part of his/her own metabolism process with them. Human life acquires its own generic being, thus overcoming itself as a specific form of animal life, through the development of its power to transform the environment into a means for itself, to produce its own means of living. As soon as, in this development, the human social metabolism process overcomes the mere coincidence of the undifferentiated individual metabolism processes, that is, as soon as the social division of labor arises, its regulation needs to determine the concrete material form that process is going to take in each of its circuits. Social regulation thus needs to start by allocating the total available capacity for performing productive labor (and, accordingly, for performing consumptive labor) among the different concrete forms this labor needs to take to realize each circuit of the social metabolism process.

The regulation of the human social metabolism process, the general social relation among human beings, has the purely animal immediate cognition as its historical origin. At least according to its length, most of human history up to now has been the history of the transformation of this animal relation into the regulation of social metabolism by means of thought through direct personal relations. In this regulation, the allocation of society's total labor-power into its different concrete forms does not go beyond the control upon them directly as such. Thus, this control is able to develop human material productive forces beyond its own reach as the general form of social regulation. Nevertheless, at the same time, it is unable to develop human cognition so as to make social regulation a collective power of the individuals that cognize, each of them, his/her own determination as a concrete subject of the social metabolism process; that is, a collective power of the freely associated individuals.

The absence of a general coordination through cognition in the allocation and development of social labor determines individuals as private independent producers. Insofar as purely such, they have no way to get into relation by themselves to incarnate the social metabolism process. To begin with, these producers do not retain any social relation other than being individual personifications of society's total power to perform productive labor. This total labor-power is, as such, the capacity for performing human labor in general. The realization of this capacity under the mass of its different concrete forms is, thus, the development of the general social relation among the private independent producers. The materialization of that mass of concrete labors into the mass of its products materializes at the same time the general social relation it carries in itself.

Since the general social relation itself, that is, the social regulation of production, is realized through the process of material production, a specific determination to this relation arises. Nothing prevents the labor-power with which society opens the circuit of its metabolism process, from being realized under some concrete forms whose products are unfitted to close that circuit. Therefore, the products of social labor are materializations of total society's labor-power in act, and materializations of socially useful labor (that is, of labor that is necessary for the realization of the social metabolism process), only as a possibility. Still, this possibility has reached by now a concrete form fitted for an immediate realization. It is realized through the exchange of the product of a concrete labor, unsuited for closing the individual metabolism process of its producer, for another one that is suited, being both equivalent as materializations of the same amount of human labor in general. As soon as the product of a private independent producer is useless to satisfy a social necessity, to close the circuit of the social metabolism process, it will show itself as incapable of attracting other use-values to be exchanged with. Despite being the materialization of a part of the total society's productive labor-power as much as any other, it ends up excluded from social labor. The human abstract labor materialized in these products - naturally inherent in all human products - thus develops the specific social determination - only inherent in the absence of a direct regulation of the social metabolism process - of being represented, insofar as it is socially necessary, as the capacity of these products for relating among themselves in exchange and, through this relation, to socially relate their producers. As it is thus represented, the socially necessary abstract labor materialized in its products becomes the value of these products. The natural forms of these products, their use-value, acquire the social form of commodities, their value form. The social metabolism process is thus autonomously regulated by determining the material production, at the same time, to become the production of the general social relation. Productive labor becomes therefore specified by this twofold determination.

The private producers lack any direct general social relationship among themselves. They must act, and consequently see themselves, as being mutually independent. They come to face their general social interdependency only through the mediation of their material products. Therefore, this relation appears to them as an attribute inherent in the material form itself of these products, as a fetishistic social relation.

When it acts as living labor, that is, as it changes its own material form as such into a newly produced use-value appropriate for the development of the social metabolism process, productive socially necessary labor creates value. Obviously, by acting, living labor transforms the use-value of the means of production it consumes into that newly produced use-value. The labor materialized in these means of production (therefore, dead labor by now) has once been confirmed as being socially necessary through the realization of their value at the time they were purchased. Still, after they are productively consumed by living labor, society has yet to confirm that it is determined to allocate the labor originally performed to produce them into the new concrete material form they have acquired. Therefore, the abstract labor originally materialized in them reappears in the value of the use-values produced by using them, as it is confirmed again as being socially necessary. In other words, living labor maintains the value of the means of production it consumes (that is, the socially necessary abstract labor materialized in them that has been represented as the capacity of these means of production for relating in exchange as commodities) as the corresponding part of the value of the new commodity it produces.

Value has no way of expressing itself directly through its substance, the socially necessary abstract labor materialized in a commodity. To do it, this labor should manifest itself as being socially necessary at the very moment the concrete labor that produces each commodity is performed. In other words, such expression presupposes that the concrete labors are performed as a directly social one, and therefore, presupposes the direct regulation of the social metabolism process. Still, if the products of labor take the social form of commodities, it is precisely because the concrete labor that produces them is the very negation of directly social labor, i.e., private labor. Only after its has been materialized, and indirectly as abstract labor, this private concrete labor can be confirmed as a part of the social labor or not. Since it is the socially necessary materialized abstract labor represented as the capacity of commodities for relating among themselves in exchange, value lacks any way for manifesting itself other than in exchange itself. Therefore, the value of a commodity necessarily expresses itself only in the use-value, in the body, of the commodity that is exchanged for the commodity in question as its equivalent. With its quantity determined by the amount of time of socially necessary abstract labor materialized in a commodity, value takes its concrete form of exchange-value; that is, of the quantity of a commodity's value that expresses itself as a certain quantity of another commodity's use-value.

Commodities are the simplest specific form of present-day general social relation. Still, until the very moment they are realized in exchange, commodities are this relation only potentially. Commodities solve this contradiction they are in themselves by determining a particular commodity as the substantive general equivalent of their community, in which all the rest of them express their value. This special commodity, money, ceases to have its exchangeability, the realization of its value, determined as a possibility; it is the direct incarnation itself of exchangeability. It thus develops a specific use-value, that of being the substantive incarnation of value, a pure materialization of the general social relation. The product of a concrete private labor becomes the direct incarnation of abstract social labor. As this materialization, money develops its functions up to reaching the ones of means of payment, hoard, and world-money. On fulfilling money these functions, the circuit of the circulation of commodities does not take the simple shape $C-M-C$ any longer, but formally ends with the step $C-M$. In the corresponding part, commodity production ceases to be a production of use-values regulated by their condition of values. It becomes specifically determined as such production, having the universal form of value itself, the general social relation in its concrete materialization, as its direct object.

The materialized general social relation that becomes the subject itself of social production and consumption: commodities as the product of social labor alienated as a capital's potency, that is, capital-commodities

Productive labor-power is not by itself a means for human life and, therefore, it is not an use-value by itself, but a moment of the human social metabolism process itself. Nevertheless, as substantive value itself becomes a direct object of social production, the power to produce value (that is, the capacity for laboring as a producer of commodities) develops the possibility of becoming an use-value. It is about the possibility of producing more value than required by its own production. Consequently, this new use-value does not concern as such the natural possessors of the labor-power at stake. It only concerns someone different from them, that gets to possess the use-value of that labor-power by purchasing it for its value as a commodity. What directly concerns those natural possessors is the fact that the separation between private labor and social labor necessary develops through a specific possibility: insofar as individuals are private independent possessors of their own productive labor-power, they may become separated from the material conditions needed to put this power into action. Once the private independent producers are separated from the means to produce their lives, the realization of their own productive labor-power faces them as a condition that is externally determined with respect to that process. Thus, this power appears to them as a non-use-value for themselves, that they posses. At this stage, they are left with no general social relation to produce their lives other than the possibility to sell this power as a commodity itself.

Since labor-power thus becomes a commodity, money negates itself as a specific direct object of social production to affirm itself as the subject that opens each circuit of social production to close it once it has valorized itself, $M-C-M'$. The general social relation takes its concrete shape as money that engenders money, substantive value that valorizes itself. Money thus transcends itself into capital. From the specific viewpoint of commodity production, it did not suffice to transform nature into a means for human life for a labor to be a part of society's productive labor. To be such, a labor needed to produce value. Now, this production does not suffice either. In capitalist production, productive labor is only that which produces surplus-value. Only when capital has realized itself as such, the human labor from which its valorization nurtures itself has produced the general social relation and, therefore, unfolded the potencies inherent in this historical form the social metabolism process takes. Capitalist production is not a production of use-values regulated by the condition of these as values. It is not even a production of use-values which is only a means for the production of substantive value. It is a production of value in itself that yields as its result the production of use-values and, hence, of human beings; it produces human beings specifically determined as capitalists and proletarians. Capital, materialized labor and, as such, a means of human social metabolism process, has taken possession of the generic potentialities of this process. Capital thus presents itself as the alienated incarnation of the generic human being. The product of social labor, a material product that is at the same time the materialized form of the general social relation, has transformed itself into the concrete social subject. From being a formally fetishistic material form, this product thus faces its own producers as the one which produces them, as a real fetish, so to speak.

The laborers realize the use-value of the means of subsistence that they indirectly get in exchange for their labor-power, through individual consumption. In part, this consumption is mediated by another material production process. The purchased means of subsistence are individually consumed by other members of the households of the wage-laborers. Thus, those means of subsistence are transformed into the labor-power of these members, which goes into action and produces new means of subsistence that finally enter the individual consumption of the wage-laborers. This production process thus involves a new allocation of social labor-power into its concrete forms. Nevertheless, considered in itself, this allocation is regulated through direct personal relations. However the use-values thus produced are materializations of socially necessary abstract labor, this labor does not need to be (and has no way of being) represented as their value-form to be determined as such social labor. The social product has apparently lost its commodity-form while it goes on flowing and being transformed inside the household. Still, this is only a specific ambit through which the general social relation realizes itself. From the point of view of the general regulation of the social metabolism process, the labor-power thus allocated, and hence, the labor-power that has provided the means of subsistence that made this production possible, follow the fate of the marketable labor-power in which they become materialized.

If this were just a production of commodities, individual consumption would bring to a complete end the general social relationship materialized in those means of subsistence. But now social production has transcended into a production of more value by means of value, and human life itself has negated itself as immediately such to affirm itself as a mere moment in the life of capital. The process of individual consumption by those who sell their labor-power is, in itself, the process in which they produce the use-value in which their general social relation is materialized and, therefore, the process in which they produce their general social relation itself. Then their general social relation is not exhausted with their individual consumption, but it reappears as the value of their labor-power. Only if this labor-power finds a buyer, the socially necessary abstract labor previously materialized in the means of subsistence needed to produce it, will be reconfirmed as such under this new material form it has taken. From capitalist society's specific point of view, the final consumption will only occur when this labor-power becomes productively consumed, which here means, consumed to produce surplus-value. In that moment, the value materialized in the labor-power will actually disappear, and the new value created by the performed living labor will be materialized in its product. If the labor-power does not find a buyer, the socially necessary abstract labor materialized in the means of subsistence will show not to be such any longer under the new material form in which it has been allocated. Therefore, it will show it has been spent under a socially useless concrete form, and consequently, an useless form for its own producers, who thus become deprived from their general social relation and, finally, from their own natural lives.

As the personifications of capital they are, the capitalists appropriate the surplus-value (that is, the surplus of socially necessary abstract labor that exceeds that of the labor-power consumed in the production process - surplus-labor - materialized in the corresponding surplus-product that represents itself as the capacity of this product for relating in exchange with other commodities) for free. Nevertheless, this appropriation is based upon the exchange of all commodities for their value. That is, the exchange of all commodities as equivalents of a common immediate social substance, the socially necessary abstract labor materialized in them. The exploitation of the direct laborers by the capitalists thus takes concrete form through the apparent equality of these two social classes as commodity producers.

The very existence of any exchange presupposes the existence of an immediate common substance materialized in its objects that makes them commensurable. However, commodities are no longer the simple product of labor. They are now the product of labor insofar as this is alienated as a potency of capital. Therefore, they are no longer simple materializations of socially necessary abstract labor that represents itself as the capacity of commodities for exchange, but this materialization only under its concrete form of materializations of valorized value, of capital. In brief, they are not simple commodities but the product of capital, capital-commodities. And they relate as such in exchange. Can socially necessary abstract labor still be the immediate common substance that enables capital-commodities to be compared as equivalents in exchange?

Since money is empty of other use-value than being substantive value, the production of money by money itself cannot embody any qualitative general determination other than the realization of a difference that is a purely quantitative one in itself. The social metabolism process has now as its general regulation the production of this quantitative difference. *The immediate common social substance of capital-commodities, that enables them to relate as equivalents in exchange, is consequently determined by the equalization of the capacity of the capitals materialized in them for realizing that quantitative difference.* The *products of labor* now have their value form determined under the concrete form of *materializations of socially necessary abstract labor that is represented as the capacity of these products for relating among themselves in exchange insofar as materializations of equally valorized values*. As soon as the process of capital's self-valorization is reproduced (obviously, regardless if in a simple or an expanded scale), this value is determined as *an equally valorized value itself that is equally valorized*.

Under its simplest form - the materialization of value that valorizes itself by metamorphosing itself into labor-power and realizing this one's specific use-value - capital is a purely variable magnitude. The production of a given quality and quantity of labor-power requires, in the average of the individual workers, the same amount of social labor. That given quality and quantity of labor-power tends to be realized with the same intensity during the same period of time, also as an average. Therefore, all its units are able to produce the same amount of value. Since all labor is reduced to simple-labor in the production of value, all capitals tend to emerge from each of their metamorphosis circuits valorized in an equal proportion. That is, the rate of surplus-value, s/v, tends to be a general one. Therefore, the equivalence of capital-commodities as equally valorized values immediately expresses itself in their simple equivalence as values. Thus far, the value embodied in each commodity reappears as being quantitatively identical to itself in the concrete form it takes as the value of capital-commodities.

Nevertheless, it does not suffice with buying labor-power to put it into action. It must be supplied with the means - instruments and objects - of production upon which it can unfold itself. The disbursement of money to buy these means of production has no immediate necessity other than the valorization of that money itself . Therefore, due to its form, this is a disbursement of capital as much as any other. Still, the use-values in which it is materialized lack any capacity for producing value by themselves. All its value could do is to reappear in the value of the commodities produced by the living labor that uses them. Since it essentially is a variable magnitude of money, capital thus negates itself as simply such to affirm itself as constant capital. But, in turn, constant capital negates itself as the abstract negation of the power to valorize itself, by imposing itself as a condition for the valorization of variable capital. Capital thus determines itself as the producer of surplus-value in its organic unity of labor-power and means of production in which variable and constant capital are respectively materialized, productive capital. In general, to a greater amount of constant capital materialized in the instruments of production, a greater productive power of the labor that productively consumes them corresponds; in turn, this greater productive power results in the productive consumption of a greater mass of constant capital materialized in the objects of production. In general again, to a greater productive power of labor, a greater power of capital to valorize itself corresponds. Hence, insofar as it is determined by the technical composition of capital, the relation between constant capital and variable capital properly shows the composition of capital as the organ that produces surplus-value, the organic composition of productive capital: c / v. Abstractly considered in its simplest determination, to a higher organic composition of capital a higher rate of surplus-value corresponds. Nevertheless, given the general conditions of valorization that correspond to a certain stage in the development of capitalism and, therefore, once determined the corresponding general rate of surplus-value, the organic composition of capital differs from one special sphere of social production to the next according to the specific material conditions that prevail in each of them. Thus concretely determined, a higher organic composition results in a lower power to valorize itself of the total productive capital placed into action.

Capitals that are identically determined as pure self-valorizing value come to differ from each other due to the specific material conditions under which each of them exercises its capacity for valorizing itself insofar as a capital disbursed in labor-power and means of production. These material conditions, that are nothing but the concrete forms through which capital realizes its qualitative determination as the production of a purely quantitative difference, thus stand up as the negation of this very realization. Since all qualitative determinations are reduced to the realization of a purely quantitative difference in capital's turnover circuit as a process of self-valorization, an equally purely quantitative base necessary imposes itself to homogenize this differentiation. Time becomes this purely quantitative necessary base, with the year as its (initially natural and thereafter historical) concrete unit.

Now then, the annual base itself embodies a further determination to the capacity for valorizing themselves of specific industrial capitals. Each portion of variable capital needs a different period of time to complete its turnover, according to the material conditions it must face in its specific sphere. These material conditions determine the length of the working-time, but also push production-time beyond working-time and determine the length of, in the strict sense, circulation-time. Therefore, a given amount of variable capital can complete a greater or lesser quantity of turnovers in a given time, depending on the special sphere this disbursement takes place. Since it emerges from each of these turnovers valorized at the general rate of surplus-value, a given amount of money advanced as variable capital renders a greater or lesser amount of surplus-value in a given period of time. And this difference in the valorization capacity of an advanced variable capital formally extends itself to the constant capital that must be advanced to put labor-power in action. Therefore, from here on we will indicate this determination directly by its concrete form, i.e. the different turnover rates of capitals. Only those capitals with a unitary annual turnover rate have the same capacity for valorizing themselves whether this capacity is considered on the basis of each turnover or the year.

This double self-negation of capital as a value that valorizes itself proportionally to its own magnitude takes shape in the value of the capital-commodities insofar as this value is determined by the organic unity of each individual productive capital in each of its turnovers. However much these commodities may be mutually equivalent as the simple products of labor, or better stated, because they are such, they are not yet determined to be equivalents as the products of capital. The equalization of the rate of surplus-value in each circuit of variable capital is thus unfitted to express the equivalence between capitals as simple values that valorize themselves. Capital can no longer express its capacity for self-valorizing in the organicity of that rate. The expression of this capacity develops its first concrete form as the formal (therefore, external) relation between the surplus-value produced in each turnover circuit and the total capital advanced to achieve this production. Capital thus determines its profit rate inside each of its turnover circuits: $s/(c+v)$. Next, this formal expression overcomes the differences that emerge from the specific turnover rate of each variable capital. It does so by becoming determined as the relation between the total surplus-value produced on a yearly basis and the total capital advanced for this production in each special sphere. The capacity of productive capital for valorizing itself thus takes its concrete form as the annual rate of profit of each individual capital.

Insofar as the annual rate of profit is immediately determined by the individual valorization of each capital, it cannot go beyond being the crystallized expression of the general nonequivalence of commodities that embody the same amount of abstract labor, as the products of capital. Since capital is the concrete form of the general social relation among the independent private producers, it lacks any unity as society's total capital other than being the collection of all individual capitals. Nevertheless, it is in this external unity that the fracture of capital-commodities as the materialization of socially necessary abstract labor and of equally valorized value becomes canceled. Under its concrete form of society's total capital, capital reestablishes the unity between its organic and its formal power to valorize itself. It is now this unity that realizes its necessity by determining the individual capitals as the concrete forms of the total social capital. Productive capital has to reach its complete externality to be determined as total social capital. Consequently, individual capitals are determined as social capital's concrete forms without involving any determination other than the purely quantitative one of being, each of the former, an aliquot part of the latter. That is, individual capitals become the concrete forms of total social capital without keeping any specific difference among themselves other than their relative amount during a given time. Each individual capital realizes its necessity as a concrete form of total social capital by contributing to total surplus-value in accordance with its specific conditions of valorization and taking from this total surplus-value the pro rata part that corresponds to it. The formal power to valorize themselves of the individual capitals is thus determined as the general annual rate of profit. Given the form itself it is determined, this general rate realizes itself as such by taking the concrete form of an average, namely, the average annual rate of profit.

Once it is determined as materialized socially necessary abstract labor that represents itself as the capacity of commodities for relating among themselves in exchange - and thus to socially relate their producers - in their concrete equivalence as materializations of that same labor proportionally multiplied as such, the value of commodities takes its concrete form of price of production. The development of commodities into capital-commodities is in itself the transformation of surplus-value into average profit and, therefore, the transformation of values into prices of production. The realization of the general rate of profit is the concrete form through which the total productive labor-power of society is allocated under its concrete forms in capitalist society.

At this stage, the means of subsistence consumed by the productive-laborers to produce their labor-power with the concrete attributes that correspond to the prevailing productivity and intensity of labor and the length of the working day, circulate at their prices of production. These prices are now the concrete form of value that reappears as the value of labor-power. The value of labor-power itself thus develops its concrete form of price of production. Now, even in circulation, the natural possessors of labor-power show they have became the incarnation of valorized value, the alienated product of the fetishistic general social relation that autonomously regulates human life, of capital. And they show, even in circulation, that they are such product as the product of total social capital, therefore, not individually but, as *a* *class*, as *the proletariat*. Nevertheless, from the inverted point of view of capital's apologists, the exchange of equivalent capital-commodities in circulation, that is in itself the appropriation of the surplus-product of the wage-laborers by the capitalists beyond any equivalence, has reached the perfect ideological form: it is about everybody seeking the valorization of their capital, most of them their "human capital," the absolute minority, their "material capital," for the harmonious equilibrium of social life to be achieved.

Capital-commodities as equally valorized values

With the development of surplus-value into average profit, society's total capital shows to be the alienated concrete subject of the social metabolism process in capitalist society. The annual circuit of this capital gives its unity to the development of exchange-value into prices of production. The annual circuit in question manifests itself as that of commodity-capital; $C' \ldots C'$, in its simplest form. Since this development involves the production of surplus-value itself, we need to reflect in the circuit of commodity-capital the movement of productive capital inside each special sphere of production. The circuit of social capital thus appears as the aggregate of the circuits of valorization developed during the year, $c + v + s = C'$, in each sphere. Let us consider that this circuit is fragmented in *n* special spheres as we represent the determinations at stake in general, and in five spheres, when we consider their concrete quantum. In the latter case, we will isolate each of the basic determinations by producing two separated representations. The general case and the first concrete one, correspond to all portions of social capital having a unitary annual turnover rate, $(v+c)/C$, with their specificity reduced to their different organic compositions. In the second concrete case, all capitals have the same organic composition but differ in their turnover rates. Let us also consider that there is only circulating capital, with a single turnover rate both for its variable and constant parts inside each sphere. Let us finally assume that the value of all commodities is indistinctly expressed in ('... of) units of the money-commodity (ounces of gold) or in ('... of) units of any of the signs that take the place of this commodity in circulation ($, £, etc.).

As long as each individual capital valorizes itself in immediate accordance with the specific material conditions prevailing in its sphere, so the value of capital-commodities immediately appears under its simplest form in circulation, the annual circuit of social capital results:

$$c_1 + v_1 + s_1 = C'_1$$

...

$$c_n + v_n + s_n = C'_n$$

where

$$\frac{s_1}{v_1} = \ldots = \frac{s_n}{v_n}$$

but

$$\frac{c_1}{v_1} \neq \ldots \neq \frac{c_n}{v_n} \qquad \text{or (only to indicate the possibility)} \quad \frac{v_1 + c_1}{C_1} \neq \ldots \neq \frac{v_n + c_n}{C_n}$$

so

$$\frac{s_1}{c_1 + v_1} \neq \ldots \neq \frac{s_n}{c_n + v_n}$$

In the concrete cases,

Under its simplest form, the transformation of surplus-value into average profit takes shape in the transformation of values into prices of production as a result of the annual process of capital valorization. That is, it takes shape in the transformation of commodities, from being the simple product of labor, into their concrete form of the products of capital as materializations of equally valorized values. Taken in itself as it is directly determined by the formation of the general rate of profit (*p*), we represent this transformation as the development of the value of the product of each sphere (C'_i), into its concrete form of price of production ($C'_i t_i$), by representing the external unity of total capital as the necessity inherent in a system of simultaneous equations. That is:

$$(c_1 + v_1)(1 + p) = C'_1 t_1$$

$$\dots$$

$$(c_n + v_n)(1 + p) = C'_n t_n$$

$$\frac{\sum_{i=1}^{n} s_i}{\sum_{i=1}^{n} c_i + \sum_{i=1}^{n} v_i} = p$$

In the concrete cases,

Since we are now representing the quantitative concrete forms taken by the transformation, all the determinations involved (that is, the affirming of value by means of its own negation as the general social relation in present-day society) appear here as being developed through a set of external relations - rupture and unity - between the magnitude of these determination's concrete forms. In the simplest form we are considering, the development of surplus-value into average profit is immediately reflected by the quantitative relations that correspond to the transit from the organic determinations of capital's valorization to the formal relations in which this valorization takes concrete form. Thus, the general negation of materialized socially necessary abstract labor by its own expression as the concrete equivalence in exchange of capital-commodities, immediately manifests itself: individual prices of production differ from their simplest determination as values. Nevertheless, at the same time, value shows it is affirming itself through this self-negation by appearing quantitatively unchanged in its concrete form of price of production in what concerns the product of total social capital. And it does the same, concerning the specific capital that formally expresses by itself the determination of individual capitals as aliquot parts of total capital, namely, the specific capital whose organic composition and turnover rate correspond to the social average.

In this simple transformation of surplus-value into average profit, surplus-value's content of materialized surplus-labor manifests itself in a similar way. For individual capitals in general, self-valorization appears as a matter of mere proportionality. Nevertheless, the surplus-value and the ratios that correspond to the organic and formal relations of valorization of total social capital (directly as such or as it is represented by the specific average capital) immediately show the essence of the determination at stake. They thus show that it is about the share in the total surplus-value, extracted from the labor-power by each specific capital in accordance with the conditions prevailing in its sphere of production, among these capitals as aliquot parts of the total social capital. Therefore, the exploitation of wage-labor by capital as a necessarily collective process is immediately shown, even as a purely quantitative relation. And the same happens with the fact that this transformation itself leaves the capacity of the total social capital for valorizing itself untouched.

Any change in the conditions that directly or indirectly affect a specific valorization process develops, above all, into a change in the price of production of the corresponding commodity. Nevertheless, certain changes in the circuit of productive capital do not affect the value of commodities and, consequently, neither the valorization process nor its expression in the rate of surplus-value. This happens when the change takes place in the length of the production process beyond the labor process or directly in the length of the, in the strict sense, circulating process. In these cases, the value of the respective commodity remains unchanged, but its concrete form of price of production develops a determination of its own that makes it change. Furthermore, whichever the special sphere where it happens, any change in the circuit of a productive capital necessarily affects the determination of prices of production beyond that specific sphere. It necessarily comes into the determination of the average rate of profit and, consequently, of the prices of production in general, in three ways. In the first place, it changes the amount of society's total advanced capital keeping the total amount of surplus value unchanged, it changes the latter keeping the former unchanged, or it results in a combination of both effects. In the second place, if the amount of the capital advanced in the specific sphere changes, its proportion as an aliquot part of total capital does the same. In the third place, if the capital released (tied-up) in the directly affected sphere of production does not proportionally come from (go to) all of the spheres, a second change in the general distribution of total capital among the different spheres takes place. From all this, a change in the average organic composition of capital takes place. And this change, that is completely alien to what happens with the productivity of labor, changes in turn the amount of surplus-value that total social capital renders in a year, even though its own amount remains unchanged. Let us assume in our example that the time of circulation of capital *V* changes, doubling its turnover rate, and that the corresponding released capital becomes again tied-up to this sphere, making its production to double. We thus have:

- change in values

The general rate of surplus-value can only change if the length of the working-day (and therefore, the absolute surplus-value) changes, or if the value of labor-power (and therefore, the relative surplus-value) changes. A change in absolute surplus-value directly concerns social capital as such, with the capitals of each sphere acting as the mere specific vehicle of the generic necessity. On the contrary, a change in relative surplus-value emerges from the change of the productive power of labor in each specific sphere. But it emerges only from such change in the spheres that, directly or indirectly, produce the means of subsistence for the productive wage-laborers. The corresponding change in the spheres that directly or indirectly provide for the individual consumption of the capitalists lacks any power to change the general rate of surplus-value. Nevertheless, as soon as a change in the productivity of labor affects the allocation of the advanced capital between the different special spheres in a non-proportional way, it affects all the prices of production, whichever the sphere the change takes place. Moreover, the transformation of values into prices of production comes into the determination of the general rate of surplus-value itself, as it determines the magnitude of each social necessity and, therefore, the proportion of total capital advanced in each special sphere (nevertheless, we are going to focus on this determination later).

Abstractly considered in itself, a change in the value of labor-power (remaining the rest of its determinations untouched) does not affect the labor-time needed to produce the commodities in general, and therefore, their values. It only implies an increase or decrease in the productivity of labor and, therefore, in the organic composition of capital, in some of the specific spheres that produce the labor-power. Since this change affects the general rate of surplus-value and, consequently, the average rate of profit, it affects the price of production of all commodities. Still, at the same time, it manifests itself as a change in the value composition of the capitals of all spheres. This latter change does not arise from a change in the technical composition of the capitals where it takes place and, therefore, it is not a change in the organic composition of these capitals. Nevertheless, with the mediation of the difference in the organic composition of the individual capitals, this change in their value composition changes the proportion that each of them represents as an aliquot part of the total social capital in a specific way. Those with an organic composition beneath the average get their share changed in a direct relation with the change in the value of labor-power; those with an organic composition above the average, get their share changed in an inverse relation. Only those with the average organic composition keep their share unchanged. Thus, the prices of production of those commodities produced by capitals with an organic composition beneath the average will rise (fall) as a rise (fall) in wages relatively rises (lowers) the value of these capitals. Conversely, the prices of production of those commodities produced by capitals with an organic composition above the average will fall (rise) as a rise (fall) in wages relatively lowers (rises) the value of these capitals. And the prices of production of those commodities produced by capitals with the average organic composition will remain unchanged in either case. A 50% rise in wages in our example will result in:

- change in values

Thus far, we have followed the process in which surplus-value negates itself as simply such to affirm itself under its concrete form of average profit - and, therefore, the process in which the value of commodities develops its corresponding metamorphosis into price of production - as capital determines itself as an amount of value that proportionally valorizes itself on an annual basis. This is only just the first step in the transformation of commodities from being the immediate product of labor, to become the specific product of capital. Nevertheless, it suffices to make the concrete forms that value and surplus-value take for each specific capital appear as their absolute and, therefore, abstract negations, as soon as these concrete forms are immediately - therefore, externally - faced through their relations of measure. Even so, at this stage, profit and prices of production immediately show they are the concrete forms of surplus-value and value as they appear in the relations of measure that concern total social capital as such, or as this capital is represented by average specific capital.

Capital-commodities as equally valorized values that equally valorize themselves

With the reproduction of the circuit of capital valorization, capital transcends its determination as an amount of value that proportionally valorizes itself to become proportionally valorized value that proportionally valorizes itself. It is no longer just about unfolding the concrete forms that the transformation of values into prices of production takes as capital emerges from its circuit of valorization at them. It is about this unfolding when the value of capital has already undergone such transformation as a premise of its circuit of valorization.

In the first place, we must face the specific determinations of prices of production that emerge from the reappearance, in these prices, of the price of production of the constant capital productively consumed. The transformation of the value of the means of production into their price of production does not add to this reappearance any specificity other than the quantitative difference between those values and prices itself. At the same time, the difference between the value and the price of production of constant capital affects the amount of capital that must be advanced to perform the annual process of valorization. Therefore, it affects the proportion that the capital advanced in each specific sphere represents as an aliquot part of the total social capital.

At first sight it could appear that a certain net difference in the price of production of the means of production should result in differences in the cost price of production and in the advanced capital - and consequently in the price of production - of the commodities produced, having the same sign. Nevertheless, the general relation between the capital annually consumed and the capital advanced for this consumption - that is, the turnover rate of the former - mediates here. Only when the advanced capital completes a single turnover circuit during the year (and, therefore, has an unitary turnover rate) the difference between its value and its price of production appears identical to itself in the cost price of production. A turnover rate above the unit implies that the divergence in the advanced capital will appear multiplied in the cost price of production; thus, until a vanishing divergence in the former becomes infinitely multiplied in the latter, when capital instantaneously completes its circuit. Conversely, a turnover rate beneath the unit makes the divergence in the advanced capital appear as a diminished one in the cost price of production; thus, until the latter divergence vanishes away as the turnover rate approximates zero. The net differences in the advanced capital and in the cost price of production result from the algebraic summing up of the differences produced by each portion of constant capital. From which, net differences in the same direction but of divergent magnitude, or diverging both in direction and magnitude, between the value and the price of production of the advanced and consumed capital may result. Let us assume the following constant capital:

	advanced capital		turnover rate	consumed capital	
means of production	value	price of production		value	price of production
a	100	140	0.1	10	14
b	100	85	1.0	100	85
total	200	225		110	99

While the price of production of the advanced capital increases a 12.5% above its value, the cost price of production of the commodity produced by consuming it falls a 10% beneath its cost value.

As far as variable capital is concerned, the difference between the value and the price of production of the means of subsistence for the productive wage-laborers affects the amount of capital that must be advanced in wages to perform the annual process of valorization. Consequently, this difference affects the proportion that the capital advanced in each specific sphere represents as an aliquot part of the total social capital. Whether advanced capital indirectly takes the material form of those means of subsistence or directly the material form of means of production, it behaves exactly in the same way concerning the share of each specific capital in total capital. Therefore, we will consider it in this unity to develop the concrete forms that this determination takes.

If in a specific sphere the price of production of the advanced capital is higher (lower) than its value, this capital increases (diminishes) its share as an aliquot part of social capital. Still, this simple determination undergoes a specific mediation. Those positive or negative differences are proportional to the relation between the organic composition of each capital that has produced the commodities that are going to come into action now as means of production, and the average organic composition in the circuit these commodities were produced. The proportionality in question only applies with respect to the total product of that circuit. Therefore, the proportion in which the price of production of a commodity differs from its value will immediately reappear as the proportion in which the new capital materialized in it sees its own share as an aliquot part of the total capital increased or decreased, only if the total product of the previous circuit becomes capital in the new one. Given the consumption of the capitalists, this is not the case. The proportion in which a price of production represents a higher (lower) part of the total valorized value normally differs from the proportion in which this same price represents a higher (lower) part of the value of the total capital that opens the following circuit. The latter proportion is mediated by the relation between the organic composition of the specific capital that has produced each commodity that is going to become new productive capital and the average organic composition of the capitals that have produced the rest of the commodities that are to follow this same course. Thus, a price of production above (bellow) the respective value, as it results from a capital with a higher (lower) organic composition than the corresponding social average, can finally result in a reduced (increased) share in the total social capital for the next circuit. An average organic composition of the capitals that produced this new total capital high (low) enough with respect to the organic composition of the specific capital in question so as to overcome the original divergence, is all this inversion requires. For instance, let us assume a capital that, according to its value, represents the 10% of the total capital, and whose price of production is 5% higher than its value. Let us also assume that the price of production of this total capital is 20% higher than its value and that this value has represented the 60% of the total product in the circuit it was produced. Let us finally assume that the remaining 40% of that total product corresponds to the surplus-value individually consumed by the capitalists, whose price of production is 30% lower than its value. Under these conditions, the specific capital in question will not have a 10% increased share in total capital, but a 12.5% diminished one.

At first, prices of production simply diverge from values because the organic composition of the capital in each special sphere diverges from the social average. Now, this original divergence may result increased, diminished or even inverted in its direction, as soon as the same determination projects itself from one turnover of capital to the next. For instance, a *ceteris paribus* rise (fall) in wages may end up manifesting itself as a fall (rise) in the price of production of a commodity produced by a capital with an organic composition beneath (above) the average, as the direct effect can be indirectly counteracted. It does not suffice any longer with an organic composition equal to the average for a special capital to produce a commodity whose value appears as a magnitude identical to itself under its concrete form of price of production. This primary condition extends to the whole of the capitals that indirectly (that is, by producing in previous circuits the material elements that now act as capital, and so on backwards) participate in the production of the commodity in question. Yet, this condition thus not suffice by itself to keep a value unchanged through its transformation. The capitals that produce the material forms that are going to act as capital in the next circuit must have, as an average, the average organic composition. The necessary simultaneous fulfilling all these conditions, means the practical impossibility - excluding an accidental compensation - of a commodity whose value would appear as an untouched magnitude when transformed into a price of production, as soon as capital opens its circuit already as valorized value.

We have thus followed the determinations of the prices of production that emerge from the circulation of capital-commodities at these prices as a premise for the circuit of capital's valorization. Let us focus now on the new value created in this circuit. The first part of this value corresponds to the labor needed by the productive-laborers to reproduce their labor-power, so as to make it available for the next circuit. Let us abstract here from any change in the magnitude of each social necessity due to the change in prices itself, that will come in only when we face the concrete form that the transformation takes through competition. Under this condition, the productivity and intensity of labor and the length of the working day are, in themselves, alien to the circulation of commodities directly at their value or at the concrete form this value takes as price of production. Therefore, from a purely material point of view, the amount of labor needed to reproduce each unit and the social totality of labor-power remains intact. The same happens with the specific social form this labor takes in commodity production, as the socially necessary abstract labor materialized in its product that is represented as the capacity of this product for relating with the rest of the commodities as equivalents in exchange. Still, it happens now that this product has its concrete social equivalence determined as the product of an equally valorized value. The price of production of the means of subsistence needed to reproduce the labor-power consumed in each special sphere determines the concrete form that the corresponding part of the value of the commodities produced in that sphere takes as their price of production. When, *ceteris paribus*, the productivity of the labor that directly or indirectly produces the means of subsistence for the labor-power rises (falls), the value of these means falls (rises), with its corresponding manifestation in their price of production. With that change in productivity, a smaller (bigger) portion of the living labor performed in each sphere is needed to reproduce the labor-power consumed in it. The remaining (additional) part of the value created by this labor will change the form in which it is transformed into a price of production, as it ceases to be (becomes) a materialization of necessary-labor to become (cease to be) a materialization of surplus-labor.

The second part of the new value created in each circuit corresponds to the product of the surplus-labor rendered by the productive-laborers, that the capitalists appropriate for free as surplus-value. We have already seen how the surplus-value materialized in capital-commodities develops its concrete form of average profit when these commodities are determined as equivalent materializations of proportionally valorized values. At that stage of its development, the average profit materialized in the product of each specific capital was determined as this capital's share in the mass of the social total surplus-value - to which it contributes according to its organic composition and turnover rate of its variable part - as corresponds to it as an aliquot part of total capital. Therefore, the average profit was determined as an immediate mass of value itself. Nevertheless, as soon as we have advanced into capital's concrete form of equally valorized value that equally valorizes itself, not a single portion of value can immediately appear as such, but under its concrete form of price of production. Not even the organic composition of capital, or its turnover rate, go on directly appearing here as the immediate determinants that make capitals differ in their capacity for valorizing themselves. Therefore, this average profit must reach its concrete form now through prices of production themselves. Nevertheless (as what directly happens with the values of simple commodities) these prices of production and, thus, their part determined as average profit, have already reached their complete determination for the individual capital-commodities when these commodities come into circulation. Externally seen, as they are the representations of the common social substance that actually enables capital-commodities to relate as equivalents in exchange, their full determination precedes exchange itself, thus being a condition for circulation and never its result. Circulation only turns this determination socially visible.

Individual capitals lack the capacity for directly determining themselves by themselves as concrete forms of social capital. They cannot realize the general rate of profit, that is their true determinant as aliquot parts of total capital, directly as such. On the contrary, this rate can only manifest itself once it has been realized through the prices of production it determines. It thus necessarily appears inverted as a purely formal relation between the average profit appropriated by each capital and this one's advanced amount. Individual capitals can only realize their determination as concrete forms of social capital when they relate with each other - and therefore, socially relate the capitalists that personify them as the holders of the proportional part of the social product in which the surplus-labor has been materialized - by exchanging their products, that is, through competition. And only in this way they can realize total social capital's necessity as the concrete subject of the social metabolism process; that is, its necessity to reproduce itself, to reproduce its circuit of valorization.

When all individual capitals get together in competition, surplus-labor presents itself in a twofold materialization, from total social capital's point of view. It is materialized in the corresponding part of the commodities produced by each individual capital. But, at the same time, it is materialized in the whole product of the capitals that produce the commodities for the individual consumption of the capitalists and their cohort of parasites, plus the whole product of the capitals that produce the material forms that will enter the next circuit as additional capital. Always from total capital's point of view, surplus-value completes its realization starting from the former materialization, $C' < \begin{matrix} M \\ m \end{matrix}$, in the same act that it does so starting from the latter one, $m - C_{(m)}$. Only when all the capital-commodities that attempt to come into circulation are exchanged there at their prices of production as equivalent materializations of equally valorized value that has been equally valorized, these two portions of total social product can come together with their social form determined as average profit. As long as this does not happen, the part of the total social labor whose product is sold under its price of production, or that cannot be sold at all, will show it has been allocated into its concrete forms in a socially useless way. On the contrary, those capital-commodities sold at market-prices above their prices of production will make evident that society needs to allocate a higher part of its total labor-power into the respective concrete forms. Therefore (and as it is proper of any concrete form of the autonomous system through which the social metabolism process regulates itself), average profit necessarily appears in its realization as a process of equilibrium that has the perpetual lack of equilibrium as its necessary concrete form. From a purely formal point of view, surplus-value will appear under its fully developed concrete form of average profit, as the sum of the prices of production of the commodities produced by the specific capitals that close their circuits through $m - C_{(m)}$.

We have reached again the price of production of capital as a result of its process of self-valorization. A certain social capital - which is itself the materialization of the social labor consumed to produce it - is able to place into action in a year a certain amount of labor-power able to work with a certain productivity and intensity over a working day of a certain length. The living labor thus performed renders a certain value product, while it preserves the value of the means of production it consumes in the working process. The total value of the product that comes into circulation becomes thus determined. Neither more nor less social labor can fit in exchange than the materialized in the commodities that are thrown into circulation together. Therefore, when a commodity is exchanged at its price of production as the concrete equivalent of other that embodies more social labor than it does, the latter is exchanged as the concrete equivalent of less materialized social labor in the same proportion. The quantitative differences between the values and the prices of production tend to mutually eliminate themselves inside the total social capital that emerges from the annual process of valorization. This simple quantitative determination immediately shows as such when capital-commodities are determined as equally valorized values. Nevertheless, by now, it has gone through the development of capital-commodities into their concrete from of equally valorized values that have been equally valorized. The simple determination remains immediately effective as far as the new value created itself is concerned. In turn, the differences that emerge from the proportion that each specific capital represents with respect to the total social capital advanced for the annual production necessarily balance one another, given their own relative nature. This is not the case with the projection of the divergence between the value and its concrete form of price of production for the capital materialized in the means of production that turnovers as fixed capital. The immediate counterpart of this divergence concerns the complete amount of a fixed capital, that is, its amount as advanced capital, but not the partial reappearance of this capital in the value of its product, as it is gradually consumed each year. Nevertheless, the magnitude and the direction the differences in question may present keep no specific relationship whatsoever with the turnover rate of fixed capital in each sphere. Consequently, these differences tend to balance each other inside society's total fixed capital. Circulating constant capital has no role to play here, as the value of its elements completely reappears in each of its turnover circuits, thus entering the general compensation in an immediate way. In brief, the value of the total social product goes on appearing as an unchanged magnitude under its developed concrete form of the price of production of the social capital that annually emerges from its process of valorization.

None of the necessary compensations in question inheres in the specific portions of total social capital determined as constant capital, variable capital and average profit. Therefore, their prices of production appear as magnitudes that differ from their value content. Each of these specific parts will have its magnitude relatively changed according to the respective organic composition and turnover rate of the capitals that directly and indirectly produce it, as these determinants impose themselves through the more developed mediations we have already seen. Of course, these organic compositions and turnover rates differ in their relative magnitudes for every time and place according to the prevailing concrete material conditions of production and circulation. Still, a general relation makes its way through these circumstantial conditions. Let us briefly face it here.

However inverted as an alienated potency, capitalist production is a historically determined specific social form through which humanity produces its life. And human life is a social process that has no concrete form of realizing its necessity other than individual life. By following a more or less convoluted path where their material forms suffer successive changes, all capitals reach individual consumption. In other words, all the capitals that produce means of production indirectly take part in the production of the means of subsistence for the wage-laborers or of the commodities that the capitalists individually consume. In fact, the social division of labor acquires its capitalist specificity as the chains of successive material production processes are cut off by the circuits of different individual capitals. What basically matters here, is the relative course followed by the organic composition and turnover rate of capital when the production processes in general enter what the fragmentation of individual capitals determines as their last step (that is, when the commodity produced ceases to be a means for a subsequent material production to become a means for individual consumption). Do they develop any necessary specificity with respect to their magnitudes in the average of the capitals that have preceded this step?

The capitals that directly produce the means of subsistence for the wage-laborers include both extremes in the scale of the organic composition. It includes automated productions in the greatest massive scale, but also productions that can only be performed in the very moment and place where individual consumption occurs. Depending on the degree of capital's fragmentation and of the material complexity required to transform the same means of production into a means of individual consumption, the capitals that produce the latter can include or exclude some with a specifically low turnover rate. This typically concerns agricultural production, where production-time extends far beyond working-time, due to the submission of productivity to natural conditions beyond the control of normal capitals. All in all, there is no determination that forces a specific bias into the price of production of variable capital with respect to its simple determination as value, vis-à-vis what happens concerning the constant capital that directly or indirectly takes part in the production of the labor-power.

Let us consider now the capitals that directly and indirectly produce the means for the individual consumption of the capitalists. In general, as this production advances through its successive steps, its material form tends to become increasingly differentiated from that which corresponds to the production of the means of subsistence for the wage-laborers. The scale in which those steps are performed experiments a progressive fall compared with the scale that the former production takes. At the same time, the social nature itself of the necessities these use-values satisfy determines a high relative use of living labor in their production, which also increases as the production process advances. Both determinations reach their peak in the last step of this process, which directly produces the means of individual consumption for the capitalists. And both of them result in a relatively low organic composition of the capitals involved in this production. Since some of the capitals that produce means of production are thus determined, the price of production of constant capital is affected in the corresponding proportion. Still, this relatively low organic composition only turns into a specific determination of the price of production of the specific portions of total social capital as it determines the prices of production of the articles of luxury that the capitalists individually consume. It relatively lowers the magnitude with which the surplus-value appears as average profit, and consequently pushes up the prices of production of constant and variable capital. Nevertheless, not all the surplus-value follows the ignoble destiny of becoming an article of luxury for the capitalists and their confederates to consume. Since the process of valorization only realizes its essential necessity as a process of accumulation, a part of the surplus-value has its material forms determined as the new means of production and means of subsistence needed to reproduce itself in an expanded scale. The production of these material forms does not differ in any meaningful specific way from the production of the means of production and means of subsistence for the productive-laborers already in action, in what concerns here. Therefore, the same happens with respect to the organic composition and turnover rate of the variable part of the capitals that produce them. The same general determinations mediate in the prices of production of the constant and variable capitals and in the part at stake of the surplus-value as average profit. The specific determination initially developed becomes smoothed.

As soon as the value contained in each specific part of the total social capital takes its concrete form of price of production as a different magnitude of equally valorized value that has been equally valorized, the quantitative relations among them will no longer reflect in an unequivocal way the organic determinations of capital's valorization. Moreover, although there is nothing at stake here apart from the development of these organic determinations into formal ones, the quantitative relations in question will not even reflect in an unequivocal way the simplest forms of these formal determinations. At best, the organic relation between variable capital and constant capital could be properly reflected by its average in time. But any relation that places together the simple forms of capital and surplus-value unavoidably becomes distorted when it is expressed through their concrete forms. The real power of capital to valorize itself, and therefore, the power to exploit the productive wage-laborers by making them render surplus-labor, appears underestimated. This happens with the rate of surplus-value, but also with the general rate of profit. Nevertheless, this is not just a distortion in the manifestation of the simple relation. The general rate of profit itself, (*p*), has reached here a more developed concrete form as the formal expression of capital's power to valorize itself when it opens its circuit already determined as an equally valorized value. Under this concrete form, (p^c), the general rate of profit does not appear as the determinant that rules the formal equalization of capitals any longer. It appears with this simplest determination inverted, that is, as the expression of the realized necessity of this equalization. And as such it goes on appearing as it develops its even more concrete form when the surplus-value materialized in the expenses of circulation becomes formally determined as advanced capital (but this development falls beyond the determination of the prices of production themselves). From which, the agents of capital who personify that realization see the general rate of profit as having no content other than its emergence itself.

Only if all the surplus-value produced in a turnover circuit becomes new capital in the next - which presupposes the annihilation of individual capitalists - the concrete general rate of profit can immediately tend to quantitatively coincide with its simple expression. In this case, both the price of production of the social capital and of the surplus-value are determined through the mediation of capitals with the same average organic composition and the same turnover rate. Let us consider a final relevant point concerning the distorted manifestation of the simple relations of valorization through their apparent concrete forms as relations between the completely developed prices of production. As capital accumulation develops, an increasing part of total surplus-value is transformed into new capital at the expense of the part individually consumed by the capitalists. *Ceteris paribus*, the organic composition of social capital rises. Since this rise does not proceed from an increased productivity of labor, it tends to produce a fall in the rate of surplus-value. Nevertheless, this rate could appear as following the opposite direction when it is improperly computed on the basis of the completely developed prices of production. This happens as soon as its real fall is apparently overturned by the relative increase in the price of production of average profit and the opposite movement concerning variable capital, as the organic compositions of the capitals that produce each of them tend to converge. The same inverted appearance will emerge under these circumstances respecting the general rate of profit. This is not one of those causes that genuinely counteract the tendency of the rate of profit to fall with the development of capital accumulation. It is just a purely apparent effect on the power of capital to valorize itself, as it becomes expressed in the concrete form the annual rate of profit takes.

As we have already seen, although the general rate of profit actually determines the complete development of values into prices of production through its formation, its correspondingly developed concrete form has its magnitude determined as a result emerging from that transformation itself. Therefore, it cannot be placed at this stage in the model we use to represent the quantitative determinations at stake, as the direct determinant of the external unity of total social capital. It only fits there as being itself quantitatively determined by the very realization of this unity. The external unity of total capital can only manifest itself now through the necessary quantitative identity that the value of the total annual product maintains all along its development into price of production. Besides, capital becomes now an incarnation of equal valorization not only as a result, but also as a premise of its circuits. The transformation of its value into price of production does not only take place inside each annual turnover circuit but projects itself from one circuit to the next in the reproduction of the valorization process. Therefore, we need to identify the spheres according to the type of use-value they produce. Let us consider that, in the general case, the spheres $1, ..., l$ produce means of production, the spheres $(l+1), ..., m$, means of subsistence for the productive wage-laborers and the spheres $(m+1),...,n$, commodities for the individual consumption of the capitalists.

Obviously, any change in values inside a circuit or from one circuit to the next is out of the question concerning their development itself into prices of production. Consequently, we will only indicate the circuit *k* that corresponds in each case, provided this identification is meaningful in itself. As we have already seen, prices of production are alien to the scale in which capital's reproduction takes place, provided this reproduction preserves the proportion each specific capital represents in the total. Since this simplest determination corresponds at this stage of our representation, we can either consider simple or expanded reproduction. Still, the reproduction of capital's valorization only fits into a single-year model on the basis of its simple form (as it happens whichever question related with this reproduction one faces). Under these conditions, the annual circuit of social capital as a simple process of production of value appears as:

$$c_{11} + \cdots + c_{1l} + v_{1(l+1)} + \cdots + v_{1m} + s_1 = C'_1$$

$$\ldots$$

$$c_{l1} + \cdots + c_{ll} + v_{l(l+1)} + \cdots + v_{lm} + s_l = C'_l$$

$$c_{(l+1)1} + \cdots + c_{(l+1)l} + v_{(l+1)(l+1)} + \cdots + v_{(l+1)m} + s_{(l+1)} = C'_{(l+1)}$$

$$\ldots$$

$$c_{m1} + \cdots + c_{ml} + v_{m(l+1)} + \cdots + v_{mm} + s_m = C'_m$$

$$c_{(m+1)1} + \cdots + c_{(m+1)l} + v_{(m+1)(l+1)} + \cdots + v_{(m+1)m} + s_{(m+1)} = C'_{(m+1)}$$

$$\ldots$$

$$c_{n1} + \cdots + c_{nl} + v_{n(l+1)} + \cdots + v_{nm} + s_n = C'_n$$

where,

$$\sum_{i=1}^{n} c_{ij} = C'_j \text{ for } j = 1,\ldots,l; \quad \sum_{i=1}^{n} v_{ij} = C'_j \text{ for } j = (l+1),\ldots,m; \quad \sum_{i=1}^{n} s_i = \sum_{i=(m+1)}^{n} C'_i$$

and

$$\frac{s_1}{\sum_{i=(l+1)}^{m} v_{1i}} = \ldots = \frac{s_n}{\sum_{i=(l+1)}^{m} v_{ni}}$$

but

$$\frac{\sum_{i=1}^{l} c_{1i}}{\sum_{i=(l+1)}^{m} v_{1i}} \neq \dots \neq \frac{\sum_{i=1}^{l} c_{ni}}{\sum_{i=(l+1)}^{m} v_{ni}}$$ or (only to indicate the possibility)

$$\frac{\sum_{i=1}^{l} c_{1i} + \sum_{i=(l+1)}^{m} v_{1i}}{C_1} \neq \dots \neq \frac{\sum_{i=1}^{l} c_{ni} + \sum_{i=(l+1)}^{m} v_{ni}}{C_n}$$

so

$$\frac{s_1}{\sum_{i=1}^{l} c_{1i} + \sum_{i=(l+1)}^{m} v_{1i}} \neq \dots \neq \frac{s_n}{\sum_{i=1}^{l} c_{ni} + \sum_{i=(l+1)}^{m} v_{ni}}$$

When capital realizes its necessity as equally valorized value that equally valorizes itself, these values develop their simplest concrete form of prices of production, $c_{ij}\, t_j^c, v_{ij}\, t_j^c, C'_i\, t_i^c$, as:

$$\begin{gathered}
\left(c_{11}\, t_1^c + \dots + c_{1l}\, t_l^c + v_{1(l+1)}\, t_{(l+1)}^c + \dots + v_{1m}\, t_m^c\right)\left(1 + p\right) = C'_1\, t_1^c \\
\dots \\
\left(c_{l1}\, t_1^c + \dots + c_{ll}\, t_l^c + v_{l(l+1)}\, t_{(l+1)}^c + \dots + v_{lm}\, t_m^c\right)\left(1 + p\right) = C'_l\, t_l^c \\
\left(c_{(l+1)1}\, t_1^c + \dots + c_{(l+1)l}\, t_l^c + v_{(l+1)(l+1)}\, t_{(l+1)}^c + \dots + v_{(l+1)m}\, t_m^c\right)\left(1 + p\right) = C'_{(l+1)}\, t_{(l+1)}^c \\
\dots \\
\left(c_{m1}\, t_1^c + \dots + c_{ml}\, t_l^c + v_{m(l+1)}\, t_{(l+1)}^c + \dots + v_{mm}\, t_m^c\right)\left(1 + p\right) = C'_m\, t_m^c \\
\left(c_{(m+1)1}\, t_1^c + \dots + c_{(m+1)l}\, t_l^c + v_{(m+1)(l+1)}\, t_{(l+1)}^c + \dots + v_{(m+1)m}\, t_m^c\right)\left(1 + p\right) = C'_{(m+1)}\, t_{(m+1)}^c \\
\dots \\
\left(c_{n1}\, t_1^c + \dots + c_{nl}\, t_l^c + v_{n(l+1)}\, t_{(l+1)}^c + \dots + v_{nm}\, t_m^c\right)\left(1 + p\right) = C'_n\, t_n^c \\
\sum_{i=1}^{n} C'_i = \sum_{i=1}^{n} \left(C'_i\, t_i^c\right)
\end{gathered}$$

At first sight, it may appear that not only the complete realization of the transformation, but the quantitative progress itself through which this transformation tends to be realized, could be represented by giving the model a multiyear basis. This is not the case. In such sort of model, each portion of capital would appear as immediately determining the prices of production in circuit *k* according to the price of production with which it emerges from $(k-1)$ (i.e. $c_{ij}\, t_{j(k-1)}^c$ or $v_{ij}\, t_{j(k-1)}^c$) though its price of production changes inside *k* (i.e. $c_{ij}\, t_{j(k)}^c \neq c_{ij}\, t_{j(k-1)}^c$ and $v_{ij}\, t_{j(k)}^c \neq v_{ij}\, t_{j(k-1)}^c$). Nevertheless, none of the specific portions of capital actually determines the price of production of the product in the way assumed here. The price of production of the means of production consumed during each circuit reappears in the price of production of the product through a specific meditation. As soon as the replacement of a means of production occurs at a modified price of production, this new price tends to replace the original one in the cost price of the production in course. Since the movements in the prices of production that take place inside each circuit fall beyond the reach of the representation we are dealing with, this tendency enters the representation as being directly realized. That is, $C'_i \, t^c_{i(k)}$ is determined by $\sum_{j=1}^{l} c_{ij} \, t^c_{j(k)}$ and not by $\sum_{j=1}^{l} c_{ij} \, t^c_{j(k-1)}$. In turn, the price of production that corresponds to the new value created during the necessary labor-time is determined by the price of production at which the means of subsistence the productive-laborers need to reproduce their labor-power emerge from that same circuit. There is no conservation of an existing value here, but the production of a completely new one. That is, $C'_i \, t^c_{i(k)}$ is determined by $\sum_{j=l+1}^{m} v_{ij} \, t^c_{j(k)}$, while $\sum_{j=l+1}^{m} v_{ij} \, t^c_{j(k-1)}$ plays no role whatsoever in its determination. Not even concerning advanced capital can the original price of production claim for a place if it changes during a circuit. The capital tied-up or released as this change takes place enters or leaves the determination of the annual rate of profit in that same circuit. Therefore, $C'_i \, t^c_{i(k)}$ is determined by $\left(\sum_{j=1}^{l} c_{ij} \, t^c_{j(k)} + \sum_{j=l+1}^{m} v_{ij} \, t^c_{j(k)}\right) p^c_{(k)}$ but not by $\left(\sum_{j=1}^{l} c_{ij} \, t^c_{j(k-1)} + \sum_{j=l+1}^{m} v_{ij} \, t^c_{j(k-1)}\right) p^c_{(k)}$.

Of course, such a meaningless model can always be constructed. And it would obviously render a set of dependent variables, as it is a determined system of simultaneous equations. Still, it will even show its emptiness in the self-incoherence of its results. Let us see why. The first step that value gives into its concrete form of price of production can be represented abstracted even from capital's necessity to reproduce its self-valorization since it involves a qualitative change that defines the object itself of this representation. Capital opens here its circuit as an accumulation of simple commodities, and therefore, of values, but emerges from it determined as a social totality fragmented into aliquot parts. Therefore, capital closes its circuit with commodities not only formally, but specifically, determined as their product, capital-commodities that enter circulation at their prices of production. On the contrary, we are now facing a stage in this transformation that does not introduce any qualitative difference other than the effect of the reproduction of the valorization process itself. Even the transformation of capital-commodities from materializations of equally valorized values to materializations of equally valorized values that have equally valorized themselves does not go beyond this reach. It is all about the progress towards the complete realization of the equalization of the rates of profit along the reproduction of capital's circuits. Consequently, the proper representation of this equalization presupposes now that the relations that correspond to the reproduction of capital's circuits are strictly fulfilled in the transit from one circuit to the next. The inclusion of any variable in the model according to its determination in a previous circuit when it has quantitatively changed in the current one will not impede capitals to appear with their valorization completely realized at the common rate of profit. But, at the same time, the total price of production of the two separated materialization under which profit enters circulation will disagree in their amount. The complete realization of all commodities at their prices of production will be in the same act the very negation of this realization. It is self-contradictory to assume that the equalization of profits has been completely achieved in one circuit, just to go on assuming that, *ceteris paribus*, the prices of production will change during the next one. Even though these "prices of production" produced by the model may asymptotically converge, thus appearing the opening one equal to the closing one, the model always fails its specific aim. It happens that the quantitative progress itself through which the transformation of values into prices of production tends to realize itself cannot be represented abstracted from the concrete forms it takes through competition. Hence, at the stage of its development we are considering here, the determination of prices of production can only be represented on a multiyear basis as the formal repetition of the single-year model. The only difference that can be introduced this way is the expanded reproduction of capital's valorization. And this expansion is completely alien to the determination itself of prices of production, provided it does not change the proportion that corresponds to each specific capital in total capital (which is a condition that any model that attempts to represent the determination of prices of production isolated from the concrete forms it takes in competition must satisfy). Let us return to our true subject.

Contrary to what happens when the transformation of values into prices of production is considered under its simplest form, none of the determinations that entered that transformation are immediately visible through the quantitative relations between their concrete forms. Therefore, no numerical example would add clarity to the point, beyond the cognition of the numerical results themselves. This cognition exceeds our specific necessity here.

The transformation of money into a product of capital

Since the price of production of a commodity is the concrete form of its value, it can only express itself as a certain amount of another commodity's use-value. Still, capital-commodities do not need to start by detaching one of them to turn it into their general equivalent, and therefore, into the immediately social product. On the contrary, capital-commodities presuppose money, as capital itself is but its necessary development. Still, the commodity determined as money, gold, can no longer act as the general equivalent of capital-commodities as the simple substantive form of social labor. It can act as this equivalent only insofar as it is itself the product of a capital that enters the formation of the general rate of profit as any other aliquot part of social capital. Gold becomes the incarnation of the immediate exchangeability as the substantive capacity of capital for valorizing itself on an equal basis. Thus, the antithetical determinations of the general equivalent - that make an use-value the expression of value and the concrete private labor that produces it the expression of abstract social labor - develop their concrete capitalist form. In it, the material product of a private concrete capital becomes the necessary expression of capital's valorization as a directly general social process.

Prices are in themselves the expression of exchange-value in money. Nevertheless, thus far we have abstracted from the mediation of the transformation of money-commodity itself into a product of capital in the quantitative determination of the prices of production. A "price of production” of the money-commodity is a contradiction in terms. Nevertheless, albeit gold is unable to express its value under the form of a price of production, its concrete capacity to express the value of the rest of commodities by functioning as their general equivalent is affected by its concrete determination as the product of capital. Depending on the relative organic composition and turnover rate the capitals that directly or indirectly produce the money-commodity have, and through the mediations that from here follow, its value could develop into a higher or lower exchangeability. Insofar as gold is used in some concrete production processes just as another means of production, this divergence will be reflected in the development of prices of production as any other. Still, this is not what really matters concerning the divergence in question. All capital-commodities express their prices of production in quantities of gold. Of course, an ounce of gold remains an ounce of gold whether commodities simply express in it their value or express this value under its concrete form of price of production. The same happens concerning a mass of gold produced during the year by a given quantity of living labor using a given quantity of dead labor. However, the divergence of the organic composition and turnover rate of the capitals that produce gold from the social averages suffices by itself to make all the relative manifestations of exchangeability in the same amount of gold to change. The simple divergence of the prices of production of all the ordinary capital-commodities from their values, and therefore these prices of production themselves, develop their concrete determination through the mediation of the aforementioned divergence concerning gold. The former divergences now manifest themselves insofar as their sources diverge with respect to the latter.

When the organic composition and turnover rate of the capitals that produce a certain commodity differ from the respective attributes of the capitals that produce in an opposite direction, they will add to each other in the direction that the simple specific difference has. Still, if those difference have the same direction, they will tend to cancel each other. Consequently, the price of production of a commodity produced by capitals with an organic composition and turnover rate higher (lower) than the social average can take concrete form as a magnitude bellow (above) the value it contents. This can happen as soon as the organic composition and turnover rate of the capital that produces gold are even higher (lower) than the social average. When the net effect of all the determinations involved accidentally makes the simple prices of production of a specific commodity to move in the same direction and degree the exchangeability of gold as a product of capital does, the value of that commodity will take its completely developed concrete form of price of production as a magnitude identical to itself. And this will occur however much the capital that produces that commodity differs from the social average in its organic power to valorize itself.

This concrete determination of the prices of production manifests itself concerning the total social capital. It does so through the relation between the average organic composition and turnover rate of total social capital with respect to the same attributes in the case of gold. Disregarding an accidental coincidence, the value of the total social product ceases to appear as an unchanged magnitude of gold as soon as it reaches the present point in the development of its concrete form as the price of production of the total social capital that annually emerges from its process of valorization.

Let us assume that the commodity that directly or through its signs acts as money, has no other use-value than this. Let us also assume that this use-value becomes completely exhausted during the year in which it goes into circulation. On these basis, we can consider now that the special sphere *n* does not produce articles for the individual consumption of the capitalists but the money-commodity. To keep at sight the whole development of the transformation, we will still use the expression $c_{ij}\,t^{c}_{j}$, etc. for the previously considered form of the prices of production, although the coefficients t^{c}_{j} enter here with their own determination already realized. Values quantitatively take now their concrete form of prices of production as:

$$\left(c_{11} t^c_1 / t^c_n + \dots + c_{1l} / t^c_n + v_{1(l+1)} t^c_{(l+1)} / t^c_n + \dots + v_{1m} t^c_m / t^c_n\right)\left(1 + p'\right) = C'_1 t^c_1 / t^c_n$$

...

$$\left(c_{l1} t^c_1 / t^c_n + \dots + c_{ll} t^c_l / t^c_n + v_{l(l+1)} t^c_{(l+1)} / t^c_n + \dots + v_{lm} t^c_m / t^c_n\right)\left(1 + p'\right) = C'_l t^c_l / t^c_n$$

$$\begin{aligned}\big(c_{(l+1)1} t^c_1 / t^c_n + \dots + c_{(l+1)l} t^c_l / t^c_n + v_{(l+1)(l+1)} t^c_{(l+1)} / t^c_n + \dots +\\ + v_{(l+1)m} t^c_m / t^c_n\big)\left(1 + p'\right) = C'_{(l+1)} t^c_{(l+1)} / t^c_n\end{aligned}$$

...

$$\left(c_{m1} t^c_1 / t^c_n + \dots + c_{ml} t^c_l / t^c_n + v_{m(l+1)} t^c_{(l+1)} / t^c_n + \dots + v_{mm} t^c_m / t^c_n\right)\left(1 + p'\right) = C'_m t^c_m / t^c_n$$

$$\begin{aligned}\big(c_{(m+1)1} t^c_1 / t^c_n + \dots + c_{(m+1)l} t^c_l / t^c_n + v_{(m+1)(l+1)} t^c_{(l+1)} / t^c_n + \dots +\\ + v_{(m+1)m} t^c_m / t^c_n\big)\left(1 + p'\right) = C'_{(m+1)} t^c_{(m+1)} / t^c_n\end{aligned}$$

...

$$\left(c_{n1} t^c_1 / t^c_n + \dots + c_{nl} t^c_l / t^c_n + v_{n(l+1)} t^c_{(l+1)} / t^c_n + \dots + v_{nm} t^c_m / t^c_n\right)\left(1 + p'\right) = C'_n$$

$$\sum_{i=1}^{n} C'_i = \sum_{i=1}^{n} \left(C'_i t^c_i\right) / t^c_n$$

Given the velocity of the currency of money, a different quantity of it will be needed to make the product of the same amount of materialized social labor circulate when the value of this product develops into a mass of price of production that differs from it in its magnitude. If this change in the quantity of money is satisfied through a change in the quantity of gold that enters circulation, it will therefore affect the scale of gold production. In turn, this change will imply a reallocation of social capital into its concrete specific forms, therefore leading to a general movement in the prices of production. Nevertheless, at this stage of our development of the determinations of these prices we can assume that the change in the quantity of money takes place through the amount of money-signs placed in circulation. On doing so, we can leave the question of the effect of a material change risen by the transformation itself upon these very transformation out, until we face it where it belongs in general, competition.

The realization of capital-commodities in competition

In its developed concrete form, the general rate of profit is the synthetic form the capitalist regulation of the social metabolism process takes. Through its formation, capitalist society allocates its total labor-power and, therefore, its total capacity for consuming into their concrete material forms. Still, capitalism arises as the most developed historical negation of the direct regulation of human life. It is an autonomously regulated system. Therefore, the general rate of profit can only realize its determination by negating itself as the immediate form of the general social regulation to affirm itself through the action of the individual capitals, that is, in an indirect way.

In commodity-producing society, material production produces at the same time the general social relation. Consequently, this social relation necessarily reaches its complete realization through the exchange of the material products as equivalent materializations of the same social content. In the proportion that the abstract labor materialized in a commodity is not determined as socially necessary, this commodity will enter exchange lacking the power to attract other commodities as its equivalents. Conversely, when a concrete labor has been performed short of the corresponding social necessity for its product, the abstract labor materialized in this product enters exchange determined as the equivalent of a greater amount of social labor. Although commodities are completely determined as materializations of a certain amount of socially necessary abstract labor in the very moment they are produced, their condition as such only becomes visible when they are actually exchanged. Only then their producers can recognize the concrete labor they have performed as exceeding or falling short of the respective social necessity, as they lose or gain in their power to exercise their general social relation, and therefore, to produce their own lives. And, only through this recognition, the specific social determination of their products as values can take its concrete shape in the movement of social labor from one concrete form to another.

In any social metabolism process, the magnitude of each social necessity includes, among its determinants, the magnitude of the social labor-power that has to be allocated into the corresponding concrete form to satisfy it. In general, this is an inverse relation. But, in this autonomously regulated social system, it is not an immediate relation. As any determination that concerns the allocation of concrete labor in commodity-producing society, it is mediated by the form itself in which the abstract labor materialized in each commodity is represented as socially necessary in the general social relation.

The socially necessary abstract labor embodied in capital-commodities completes its determination as such by making these commodities circulate as equivalent materializations of equally valorized capitals. Given the differences in the organic composition and in the turnover rate of the variable part of the capitals that valorize themselves in each special sphere of social production, capital-commodities do not realize their determination as materializations of socially necessary abstract labor if they go into circulation at their values. In this case, the capitals with the highest organic composition and the slowest turnover find their power to exercise their general social relation and, therefore, to produce their own "lives" as the alienated concrete subjects of the social metabolism process, diminished. Those capitals with the opposite attributes find these capacities increased. In pursuit of realizing their necessity as values that valorize themselves in an equal proportion, capitals move away from the spheres where they have the highest organic composition and the slowest turnover to get into the spheres that allow the opposite attributes. The circulation of commodities has thus acquired its first specific determination as the competition among capitals.

Following the movement of capitals from one sphere to another, social production changes in each corresponding proportion. Still, if commodities were circulating up to that moment at their values, the social necessity for each of them was accordingly determined. And, in commodity-production, social necessity means effective demand. Hence, now, it is exceeded in those spheres where capital has been attracted and insufficiently covered in those spheres from where capital has been expelled. The necessity of capitals to equally valorize themselves takes shape at this point in the fall of the magnitude in which the abstract labor materialized in the commodities with expanded production is represented as socially necessary in exchange. The opposite movement takes place in the market-prices of the commodities with a diminished production. The capitals that undergo the downward movement can no longer appropriate the whole surplus-value they directly extract from their wage-laborers. Those that experience the upward movement start to appropriate a larger amount of surplus-value than that they directly extract. All the surplus-value that the former capitals can lose is that which the latter capitals have to win, and vice versa. Beyond this point, the movements in question cease to be the concrete form through which capitals determine themselves as aliquot parts of total social capital to become the negation of this determination. Therefore, the transformation of values into prices of production necessarily takes shape through a change in the magnitude of the social necessity for each use-value. From which, that transformation takes shape through a change in the material forms of the social production, which means, a different allocation of the social labor-power into its concrete forms.

It is only through this material change that the transformation of values into prices of production affects total social capital as such. According to its general determination, this transformation takes shape by expanding the production of the spheres with a lower organic composition and faster turnover of capital, while it contracts the production of the capitals with the highest organic composition and lowest turnover rate. Nevertheless, this general determination may present some specific movements that are opposed to it. Some commodities may get their production expanded beyond the general proportion as they substitute other commodities with an alternative use-value, once an unfavorable proportion between their values becomes inverted at their prices of production. This sort of inversion can even make way for commodities excluded from production at their values, as well as it can completely exclude others from production. Besides, some commodities may get their production increased even though their prices of production are higher than their values. For example, this can happen when the price of production of an alternative use-value grows in an even greater degree above its value, causing its substitution; or when the fall in the price of production of another commodity that is associated with them in consumption outdoes their higher price.

All these changes do not involve a change in the productivity of labor that the social capital can put into action. This productivity emerges from the material conditions in which each production is performed in a given moment. And these conditions have remained untouched. So, thus far, it is only about changes in the average organic composition that result from changes in the weight with which capitals with different organic compositions enter that average. Nevertheless, if the scale in which a specific commodity is produced changes, a change in the technical conditions of its production may result. An increased (diminished) scale can create by itself the conditions for a higher (lower) productivity, provided the consequent increase (decrease) in the specific organic composition does not offset the initial increase (decrease) in the scale. Still, the transformation of surplus-value into average profit determines the productivity of labor beyond this change in scales. Let us consider a productive technique excluded from production since it requires more labor to produce the same use-value than the technique in use. Nevertheless, the lower organic composition that corresponds to it may result in a price of production lower than the one that corresponds to the technique in use up to that moment. As soon as commodities circulate at their prices of production, these techniques are shifted, causing the productivity of labor to move backwards. This is a specific obstacle capitalist regulation of social life rises against its own general trend towards the increase of productivity of labor, as this increase is the source of relative surplus-value. Since techniques that involve a lower productivity are put into action, a lower general rate of surplus-value but a higher general rate of profit result.

Given the magnitude of society's total capital, the general expansion of the capitals with the lower organic compositions and the contraction of those with the higher ones puts a greater amount of labor-power into action, while the rate of surplus value remains unchanged. From which, the total amount of surplus-value increases. Concerning the eventual specific introduction of techniques with a lower productivity of labor, the expanded base upon which surplus-value is produced tends to counteract the fall in its rate. Consequently, in general, total social capital appropriates an increased amount of surplus-value just because this surplus-value develops its concrete form of average profit. Always considering a given amount of total social capital, this increased surplus-value results in an increased general rate of profit.

We have finally completed the development of values into their concrete form of prices of production. To represent the annual valorization of social capital including the determinations that emerge from its realization through competition we must start by accounting for all the concrete forms that configure competition itself. Obviously, this specification only fits here in its most abstract form; that is, as a mere enunciation of the possible relations involved concerning the transformation of values into prices of production itself, that even excludes the eventual substitution of a technique by another. Following from the stage we reached before we specifically considered the mediation of money, and calling q_i the factor that reflects the material changes that occur in each element - so the original values appear now developed into their concrete forms of prices of production of a mass of each use-value *i* that differs from the original one as $c_{ij} t_j^{cc} q_{ij}, v_{ij} t_j^{cc} q_{ij}, C'_i t_i^{cc} q_i$ - and p^{cc} the completely developed concrete form that the average rate of profit takes, we have:

$$\left(c_{11} t_1^{cc} q_{11} + \dots + c_{1l} t_l^{cc} q_{1l} + v_{1(l+1)} t_{(l+1)}^{cc} q_{1(l+1)} + \dots + v_{1m} t_m^{cc} q_{1m}\right)\left(1 + p^c\right) = \sum_{i=1}^{n} \left(c_{i1} t_1^{cc} q_{i1}\right)$$

...

$$\left(c_{l1} t_1^{cc} q_{l1} + \dots + c_{ll} t_l^{cc} q_{ll} + v_{l(l+1)} t_{(l+1)}^{cc} q_{l(l+1)} + \dots + v_{lm} t_m^{cc} q_{lm}\right)\left(1 + p^c\right) = \sum_{i=1}^{n} \left(c_{il} t_l^{cc} q_{il}\right)$$

$$\left(c_{(l+1)1} t_1^{cc} q_{(l+1)1} + \dots + c_{(l+1)l} t_l^{cc} q_{(l+1)l} + v_{(l+1)(l+1)} t_{(l+1)}^{cc} q_{(l+1)(l+1)} + \dots + \right.$$
$$\left. + v_{(l+1)m} t_m^{cc} q_{(l+1)m}\right)\left(1 + p^c\right) = \sum_{i=1}^{n} \left(v_{i(l+1)} t_{(l+1)}^{cc} q_{i(l+1)}\right)$$

...

$$\left(c_{m1} t_1^{cc} q_{m1} + \dots + c_{ml} t_l^{cc} q_{ml} + v_{m(l+1)} t_{(l+1)}^{cc} q_{m(l+1)} + \dots + v_{mm} t_m^{cc} q_{mm}\right)\left(1 + p^c\right) = \sum_{i=1}^{n} \left(v_{im} t_m^{cc} q_{im}\right)$$

$$\left(c_{(m+1)1} t_1^{cc} q_{(m+1)1} + \dots + c_{(m+1)l} t_l^{cc} q_{(m+1)l} + v_{(m+1)(l+1)} t_{(l+1)}^{cc} q_{(m+1)(l+1)} + \dots + \right.$$
$$\left. + v_{(m+1)m} t_m^{cc} q_{(m+1)m}\right)\left(1 + p^c\right) = C'_{(m+1)} t_{(m+1)}^{cc} q_{(m+1)}$$

...

$$\left(c_{n1} t_1^{cc} q_{n1} + \dots + c_{nl} t_l^{cc} q_{nl} + v_{n(l+1)} t_{(l+1)}^{cc} q_{n(l+1)} + \dots + v_{nm} t_m^{cc} q_{nm}\right)\left(1 + p^c\right) = C'_n t_n^{cc} q_n$$

$$\sum_{i=1}^{n} C'_i q_i = \sum_{j=1}^{l} \sum_{i=1}^{n} \left(c_{ij} t_j^{cc} q_{ij}\right) + \sum_{j=(l+1)}^{m} \sum_{i=1}^{n} \left(v_{ij} t_j^{cc} q_{ij}\right) + \sum_{i=(m+1)}^{n} \left(C'_i t_i^{cc} q_i\right)$$

$$q_{11} = f\left(t_1^{cc}, \dots, t_n^{cc}\right)$$

...

$$q_{nm} = f\left(t_1^{cc}, \dots, t_n^{cc}\right)$$

$$q_{(m+1)} = f\left(t_1^{cc}, \dots, t_n^{cc}\right)$$

...

$$q_n = f\left(t_1^{cc}, \dots, t_n^{cc}\right)$$

No specificity arises from the transformation of the commodity that acts as money into a capital-commodity concerning its realization through competition. There is no need then to represent its quantitative determinations here.

Total social capital and conscious revolutionary action

We have followed commodities through their development into their specific form of capital-commodities. We have seen how commodities - the products of socially necessary abstract labor represented as the capacity of these products for relating among themselves in exchange thus socially relating their producers - have transformed themselves into the real products of capital. Through this transformation, the materialized fetishistic general social relation becomes the immediate concrete subject of social life itself, producing human beings as its personifications and alienating all human potencies as its potencies. The social metabolism process now regulates itself through the accumulation of capital. As such constant reproduction of the self-valorization of substantive value, the general regulation of social life lacks any qualitative determination other than the equal valorization of the capitals advanced to perform social production. Surplus-value takes concrete form of average profit. Commodities are no longer exchangeable as equivalent materializations of socially necessary abstract labor, but as materialization of this labor which is represented as the capacity of capital-commodities for being exchanged as equivalent materializations of equally valorized values. With the reproduction of the valorization process, capital-commodities become determined as equivalent materializations of equally valorized values that have equally valorized themselves. The value of commodities thus has completely metamorphosed itself into the price of production of capital-commodities.

On reaching this point, not a single quantitative trace of the values of capital-commodities remains immediately recognizable in these values' concrete forms of prices of production. This happens whether a singular commodity, a singular capital, the specific parts of total social capital or this capital itself, and whether prices of production as such or their changes, are considered. From an equally external point of view, average profit and its rate appear to be alien to any organic determination, and even to any simple formal determination, of capital's valorization by its capacity for producing surplus-value. Nevertheless, these appearances will not fool us when the moment comes to take action on them. We have already appropriated in thought the complete necessity of the prices of production by following it step by step along its development. We have thus discovered that the apparent self-determination of this prices is not such but the necessary concrete form through which the socially necessary abstract labor materialized in capital-commodities is represented as the capacity of these commodities to act as the general social relation. At the same time, we have discovered how capital's capacity for appropriating surplus-value necessarily appears with its magnitude distorted and its laws inverted under its concrete form of the general rate of profit.

Now we can extend Marx's conclusions to the complete development of surplus-value into average profit as follows: "What competition does *not* show, however, is the determination of value, which dominates the movement of production; and the values that lie beneath the prices of production and that determine them in the last instance. Competition, on the other hand, shows: 1) the average profits, which are independent of the organic composition of capital in the different spheres of production, and therefore also of the mass of living labour appropriated by any given capital in any given sphere of exploitation" - and we add, whose rate differs from the relation between total surplus-value and total capital; "2) the rise and fall of prices of production caused by changes in the level of wages, a phenomenon which at first glance completely contradicts the value relations of commodities" - and we add, that appear to be free from any necessary determination; "3) the fluctuations of market-prices, which reduce the average market-price of commodities in a given period of time, not to the market-*value*, but to a very different market-price of production, which diverges considerably from this market-value" - and we add, whose total amounts also diverge for the social product, constant capital, variable capital and surplus-value; 4) the organic relation between the total constant capital and the total variable capital annually consumed and between the total annual profit and the total variable capital annually consumed, as completely alien to the capacity of capital for valorizing itself. "All these phenomena *seem* to contradict the determination of value by labour-time as much as the nature of surplus-value consisting of unpaid surplus-labour. *Thus everything appears reversed in competition*. The final pattern of economic relations as seen on the surface, in their real existence and consequently in the conceptions by which the bearers and agents of these relations seek to understand them, is very much different from, and indeed quite the reverse of, their inner but concealed essential pattern and the conception corresponding to it.” (Marx, Capital III, pp. 208-9)

Not in vain, capital accumulation autonomously regulates the social metabolism process behind the backs of the individuals. Conscious action rules inside each individual capital, but only as far as it is a necessary concrete form that the general autonomous regulation takes. Such is the field where the appearances of competition belong. Capital accumulation is, in itself, the very negation of the conscious regulation of this process.

Since it is empty of any immediate necessity other than the purely quantitative of increasing its own value, capital cannot find in itself a qualitative limit to the expansion of its valorization process. Hence, the insatiable thirst of human blood and flesh it has. Still, it can only go on with its expansion by making the production of relative surplus-value its main source of valorization. The production of surplus-value can only take concrete form through the unlimited concentration of capital and the control of production and consumption by science as a social potency personified in the collective-laborer (and, therefore, in the proletariat itself as a class). But this twofold concrete form is, in itself, the very negation of private property upon the social means of production and of the unconscious regulation of human life through the proletariat’s action alienated as a capital’s potency (as any potency of the proletariat is). It is, in itself, the very annihilation of capitalism through its own development, into the conscious regulation of the social metabolism process by the therefore freely associated individuals, into socialism or communism.

It is about the production of the conscious regulation of the social metabolism process as the realization of the proletariat’s most genuine historical determination. Therefore, it is about an action of the proletariat that needs to be, in itself, a conscious action. It is about a revolutionary action that regulates itself through the cognition of its own necessity by reproducing it in thought, thus overcoming the alienation of the proletariat’s consciousness inherent in any interpretation of the world. And, as this action directly concerns *total social capital*, it is about *the political revolutionary action of the proletariat*.

Total social capital reaches its real determination overcoming any formal aggregation of individual capitals, only as simple commodities are turned into capital-commodities through the transformation of surplus-value into average profit. From this transformation on, our materialized general social relation takes a prices of production-form. To consciously personify the revolutionary potency our general social relation carries in itself, we need to rule our action by appropriating in thought the determinations of these prices of production, as far as our action becomes itself a specific form for those determinations to be realized. Since prices of production inhere in the general form itself that our general social relation takes, there is hardly a concrete form of revolutionary action and, furthermore, of the proletariat’s political action in general, that is not, in itself, such realization. Just to point out some obvious examples, these concrete actions range from the struggles through which the value of labor-power takes concrete form as wages, or the question of scientific priorities through which the development of the productivity of labor takes concrete form, to the transformation of capital into a directly collective property and, therefore, a directly collective human alienated potency, inside a national or international ambit of capital accumulation through a social revolution.

In other words, it is not about interpreting Marx’s texts on the transformation of values into prices of production, whichever form this interpretation takes. It is about facing capital in reality, as it directly concerns through this transformation our revolutionary conscious action, searching in it for the necessity of this action, to rule it by reproducing this necessity in thought. And it is here where Marx’s advances in reproducing through thought the specificity of capitalist society come in: we expand the reach of our own advance through this reproduction as far as it can be developed, not as an original process of cognition but, as a process of recognition from the social point of view, by critically using *Capital* as its support. Which means that this support has to be renewed each time we face a specific real concrete form that concerns our action, as we can only reproduce this form in thought provided we do not isolate it from the complete development of its own necessity, that starts to emerge from its simplest forms.

Therefore, from the point of view of present-day conscious revolutionary action, it is not about "understanding" exploitation or "understanding" the movements in prices. "Understanding" exploitation takes us nowhere concerning this action. It does not follow the necessity inherent in exploitation through its complete development into its concrete forms, up to facing it as a potency which has our political action - and more precisely, our political action determined as an action that has needed to follow all this path to become a conscious action - as its own necessary form of realizing itself into its self-annihilation. And, certainly, in a more direct or indirect way, exploitation always takes concrete form through prices of production. Instead, "understanding" turns this real abstract form that shapes itself in prices of production, the expropriation of surplus-value, capitalist exploitation, into a pure abstraction. Reciprocally, "understanding" the movements in prices isolates these movements from the complete development of their necessity, thus turning these concrete forms that capitalist exploitation takes, into another set of pure abstractions. As such, these abstractions do not go beyond the appearances of competition that really concern the action of those who personify capital's historical necessity as a mere process of expropriation of surplus-value. But the point concerning conscious revolutionary action is to personify capital's historical opposite necessity, that of superseding itself into a free human society.
